# **PREFACE**

"Inorganic Chemistry for Competitions" has primarily, been written with the aim of meeting the needs and interests of students seeking admission to professional courses especially in engineering and medical. This is an age of tough competition where only the best survives. No doubt, the syllabus for various entrance tests is nearly the same as for intermediate or 10+2 examinations, yet even good students fail to qualify as the standard of these tests is comparatively high and seats in engineering and medical colleges are limited.

The present trend in competitive examinations is the stress on an objective rather than subjective treatment of the subject matter. A critical scrutiny of the question papers of previous years of various entrance tests reveals that a variety of questions such as very short answer type, short answer type, fill in the blanks, true and false, match the column, multiple choice, numerical type are usually asked. In order to answer these questions, the students must be well equipped with thorough knowledge of the subject and its application. With these objectives in mind, I have tried to present inorganic chemistry for competitions covering whole of the syllabus of nearly all the competitions. The complete subject matter has been arranged in a systematic manner. Every topic has been dealt precisely and to the point in a simple and understandable language. Things have been explained with proper reasoning wherever possible. A good number of illustrations and solved problems based on structure and properties including numerical problems have been provided to understand the theoretical aspect. Due emphasis has been given on group discussions of various groups of periodic table. Flow-sheet diagrams have been provided to simplify the extraction of various metals, preparation of a number of compounds and their properties. At the end of each chapter, a good number of questions of various types have been given for self-assessment. It is my belief that students will be duly rewarded if they attempt these questions honestly and sincerely after learning the particular topic. Necessary hints have been given wherever it is felt necessary.

Human efforts are never perfect. In spite of my best efforts, I am aware of the possible errors and omissions that have escaped my notice. I shall, therefore, be extremely thankful to the learned teachers who will extend their cooperation by sending their valuable criticism, suggestions and observations for further improvement of the book. I consider it my duty to pay thanks to the authors and publishers of the books which I have consulted during the preparation of the manuscript.

My sincere thanks are due to Shri Manoj Kumar Bathla, Proprietor, M/s G.R. Bathla & Sons, Shri Shiv Charan Sohal (Artist) for the whole-hearted cooperation in the preparation and publication of this book. I am also thankful to Dr. A.K. Virmani and Dr. A.S. Singh for their encouragement, cooperation and guidance in the preparation of the manuscript of this book. Finally, I thank my wife and children for the help they have extended in proof-reading.

June, 2000 O.P. TANDON

### Classification of Elements and Periodicity in Properties

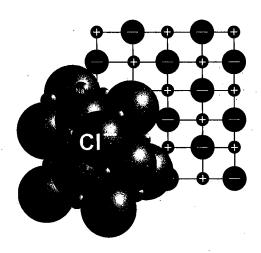

1 - 67

1.1 Introduction (1), 1.2 Earlier Attempts of Classification of Elements (2), 1.3 Mendeleev's Periodic Law and Original Periodic Table (3), 1.4 Modern Periodic Law and Modified Form of Mendeleev's Periodic Table (4), 1.5 Naming the Elements (9), 1.6 Electronic Configurations and the Periodic Table (11), Periodic Table of the Elements (Long Form—Representing Electron Configurations) (14), 1.7 Extended or Long Form of Periodic Table (17), Periodic Table of the Elements (Long Form) (18), 1.8 Position of an Element on the Basis of Electronic Configuration (22), 1.9 Atomic Properties or Periodic Properties of Elements (23), 1.10 The Screening Effect or Shielding Effect (24), 1.11 Effective Nuclear Charge (24), 1.12 Atomic Radius (24), 1.13 Ionic Radius (28), 1.14 Ionisation Enthalpy or Ionisation Potential (29), 1.15 Electron Gain Enthalpy or Electron Affinity (31), 1.16 Electronegativity (33), 1.17 Some other Properties in which Periodicity is Observed (34), Some Solved Problems (37), Summary and Important Points to Remember (41), Practice Problems (44), Answers (48), Illustrations of Objective Questions (49), Objective Questions (51), Answers (59), Objective Questions for IIT Aspirants (60), Answers (62), Matrix Matching Questions for IIT Aspirants (62), Answers (63), Assertion-Reason Type Questions (63), Answers (63), Thought Type Questions (64), Answers (66), Integer Answer Type Questions (67), Answers (67).

### **Chemical Bonding**

68 - 156

2.1 Introduction (68), 2.2 Cause of Chemical Combination (69), 2.3 Lewis Symbols of Elements (70), 2.4 Electronic Theory of Valency (70), 2.5 Electrovalent or Ionic Bond (70), 2.6 Determination of Lattice Energy (73), 2.7 Types of Ions (74), 2.8 Method of Writing Formula of an Ionic Compound (74), 2.9 Difference between Atoms and Ions (75), 2.10 General Characteristics of Electrovalent Compounds (75), 2.11 Variable Electrovalency (77), 2.12 Covalent Bond (78), 2.13 Covalency (79), 2.14 Covalent Compounds (80), 2.15 Covalent Molecules of Elements (80), 2.16 Characteristics of Covalent Compounds (80), 2.17 Comparison between Ionic and Covalent Bonds (81), 2.18 Comparison between Ionic and Covalent Compounds

(81), 2.19 Coordinate Bond (81), 2.20 Failure of Octet Rule (83), 2.21 Lewis Formulae for Molecules and Polyatomic Ions (84), 2.22 Formal Charge (88), 2.23 Polarity of Covalent Bond (89), 2.24 Dipole Moment (90), 2.25 Polarisation (Change of Ionic Character to Covalent Character) (92), 2.26 Hydrogen Bonding (93), 2.27 Modern Concept of Covalent Bond (95), 2.28 Hybridization (97), 2.29 Resonance (101), 2.30 Prediction of Geometry (Shape) of Covalent Molecules (102), 2.31 Valence Shell Electron Pair Repulsion (VSEPR) Theory (104), 2.32 Bond Characteristics (107), 2.33 Odd Electron Bonds (109), 2.34 Molecular Orbital Theory (109), 2.35 Metallic Bonding (118), Some Solved Problems (119), Summary and Important Points to Remember (123), Practice Problems (128), Answers (132), Illustrations of Objective Questions (134), Objective Questions (136), Answers (148), Objective Question-Reason Type Questions (152), Answers (153), Thought Type Questions (153), Answers (156), Integer Answer Type Questions (156), Answers (156).

Acids and Bases 157 – 177

3.1 Introduction (157), 3.2 Arrhenius Concept (157), 3.3 Bronsted-Lowry Concept (159), 3.4 Lewis Concept (161), 3.5 The Lux-Flood Concept (163), 3.6 Usanovich Concept (163), 3.7 Hard and Soft Acids and Bases (163), 3.8 Some General Trends in Acidic and Basic Properties (164), Summary and Important Points to Remember (166), Practice Problems (168), Answers (170), Illustrations of Objective Questions (171), Objective Questions (172), Answers (175), Objective Questions for IIT Aspirants (175), Answers (176), Answers (176), Answers (176), Answers (176), Integer Answer Type Questions (177), Answers (177).

# General Principles of Extraction of Metals

178 - 208

4.1 Occurrence of Elements (178), 4.2 Occurrence of Metals (180), 4.3 Metallurgy (181), 4.4 Concentration or Dressing of the Ore (181), 4.5 Extraction or Isolation of Crude Metals (183), 4.6 Thermodynamic Principles of Metallurgy (186), 4.7 Applications of Ellingham Diagram in Pyrometallurgy (188), 4.8 Third Operation—Refining or Purification (189), 4.9 Furnaces (191), 4.10 Refractory Materials (192), Mineral Resources of India (193), Some Solved Problems (193), Summary and Important Points to Remember (195), Practice Problems (198), Answers (199), Illustrations of Objective Questions (200), Objective Questions (201), Answers (205), Objective Questions for IIT Aspirants (206), Answers (207), Assertion-Reason Type Questions (207), Answers (207), Integer Answer Type Questions (208), Answers (208).

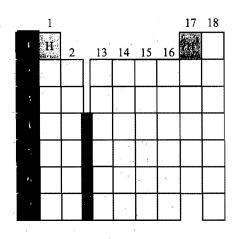

# Revision Exercise-1 (Chapter 1 to 4)

209 - 214

# Hydrogen and its Compounds (ns1)

215-265

5.1 Position of Hydrogen in Periodic Table (216), 5.2 Discovery and Occurrence (217), 5.3 Preparation (217), 5.4 Manufacture of Hydrogen (219), 5.5 Properties of Hydrogen (220), 5.6 Industrial Applications (221), 5.6.1 Hydrogen Economy (222), 5.7 Hydrides (223), 5.8 Special Forms of Hydrogen (227), 5.9 Isotopes of Hydrogen (227), 5.10 Heavy Hydrogen or Deuterium (228), 5.11 Tritium ( $^3_1$ H.or  $^3_1$ T) (229), 5.12 Heavy Water or Deuterium Oxide (D<sub>2</sub>O) (230), 5.13 Water (231), 5.14 Hard and Soft Water (234), 5.15 Hydrogen Peroxide (236), Summary and Important Points to Remember (245), Practice Problems (248), Answers (250), Illustrations of Objective Questions (251), Objective Questions (253), Answers (259), Objective Questions for IIT Aspirants (260), Answers (260), Matrix Matching Questions (261), Answers (260), Answers (260), Answers (261), Answers (263), Brain Storming Problems (263), Integer Answer Type Questions (265), Answers (265).

# Alkali Metals and their Compounds (Group IA or 1, ns 1)

266-315

6.1 Position of Alkali Metals in Periodic Table (266), 6.2 Abnormal Behaviour of Lithium (272), 6.2.1 Diagonal Relationship: Similarities with Magnesium (272), 6.3 Lithium (273), 6.4 Sodium (276), 6.5 Compounds of Sodium (278), 6.6 Potassium (289), Summary and Important Points to Remember (293), Practice Problems (296), Answers (299), Illustrations of Objective Questions (300), Objective Questions (302), Answers (308), Objective Questions for IIT Aspirants (309), Answers (310), Matrix Matching Questions for IIT Aspirants (311), Answers (311), Answers (312), Thought Type Questions (312), Answers (313), Brain Storming Problems (313), Integer Answer Type Questions (315), Answers (315).

# Alkaline Earth Metals and their Compounds (Group IIA or 2, ne2)

316 - 356

7.1 Position of Alkaline Earth Metals in Periodic Table (316), 7.2 Solubility of Compounds of Alkaline Earth Metals (322), 7.3 Difference between Alkaline Earth Metals and Alkali Metals (323), 7.4 Abnormal Behaviour of Beryllium (323), 7.5 Similarities (Diagonal Relationship) between Beryllium and Aluminium (324), 7.6 Magnesium (325), 7.7 Calcium (329), 7.8 Compounds of Barium (334), Some Solved Problems (335), Summary and Important Points to Remember (337), Practice Problems (340), Answers (343), Illustrations of Objective Questions (344), Objective Questions (346), Answers (351), Objective Questions for IIT Aspirants (352), Answers (353), Matrix Matching Questions for IIT Aspirants (354), Answers (354), Assertion-Reason Type Questions (354), Answers (355), Thought Type Questions (355), Answers (356), Integer Answer Type Questions (356), Answers (356).

# ◆ Revision Exercise-2 (Chapter 5 to 7)

357 - 361

# Elements of Group IIIA or 13 [The Boron Family (ns2 np1)] (Boron and Aluminium)

362 - 407

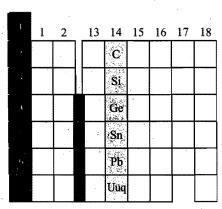

8.1 General Characteristics of Group IIIA or 13 Elements (362), 8.2 Abnormal Behaviour of Boron (368), 8.3 Comparison of Boron and Aluminium (368), 8.4 Diagonal Relationship of Boron and Silicon (370), 8.5 Boron (371), 8.6 Compounds of Boron (372), 8.7 Aluminium (378), 8.8 Compounds of Aluminium (382), 8.9 Goldschmidt's Alumino-Thermic Process (384), Some Solved Problems (384), Summary and Important Points to Remember (387), Practice Problems (390), Answers (393), Illustrations of Objective Questions (394), Objective Questions (396), Answers (402), Objective Questions for IIT Aspirants (403), Answers (404), Assertion-Reason Type Questions (404), Answers (405), Thought Type Questions (405), Answers (406), Brain Storming Problems (406), Integer Answer Type Questions (407), Answers (407).

# Elements of Group IVA or 14 (Elements of Carbon Family, ns<sup>2</sup>np<sup>2</sup>)

408 - 460

9.1 Position in Periodic Table (408), 9.2 Comparison of Carbon and Silicon (412), 9.3 Comparison of Tin and Lead (414), 9.4 Carbon (415), 9.5 Compounds of Carbon (418), 9.6 Silicon (425), 9.7 Compounds of Silicon (426), 9.8 Tin (430), 9.9 Compounds of Tin (431), 9.10 Lead or Plumbum (433), 9.11 Compounds of Lead (435), Some Solved Problems (437), Summary and Important Points to Remember (440), Practice Problems (443), Answers (446), Illustrations of Objective Questions (448), Objective Questions (449), Answers (455), Objective Questions for IIT Aspirants (456), Answers (457), Assertion-Reason Type Questions (457), Answers (458), Thought Type Questions (458), Answers (459), Brain Storming Problems (459), Integer Answer Type Questions (460), Answers (460).

### 461 - 529

### (Elements of Nitrogen and Phosphorus Family, $ns^2np^3$ )

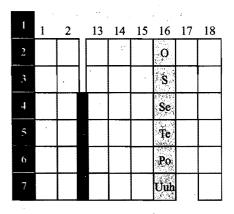

10.1 Position in Periodic Table (461), 10.2 Abnormal Behaviour of Nitrogen (466), 10.3 Nitrogen (N<sub>2</sub>) (467), 10.4 Important Compounds of Nitrogen (469), 10.5 Nitrates (485), 10.6 Phosphorus (486), 10.7 Compounds of Phosphorus (489), 10.8 Arsenious Oxide or Arsenic Trioxide (497), 10.9 Fertilizers (498), Some Solved Problems (501), Summary and Important Points to Remember (504), Practice Problems (509), Answers (513), Illustrations of Objective Questions (515), Objective Questions (517), Answers (524), Objective Questions for IIT Aspirants (524), Answers (525), Assertion-Reason Type Questions (526), Answers (526), Thought Type Questions (526), Answers (528), Brain Storming Problems (528), Integer Answer Type Questions (529), Answers (529).

# Elements of Group VIA or 16 (The Oxygen Family, ns<sup>2</sup>np<sup>4</sup>)

530 - 575

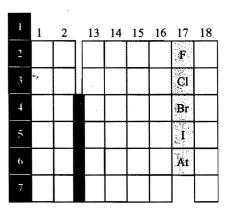

11.1 Position in Periodic Table (530), 11.2 Abnormal Behaviour of Oxygen (535), 11.3 Dissimilarities between Oxygen and Sulphur (535), 11.4 Oxygen (536), 11.5 Oxides (537), 11.6 Ozone (539), 11.7 Sulphur (542), 11.8 Compounds of Sulphur (543), Some Solved Problems (555), Summary and Important Points to Remember (557), Practice Problems (561), Answers (564), Illustrations of Objective Questions (565), Objective Questions (567), Answers (571), Objective Questions for IIT Aspirants (572), Answers (573), Assertion-Reason Type Questions (573), Answers (574), Thought Type Questions (574), Answers (575), Integer Answer Type Questions (575), Answers (575).

# Elements of Group VIIA or 17 (Halogens, ns2np5)

576 - 624

12.1 Position in Periodic Table (576), 12.2 Anomalous Behaviour of Fluorine (580), 12.3 Fluorine (581), 12.4 Chlorine (582), 12.5 Bromine (586), 12.6 Iodine (588), 12.7 Halogen Acids or Hydracids (591), 12.8 Oxides of Chlorine (595), 12.9 Oxy-Acids of Chlorine (596), 12.10 Interhalogen Compounds (600), 12.11 Polyhalides (601), 12.12 Basic Properties of Iodine (602), 12.13 Pseudohalides and Pseudohalogens (602), Some Solved Problems (602), Summary and Important Points to Remember (605), Practice Problems (608), Answers (611), Illustrations of Objective Questions (613), Objective Questions (615), Answers (620), Objective Questions (622), Answers (622), Thought Type Questions (622), Answers (623), Integer Answer Type Questions (624), Answers (624).

# The Elements of 18 or Zero Group (Inert Gases or Noble Gases, $ns^2np^6$ ) 625 – 644

13.1 Position in the Periodic Table (625), 13.2 Occurrence (627), 13.3 History of the Discovery of Noble Gases (627), 13.4 Isolation of Noble Gases from the Atmosphere (628), 13.5 Separation of Noble Gases (629), 13.6 Uses of Noble Gases (630), 13.7 Compounds of Noble Gases (631), 13.8 Importance of Noble Gases in Theoretical Chemistry (634), 13.9 Determination of Atomic Mass of a Noble Gas (635), Summary and Important Points to Remember (635), Practice Problems (637), Answers (638), Objective Questions (639), Answers (642), Objective Questions for IIT Aspirants (642), Answers (643), Assertion-Reason Type Questions (643), Answers (644), Thought Type Questions (644), Answers (644), Integer Answer Type Questions (644), Answers (644).

### **❖** Revision Exercise-3 (Chapter 8 to 13)

645 - 650

### Transition Elements or *d* - block Elements and *f* - block Elements 651 – 754

14.1 Introduction (651), 14.2 Electronic Configuration (652), 14.3 General Characteristics of Transition Elements (654), 14.4 Chemistry of Chromium (661), 14.5 Potassium Dichromate, K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> (662), 14.6 Chemistry of Manganese (663), 14.7 Potassium Permanganate, KMnO<sub>4</sub> (664), 14.8 Position of Iron in Periodic Table (666), 14.9 Extraction of Iron (667), 14.10 Types of Iron (669), 14.11 Passivity of Iron (672), 14.12 Compounds of Iron (672), 14.13 Corrosion of Iron (674), 14.14 Position of Coinage Metals in Periodic Table (675), 14.15 Copper (678), 14.16 Compounds of Copper (683), 14.17 Silver (687), 14.18 Compounds of Silver (690), 14.19 Gold (692), 14.20 Position of Zinc Family in

Periodic Table (693), 14.21 Zinc (695), 14.22 Compounds of Zinc (697), 14.23 Mercury (699), 14.24 Compounds of Mercury (701), 14.25 Photography (703), 14.26 f-Block Elements (704), 14.27 General Characteristics of Lanthanides (705), 14.28 General Characteristics of Actinides (707), 14.29 Comparison of Lanthanides and Actinides (709), Some Solved Problems (710), Summary and Important Points to Remember (719), Practice Problems (723), Answers (726), Questions Based on the Properties (728), Illustrations of Objective Questions (732), Objective Questions (734), Answers (746), Objective Questions for IIT Aspirants (747), Answers (748), Matrix Matching Questions for IIT Aspirants (749), Answers (749), Assertion-Reason Type Questions (750), Answers (750), Thought Type Questions (750), Answers (752), Brain Storming Problems (753), Integer Answer Type Questions (754), Answers (754).

# Coordination Compounds and Organometallics

755-810

15.1 Molecular or Addition Compounds (755), 15.2 Terminology of Coordination Compounds (756), 15.3 Nomenclature of Coordination Compounds (760), 15.4 Werner's Coordination Theory (762), 15.5 Isomerism in Coordination Compounds (764), 15.6 Bonding in Coordination Compounds (767), 15.7 Stability of Coordination Compounds in Solutions (776), 15.8 Preparation of Coordination Compounds (777), 15.9 Importance of Coordination Compounds (777), 15.10 Organometallic Compounds (780), Some Solved Problems (782), Summary and Important Points to Remember (786), Practice Problems (789), Answers (791), Illustrations of Objective Questions (792), Objective Questions (794), Answers (801), Objective Questions for IIT Aspirants (801), Answers (803), Matrix Matching Questions for IIT Aspirants (804), Answers (804), Assertion-Reason Type Questions (805), Answers (805), Thought Type Questions (806), Answers (807), Brain Storming Problems (807), Integer Answer Type Questions (810), Answers (810).

# Revision Exercise-4 (Chapter 14 to 15)

811 - 815

### Stoichiometry (Calculations Based on Chemical Equations)

816-842

16.1 Introduction (816), 16.2 Calculations Involving Mass-Mass Relationship (816), 16.3 Calculations Involving Mass-Volume Relationship (820), 16.4 Calculations Involving Volume-Volume Relationship (821), Some Miscellaneous Worked Problems (822), Practice Problems (with Hints and Answers) (828), Illustrations of Objective Questions (833), Objective Questions (835), Answers (839), Objective Questions for IIT Aspirants (839), Answers (841), Thought Type Questions (841), Answers (841), Integer Answer Type Questions (842), Answers (842).

### Volumetric Analysis

**843** – 883

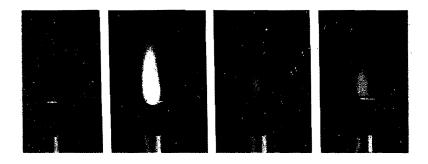

17.1 Introduction (843), 17.2 Methods of Expressing Concentrations of Solutions (844), 17.3 Types of Titrations (845), 17.4 Determination of Equivalent Mass (847), 17.5 Calculations of Volumetric Analysis (849), 17.6 To Determine the Amount of Sodium Hydroxide and Sodium Carbonate in a given Mixture (854), 17.6.1 To Determine the Amount of Sodium Carbonate and Bicarbonate in a Mixture (854), 17.7 Kjeldahl's Process (856), Some Miscellaneous Worked Problems (858), Practice Problems (864), Answers (870), Illustrations of Objective Questions (871), Objective Questions (873), Answers (878), Objective Questions for IIT Aspirants (879), Answers (881), Matrix Matching Questions for IIT Aspirants (881), Answers (881), Assertion-Reason Type Questions (881), Answers (882), Thought Type Questions (882), Answers (883), Integer Answer Type Questions (883), Answers (883).

### Qualitative Inorganic Analysis

884 - 920

18.1 Introduction (884), 18.2 Identification of Acidic Radicals (884), 18.3 Identification of Acidic Radicals with Sodium Carbonate Extract (889), 18.4 Identification of Basic Radicals (890), 18.5 Chemical Reactions Involved in the Tests of Basic Radicals (894), 18.6 Dry Tests (897), Some Solved Problems (899), Practice Problems (904), Answers (908), Illustrations of Objective Questions (909), Objective Questions (910), Answers (915), Objective Questions for IIT Aspirants (916), Answers (917), Matrix Matching Questions for IIT Aspirants (917), Answers (917), Assertion-Reason Type Questions (918), Answers (918), Thought Type Questions (918), Answers (919), Brain Storming Problems (919).

# ♦ Revision Exercise-5 (Chapter 16 to 18)

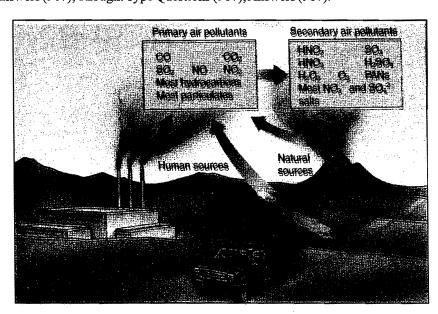

921 - 926

### **Environmental Chemistry**

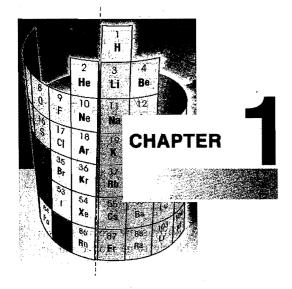

20

927 - 967

19.1 Introduction (927), 19.2 Components of Environment (928), 19.3 Environmental Pollution and Environmental Pollutants (932), 19.4 Some Commonly used terms in Environmental Pollution (933), 19.5 Types of Pollution (933), 19.6 Air Pollution (934), 19.7 Acid Rain (941), 19.8 Smog (944), 19.9 Greenhouse Effect and Global Warming (946), 19.10 Ozone Layer and its Depletion (Stratospheric Pollution) (948), 19.11 Water Pollution (950), 19.12 Soil or Land Pollution (953), 19.13 Strategies to Control Environmental Pollution (955), 19.14 Green Chemistry as an Alternative Tool for Reducing Pollution (956), Some Solved Problems (958), Practice Problems (960), Answers (962), Objective Questions (963), Answers (965), Objective Questions (966), Answers (967), Thought Type Questions (967), Answers (967).

Miscellaneous	968 – 999
Type 1: Short and Very Short Questions	968
Type 2: Matching of Columns	979
Type 3: Multiple Choice—A	981
: Multiple Choice—B	991
Type 4: Assertion-Reason Type	996
Type 5: Thought Type Questions	998
Practice Papers (with Solutions)	1000–1016

# Classification of Elements and Periodicity in Properties

### Contents:

- 1.1 Introduction
- 1.2 Earlier Attempts of Classification of Elements
- 1.3 Mendeleev's Periodic Law and Original Periodic Table
- 1.4 Modern Periodic Law and Modified Form of Mendeleev's Periodic Table
- 1.5 Naming the Elements
- 1.6 Electronic Configurations and the Periodic Table
- 1.7 Extended or Long Form of Periodic Table
- 1.8 Position of an Element on the Basis of Electronic Configuration
- 1.9 Atomic Properties or Periodic Properties of Elements
- 1.10 The Screening Effect or Shielding Effect
- 1.11 Effective Nuclear Charge
- 1.12 Atomic Radius
- 1.13 Ionic Radius
- 1.14 Ionisation Enthalpy or Ionisation Potential
- 1.15 Electron Gain Enthalpy or Electron Affinity
- 1.16 Electronegativity
- 1.17 Some other Properties in which Periodicity is Observed

# 1.1 INTRODUCTION

### Object and Need of Classification of Elements

Elements are the basic constituents of all types of matter. The discovery of chemical elements has been an ongoing process since ancient times. Certain elements, such as gold, appear in nature in elemental form and were thus discovered thousands of years ago. In contrast, some elements are radioactive and intrinsically unstable. The majority of the elements although stable are dispersed widely in nature and incorporated into numerous compounds. For centuries, therefore, scientists were unaware of their existence. At the beginning of the eighteenth century, only a few elements were known. During eighteenth and early nineteenth century, advances in chemistry made it easier to isolate elements from their compounds. As a result, the number of known elements had more than doubled from 31 in 1800 to 63 by 1865. At present, 117 elements\* are known. Out of these, recently discovered elements are not natural but synthetic, *i.e.*, man-made and efforts are still going on to synthesise new elements by artificial transmutation.

As the number of known elements increased, it became rather impossible to study individually the chemistry of these elements and their innumerable compounds and scientists began to investigate the possibilities of classifying them in useful ways. The basic object and need of classification can be best stated in the words of Huxley, "The actual or ideal arrangement together of those which are alike and separation of those which are unlike; the purpose of this arrangement being primarily to disclose the correlations, or laws of union, or properties, or circumstances and secondarily to facilitate the operation

<sup>\*</sup>Recently, elements with atomic numbers 113, 114, 115, 116 and 118 have been reported.

of the mind in clearly receiving and then retaining in the memory the characteristics of the objects in question." In short, it can be stated that the basic object of classification is to arrange the facts regarding elements and their compounds in such a way so that we may have greatest control over their characteristics with least possible effort. The best classification would be one which puts together those elements which resemble in most respects and separates other.

Attempts were made to classify the elements according to one property or the other. The elements were classified into metals and nonmetals; into electropositive and electronegative. They were classed according to their valency as monovalent, divalent, trivalent, etc. In these classifications, the same element frequently appeared in more than one class and hence all these early classifications were considered as rough classifications. After the establishment of Dalton's atomic theory, the chemists took atomic mass as the fundamental property of the element and tried to seek a relationship between the properties of the elements and their atomic masses. A number of classifications, taking atomic masses of the elements as the basis, were presented. The best formulation resulted in the form of periodic table in which elements have been arranged according to their properties in a tabular form. The elements belonging to same vertical column constitute a chemical family having similar properties.

The arrangement of elements in order of increasing atomic masses, with elements having similar properties in vertical columns, is known as periodic table. The periodic classification (long or extended form of periodic table) of elements has extremely simplified the study of such a large number of elements.

# 1.2 EARLIER ATTEMPTS OF CLASSIFICATION OF ELEMENTS (Brief Historical Development of the Periodic Table)

Some of the earlier classifications based on atomic masses of the elements are described below:

#### 1. Döbereiner's Law of Triads

Döbereiner between 1815 and 1829 gave his law of triads. According to which in certain triads (groups of three elements which possessed similar chemical properties) the atomic mass of the central element was merely the arithmetic mean of the atomic masses of the other two elements and the properties of the middle element were in between those of the end members. These families of three elements became known as Döbereiner's Triads. But in some triads, all the three elements possessed nearly the same atomic masses, hence the law was rejected.

#### DÖBEREINER'S TRIADS

7	Triads		Mean of atomic masses of 1st and 3rd elements
Li	Na	K	$\frac{7+39}{2} = 23$
7	23	39	2 - 20
Cl	Br	I	35.5 + 127 - 81.25
35.5	80	127	$\frac{81.25}{2} = 81.25$
Ca	Sr	Ba	$\frac{40 + 137}{2} = 88.5$
40	. 88	137	2 = 88.5
S	Se	Te	32 + 127
32	79	127	$\frac{32}{2} = 79.5$
P	$\mathbf{A}\mathbf{s}$	Sb	$\frac{31+120}{2}=75.5$
31	75	120	<del>2</del> = 75.5
Fe	Co	Ni	Nearly same atomic masses
Ru	Rh	Pd	Nearly same atomic masses
Os	Ir	Pt	Nearly same atomic masses

The main drawback of this classification was that the concept was not applicable to all the known elements but only to a limited number of elements. However, one point became clear that properties of the elements have some relationship with their atomic masses.

# 2. De-Chancourtois Classification (The Telluric Helix)

In 1862, A.E. de Chancourtois a French geologist, made the next attempt to classify the elements on the basis of their atomic masses. He took a vertical cylinder with 16 equidistant lines on the surface of the cylinder. The lines were parallel to the axis of the cylinder. A helix at 45° to the axis was drawn and the elements in the increasing order of their atomic masses were arranged on the helix. He observed that elements which differed from each other in atomic mass 16 or multiples of 16 fell in a vertical line from the centre of the spiral. The elements in a vertical line showed nearly the same properties. However, this classification was not accepted.

#### 3. Newland's Law of Octaves

The first attempt to classify all the known elements was made by Newland in 1864. He presented the law of octaves. According to this law, the elements when arranged in order of their increasing atomic masses, the eighth succeeding element was the repetition of the first one like 8th note of the musical scale, i.e., after a difference of seven, elements with similar characteristics were observed. The following are the three horizontal rows of the Newland's classification:

Musical	scale:	Sa.	Re	Ga	Ma	- Pa	Dha	- Ne
		1	.2	3	4	5	6	7
	1st	H	Li	Be	В	$\mathbf{C}_{\perp}$	N.	. 0
*	2nd	F	Na	Mg	Al	Si .	P	S
	3rd	Cl	K	Ca	Cr	Ti	Mn	Fe

The system worked quite well for the lighter elements. For example, H, F and Cl show similar properties and similarly

Li, Na and K exhibit same characteristics. The system, however, fails in the case of heavier elements as manganese has been placed along with nitrogen and phosphorus or iron has been placed along with oxygen and sulphur, i.e., dissimilar elements have been grouped which is against the aim of classification. This clearly shows that in the classification, the properties of the elements were not taken into account and only the elements were arranged in order of ascending atomic masses. No space was left for the elements which were unknown at that time and many elements were provided wrong positions on account of wrong values of atomic masses in this classification. Thus, Newland's classification was not accepted as an appropriate arrangement. However, his work was recognised by Royal Chemical Society, London, and was awarded Davy Medal in 1887.

### 4. Lother Meyer's Curve

Lother Meyer in Germany and Mendeleev in Russia quite independently evolved, in 1869, identical classifications of elements. Both these classifications emphasised the periodicity of the properties of the elements with their atomic masses. While Mendeleev's classification was based largely on considerations of chemical properties of the elements, that of Lother Meyer emphasised physical characteristics of the elements. Lother Meyer presented the classification in the form of curve while Mendeleev in the form of a table.

Lother Meyer calculated the atomic volumes of the known elements by applying formula,

Atomic volume = 
$$\frac{\text{Atomic mass}}{\text{Density}}$$

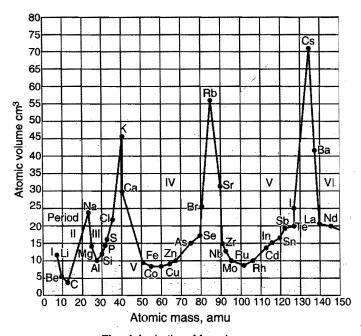

Fig. 1.1 Lother Meyer's curve

When he plotted these atomic volumes against corresponding atomic masses, a curve taking the form of sharp peaks and broad minima was obtained (Fig. 1.1).

Lother Meyer pointed out that elements having similar properties occupy similar positions on the curve such as,

- (i) Alkali metals, having the largest atomic volumes, occupy the maxima of the curve.
- (ii) The alkaline earth metals (Mg, Ca, Sr, Ba) occupy positions at about the mid-points on the descending portions of the curve.
- (iii) The halogens (F, Cl, Br, I) occupy positions on the ascending portions of the curve.
- (iv) The transition elements occupy minima of the curve. On the basis of above observations Lother Meyer proposed that, the physical properties of the elements are a periodic function of their atomic masses.

[Later on when atomic numbers of the elements were plotted in place of atomic masses, the general pattern of the curve remained the same.]

It was an ideal classification but lacked in practical utility as it was not easy to keep in mind the various portions of the curve.

# 1.3 MENDELEEV'S PERIODIC LAW AND ORIGINAL PERIODIC TABLE

Mendeleev put forward the periodic law which forms the basis of modern classification of elements in the form of a table, known as the periodic table. The periodic law can be stated as, "If the elements are arranged in order of increasing atomic masses, their properties vary in definite manner from member to member of the series, but return more or less nearly to same value at certain fixed points in the series". In other words the properties of the elements are a periodic function of their atomic masses. This was an impressive version of law of octaves. The main points of periodic law as stated by Mendeleev in his original paper are reproduced below:

- 1. The elements, if arranged according to their atomic weights exhibit an evident periodicity of properties.
- **2.** Elements which are similar as regards their chemical properties have atomic weights which either are of nearly same value, *e.g.*, Fe, Co, Ni or increase regularly, *e.g.*, K, Rb, Cs.
- 3. The arrangement of elements or groups of elements in the order of their atomic weights corresponds to their so called "valencies" as well as their distinctive properties.
- 4. The elements which are most widely distributed in nature have small atomic weights and possess sharply defined properties.
- 5. The magnitude of atomic weight determines the character of the element.
  - 6. Many yet unknown elements may be discovered.
- 7. The atomic weight of an element may sometimes be corrected with the aid of the knowledge of the atomic weights of the adjacent elements.

**8.** Certain characteristic properties of elements can be foretold from their atomic weights.

Mendeleev's original table prepared in the light of the above statements arranged similar elements in horizontal rows but subsequently he modified the original table arranging similar elements in vertical columns. The original modified periodic table, is shown in Fig. 1.2.

A tabular arrangement of elements in rows and columns, highlighting the regular repetition of properties of elements is called a periodic table.

Mendeleev arranged the elements between hydrogen and uranium, providing 90 spaces between these two elements, in order of increasing atomic masses. Elements with similar properties were present in vertical columns called **groups**. The horizontal rows were called **periods**. Mendeleev violated his periodic law at certain places to give appropriate position to the few elements on the basis of their

properties, *i.e.*, he laid emphasis on the properties of the elements rather than their atomic masses. For example, iodine having lower atomic mass than tellurium was placed ahead of tellurium because iodine showed similarities with fluorine, chlorine and bromine.

When Mendeleev presented the periodic table, only 63 elements were known. Thus, a number of gaps for unknown elements were left in the table and the properties of these unknown elements were predicted on the basis of periodic law. These predicted properties helped the future scientists in the discovery of unknown elements. For example, gallium and germanium were not known when Mendeleev presented the periodic table. These elements were named eka-aluminium and eka-silicon. Their properties were predicted by Mendeleev and these properties actually matched the properties of elements when discovered.

Mendeleev's	Original	Periodic	Table of	Elements
-------------	----------	----------	----------	----------

Series	Gṛoup I R₂O	Group II RO	Group III R <sub>2</sub> O <sub>3</sub>	Group IV RO <sub>2</sub> /RH <sub>4</sub>	Group V RH <sub>3</sub> /R <sub>2</sub> O <sub>5</sub>	Group VI RH <sub>2</sub> /RO <sub>3</sub>	Group VII RH/R <sub>2</sub> O <sub>7</sub>	Group VIII RO <sub>4</sub>

9.							_	
10.			*Er = 178	*La = 180	Ta = 182	W = 184		Os = 195, Ir = 19 Pt = 198
11.	(Au = 199)	Hg = 200	T1 = 204	Pb = 207	Bi = 208			
12.	-			Th = 231		U = 240		

Fig. 1.2 Mendeleev's Periodic Table (Published in 1872)

The table given below gives a comparative idea about the predicted and actually observed some of the properties of these elements.

Property	Eka-aluminium (Predicted)			Germanium (Observed)
Atomic mass	68	70	72	72.6
Density (g/cm <sup>3</sup> )	5.9	5.94	5.5	5.36
Formula of oxide	E <sub>2</sub> O <sub>3</sub>	Ga <sub>2</sub> O <sub>3</sub>	EO <sub>2</sub>	GeO <sub>2</sub>
Formula of chloride	ECl <sub>3</sub>	GaCl <sub>3</sub>	ECl <sub>4</sub>	GeCl <sub>4</sub>

Atomic weight is now referred as atomic mass.

The original periodic table consisted eight vertical columns called **groups** (Fig. 1.2). Each group consisted elements having similar properties, especially the same valency. This table consisted a number of defects such as anomalous pairs, position of isotopes, position of lanthanides and actinides, etc. Some of these defects do not exist in modern Mendeleev periodic table.

# 1.4 MODERN PERIODIC LAW AND MODIFIED FORM OF MENDELEEV'S PERIODIC TABLE

As the physical and chemical properties of an element depend on the number of electrons and their arrangement in various energy shells of the atom, the atomic number (the number of positive charges on the nucleus or number of electrons in energy shells) is thus the fundamental property of the element. The change in atomic number always changes the fate of the element, *i.e.*, a new element comes into existence. **Moseley**, thus, suggested that basis of classification of elements should be the **atomic numbers** of the elements rather than the **atomic masses** of the elements. He

modified the periodic law by saying that physical and chemical properties of the elements are periodic function of their atomic numbers. When the elements are arranged in order of their increasing atomic numbers, the same table as presented by Mendeleev, is obtained. The table based on atomic numbers of the elements is called modern Mendeleev's periodic table (Fig. 1.3). In modern periodic table, similar properties recur after the intervals of 2, 8, 8, 18,

Fig. 1.3 Modern Mendeleev's Periodic Table

18 and 32 elements, *i.e.*, if the elements are arranged in the increasing atomic numbers, the properties of the elements reappear after definite regular intervals. With the replacement of atomic mass by atomic number as the basis of classification, two main defects of original table based on atomic masses disappear. These defects are:

(i) Anomalous pairs: The original periodic law based on atomic masses is violated in case of four pairs of elements in order to give them positions on the basis of properties. The elements having higher atomic masses have been assigned positions before the elements having lower atomic masses at four places as shown below:

This defect disappears, if the elements are arranged in order of increasing atomic numbers.

(ii) Position of isotopes: Isotopes are atoms of the same element having different atomic masses but same atomic number. The isotopes of the same element will be given different positions, if atomic mass is taken as a basis. This shall disturb the symmetry of the table. In modern table, one position is fixed for one atomic number and since all the isotopes of an element have the same atomic number, these are assigned only one position.

### **■** Description of the Modern Periodic Table

The main characteristics of the modern periodic table are,

- (i) The modern periodic table consists of nine vertical columns called 'groups' and seven horizontal rows called 'periods'. The nine groups are marked from 0 to VIII. The groups I to VII are divided each into subgroups A and B. The groups I to VII are termed normal groups. In the VIII group in one place, there are three similar elements placed together which are known as transition triads—Fe, Co and Ni; Ru, Rh and Pd; Os, Ir and Pt; Hs(Uno), Mt (Une) and Uun.
- (ii) Starting from hydrogen to the heaviest element, uranium, there are 92 elements which are arranged in different periods as follows:

_		
First period	2 elements	(very short period)
Second period	8 elements	(short period)
Third period	8 elements	(short period)
Fourth period	18 elements	(long period)
Fifth period	18 elements	(long period)
Sixth period	32 elements	(very long period)
Seventh period	6 elements upto	(very long period, incom-
	at. no. 92	plete period)

The IV, V and VI periods possess two horizontal rows each, which are termed even and odd series. In the 6th period, fifteen elements from lanthanum (At. no. 57) to lutetium (At. no. 71) are given only one position in third group. These

elements are known as rare-earths or lanthanides (from At. no. 58 to 71) and are separately arranged below the table in a horizontal row.

The last period consists of 28 elements, out of which 14 elements from atomic number 90 to 103 are separately arranged like lanthanides below the table in a horizontal row. These elements are called **actinides**.

(iii) Every period starts from a member of alkali group and ends with a member of zero group. The first period, however, starts with hydrogen.

Period	Ist element/ At. no.		ement/ no.		elements period
1st period	H-(1)	. I	He (2)		2
2nd period	Li (3) $\right\}^2$	N	e (10)		8
3rd period	Na (11) $\}^8$	A 8	ır (18)		8
4th period	K (19)	•	(36)		18
5th period	Rb(37)	x را	(e (54)		18
6th period	Cs(55)	,	Rn(86)	•	32
7th period	Fr(87)	}32 Uud	o(118)		nplete I today

The difference in the atomic numbers of subsequent alkali metals indicates that similar properties recur after the intervals of 2, 8, 8, 18, 18 and 32.

(iv) There is a gradual change in properties of the elements, when we move in a period from one end to the other end. Some examples are given below to justify this gradual change.

(a) Valency: Valency of the elements increases from 1 to 7 from left to right if oxygen is taken as standard. The valency of the elements with respect to hydrogen increases from 1 to 4 and then decreases from 4 to 1 in a period.

Group	I	II	III	IV	V	VI	VII
Valency with respect to oxygen	1	2	3	4	5	6	7
Formula of the oxide	$R_2O$	RO	$R_2O_3$	$RO_2$	$R_2O_5$	$RO_3$	$R_2O_7$
Valency with respect to hydrogen	1	2	3	4	3	2	1
Formula of the hydride	e RH	RH <sub>2</sub>	$RH_3$	$RH_4$	$RH_3$	$RH_2$	RH

This trend is observed in every period. Considering the members of third period,

Thus, group number signifies the valency of the elements belonging to that group if oxygen is taken as a standard. **(b) Metallic nature:** In a period from left to right metallic nature decreases while non-metallic character increases.

3rd period Na Mg Al Si P S Cl

Metals Metalloid Non-metals

Non-metallic nature in increasing order

Metallic nature in decreasing order

(c) Electropositive / Electronegative character: The electropositive character decreases in a period from left to right or electronegative character increases.

2nd period Li Be B C N O F

Electronegative nature in increasing order

or

Electropositive nature in decreasing order

(d) Oxidising and reducing nature: In a period, from left to right, the reducing nature decreases while oxidising nature increases.

3rd period Na Mg Al Si P S Cl
Strong reducing agents Strong oxidising agents

**(e)** Nature of oxides: In a period, from left to right the basic nature of the oxides decreases while acidic nature of the oxides increases.

 $Na_2O$  is more basic than MgO and MgO is more basic than  $Al_2O_3$ .

**(v) Typical elements:** The elements of second and third periods are called **typical elements** as they summarise the properties of their respective groups.

 Groups
 I
 II
 III
 IV
 V
 VI
 VII

 2nd period
 Li
 Be
 B
 C
 N
 O
 F

 3rd period
 Na
 Mg
 Al
 Si
 P
 S
 Cl

Li and Na are typical elements of 1st group while Be and Mg are typical elements of 2nd group and so on.

(vi) Bridge elements: The typical elements of third period are also called bridge elements as the division between two subgroups A and B starts from these elements. In second group, Mg acts as a bridge element. The properties of bridge element are somewhat mixed properties of the elements of two subgroups as magnesium shows similarities with alkaline earth metals (IIA) on one hand and with zinc metals (IIB) on the other.

(vii) Diagonal relationship: The first three members of second period (Li, Be and B) not only show similarities with the members of their own groups but show similarities with the elements diagonally placed in the higher groups. This resemblance is termed diagonal relationship.

Lithium shows similarities with magnesium, beryllium with aluminium and boron with silicon.

(viii) The elements belonging to the same subgroup exhibit either same properties or a regular gradation in properties from top to bottom. Some examples are given below:

- (a) In the case of elements of IA group (Li, Na, K, Rb, Cs), the electropositive character or reactivity increases as the atomic number increases. All the members show monovalency and are never found in free state. The oxides are basic and form strong alkalies.
- (b) In IVA group, the metallic character increases gradually:

The acidic nature of the oxides decreases from top to bottom. CO<sub>2</sub> is acidic while PbO<sub>2</sub> is basic in nature.

(c) In VIIA group, the reactivity of the halogens decreases from top to bottom. These are electronegative and this nature decreases from top to bottom. Their hydrides are acidic in nature and acidic nature increases as the atomic number increases.

(ix) The elements of the same subgroup resemble, quite closely to each other but there is hardly any resemblance between the elements of two subgroups A and B. For example, in the first group, the subgroup A consists of alkali metals

(Li, Na, K, Rb, Cs) and subgroup B consists of **coinage metals** (Cu, Ag, Au) but there appears hardly any resemblance between the members of these two subgroups except all show monovalency. Some properties are given below to justify this statement:

IA (alkali metals)
(Li, Na, K, Rb, Cs)
(Cu, Ag, Au)

(i) Soft metals
(ii) Low densities
(iii) Low melting points
(iv) Highly reactive
(v) Never found free in
nature

IB (coinage metals)
(Cu, Ag, Au)

(ii) Hard metals
(iii) High densities
(iii) High melting points
(iv) Less reactive, noble metals
(v) Found mainly free in nature

(vi) Decompose water readily

(vi) Do not decompose water

The difference in properties of two subgroups is maximum in the first group and decreases from first to fourth group. The difference again becomes maximum in the seventh group.

### Applications or Advantages of the Modern Periodic Table

- (i) Classification of elements: There is no doubt that the Mendeleev's periodic system is far superior to the all earlier classifications of elements. The periodic table has reduced the study of 117 known elements into the study of few groups. If we know the properties of a single member of a group, we can have good approximation of the properties of other members of this group without individually studying them.
- (ii) Discovery of new elements: A number of gaps were left in Mendeleev's periodic table for unknown elements. Mendeleev even predicted the properties of these unknown elements. These properties helped the workers to discover the unknown elements more readily and accurately. Thus, the periodic system hastened the discovery of many new elements. In modern periodic table, no gap is present, *i.e.*, all the unknown elements upto 112 have been discovered. Recently, the elements with atomic numbers 113 to 116 and 118 have been reported. Element with atomic number 117 is still to be discovered to complete the last, *i.e.*, 7th period of the periodic table.
- (iii) Correction of atomic mass: Atomic mass of an element is related with equivalent mass of the element by the following formula:

Atomic mass = Equivalent mass × valency

Valency of the element can be known from its position in the periodic table. This formula was utilised in the correction of atomic mass of many elements. For example, when Mendeleev presented the periodic table, the atomic mass of beryllium was not correctly known. However, its equivalent mass was known to be 4.55. It was thought that the element possessed valency 3 as its oxide was isomorphous with alumina ( $Al_2O_3$ ). Thus, the atomic mass of this element came out to be  $3 \times 4.55 = 13.65$ . On the basis of this value of atomic mass, it should have been given position after carbon (At. wt. 12) but Mendeleev assigned position to beryllium in second group, *i.e.*, he considered beryllium as bivalent. The atomic mass of beryllium was given the value  $4.55 \times 2 = 9.10$ . This value of atomic mass justified its position in second group along with Mg, Ca, Sr, etc. In the modern periodic table the atomic masses of all the elements have been corrected.

Thus, the (ii) and (iii) points are of only historical importance because all the unknown elements have already been discovered and the atomic masses of the elements have already been corrected.

#### **■** Defects of Modern Periodic Table

Inspite of its great usefulness in the study of various elements, the modern periodic table suffers from the following defects:

- (i) Position of hydrogen: On account of the dual nature of hydrogen as it shows resemblance with alkali metals and also with halogens, its position in periodic table is uncertain. It is sometimes placed in the first group and sometimes in the seventh group. However, the symmetry of the periodic table is not disturbed whether it is accommodated in the first group or in seventh group. It is, therefore, difficult even at present, to decide to where it should correctly be placed.
- (ii) Similar elements separated: Certain elements which show similar properties have been separated in the periodic table. For example, Ba and Pb resemble each other in so many respects but have been placed in second and fourth groups, respectively. Similarly Ag and Tl having similar properties have been separated, Ag placed in the first group and Tl in the third group.
- (iii) Dissimilar elements placed together in the same group: Elements showing marked dissimilarities are placed in one group. For example, coinage metals (Cu, Ag and Au) have been placed with alkali metals in the first group. Manganese has been placed in seventh group along with halogens with which it shows little resemblance.
- (iv) Metals and nonmetals: No attempt has been made to place metals and nonmetals separately in the periodic table. Most of the groups are mixed groups consisting of metals, nonmetals and metalloids.
- (v) Position of VIII group: There are twelve elements in this group and they are accommodated in only four available positions. This group is present between seventh and zero groups which is not justified.
- (vi) Positions of transition elements: Mendeleev regarded only the three triads of VIII group as the only

transition elements but modern studies have confirmed that there are 40 (upto At. no. 112) transition elements. These similar elements are scattered in whole of the periodic table. These elements are present in every group except zero group.

(vii) Position of lanthanides and actinides: Inspite of the fact that members of lanthanide series and actinide series have different atomic numbers, these have not been given individual places in the periodic table. The 14 members of lanthanide series have been placed along with lanthanum in the third group and sixth period and similarly 14 members of the actinide series have been placed along with actinium in third group and seventh period. The justification for assigning one place to these elements has been given on the basis of their similar properties. The properties are so similar that the fifteen elements from La to Lu can be considered as equivalent to one element. In case, these elements are assigned different positions, i.e., arranged in order of their increasing atomic numbers, the symmetry of the whole arrangement would be disrupted. The same explanation can be given in the case of actinides.

# 1.5 NAMING THE ELEMENTS

Every element has been given a definite name and for covenience a nick name which in chemical language is called a **symbol**. When a new element is discovered, the discoverer usually gets the opportunity to suggest a name for the element, which is then approved by **The International Union of Pure and Applied Chemistry-IUPAC**.

Symbols have been derived either by taking the first alphabet of the name of the element or by taking the first alphabet and one more alphabet from the name of the element (for example, C for carbon; N for nitrogen; O for oxygen; Ca for calcium; Al for aluminium, etc.) but there are quite number of elements for which the derivation of the symbol is not quite so obvious: for example, Na for sodium; Pb for lead; Ag for silver; Fe for iron, etc. Such anomalies occur because of the way, the elements were originally named. Some of the elements were given names in other languages such as Latin, German, etc.

Of all the elements on the periodic table, C,S, Fe, Cu, As, Ag, Sn, Sb, Au, Hg, Pb and Bi were known to ancient civilisations so the date of their 'discovery' is not known. Of these, Fe, Cu,

#### SCIENTIST/PERSONS AFTER WHOM ELEMENTS HAVE BEEN NAMED

Name	Brief biography	Element named
Vasilii Yefrafovich von     Samarski-Bykhovets (1803-1870)	Chief of staff of the Russian Corps of Mining Engineers	samarium, Sm (element 62)
2. Johan Gadolin (1760-1852)	Finnish chemist; first person to isolate a lanthanide element	gadolinium, Gd (element 64)
3. Pierre Curie (1859-1906) and Marie Curie (1867-1934)	Husband and wife scientific team; Pierre French and Marie Polish by birth; jointly won the Nobel Prize in physics in 1903	curium, Cm (element 96)
4. Albert Einstein (1879-1955)	Most famous scientist of the twentieth century; German by birth; won the Nobel Prize in physics in 1921	einsteinium, Es (element 99)
5. Enrico Fermi (1901-1954)	Italian physicist; made great advances in the study of nuclear reactions; won the Nobel Prize in physics in 1938	fermium, Fm (element 100)
6. Dmitri Mendeleev (1834-1907)	Russian chemist; renowned for the development of the periodic table	mendelevium, Md (element 101)
7. Alfred Nobel (1833-1896)	Swedish inventor of dynamite an patron of the Nobel Prizes	nobelium, No (element 102)
8. Ernest Lawrence (1901-1958)	American inventor of the cyclotron; won the Nobel Prize in physics in 1939	lawrencium, Lr (element 103)
9. Ernest Rutherford (1871-1937)	New Zealand physicist/chemist; made seminal contributions to understanding the structure of the atom; won the Nobel Prize in chemistry in 1908	rutherfordium, Rf (element 104)
10. Glenn Seaborg (1912-1999)	American chemist; first prepared many of the elements beyond uranium in the periodic table; won the Nobel Prize in chemistry in 1951	seaborgium, Sg (element 106)
11. Niels Bohr (1885-1962)	Danish physicist; studied electronic energy levels within atoms, which help our understanding of the atom; won the Nobel Prize in physics in 1922	bohrium, Bh (element 107)
12. Lise Meitner (1878-1968)	Austrian physicist; made discoveries concerning nuclear fission; controversially never awarded a Nobel Prize	meitnerium, Mt (element 109)
13. Wilhelm Röntgen (1845-1923)	German physicist; discoverer of X-rays; won the Nobel Prize in physics in 1901	röntgenium, Rg (element 111)

Ag, Sn, Sb, Au, Hg and Pb are the abbreviations for the Latin names ferrum, cuprum, argentum, stannum, stibium, aurum, hydragyrum and plumbum. The earliest known discovery of an element was that of phosphorus, P. It was isolated in 1669 by Hennig Brand from the distillation of urine (he was apparently trying to make silver or gold—unsuccessfully, of course!) and was named after the Greek word phosphoros, meaning 'bringer of light', as the element glows in the dark. Elements have been named after countries (germanium, francium, americium, polonium) and even after the places they were first discovered; the Swedish town of Ytterby has the distinction of having four elements (erbium, Er; ytterbium, Yb; yttrium, Y; and terbium, Tb) named after it, as these were found in deposits close to the town. Surprisingly few elements have been named after people; at present, only 14 people have been immortalised on the periodic table, and they are listed in table given on page 9.

# ■ Nomenclature of Elements with Atomic Numbers > 100

The elements coming after uranium which do not exist naturally, are named transuranic or transuranium elements. The elements with Z = 104 - 116 and 118 have been reported recently and are called transactinides or super-heavy elements. These are synthetic, i.e., man-made elements. The production of synthetic elements requires binuclear reactions between two positive nuclei that must be fused together against the force of electrical repulsion. Nuclear accelerators are used for this purpose. There are currently two major groups working on producing super-heavy elements, one in California, USA and the other at Dubna near Moscow, Russia. By convention, the workers who discover a new element have the right to name it. However, in recent years, on account of competitive spirit disputes have arisen over the names of the newly discovered elements. For example, both American and Russian scientists claimed credit for the discovery of the element 104. The Americans named it Rutherfordium whereas Russians named it Kurchatovium. To avoid such problems, the IUPAC suggested that until the discovery of the new element is proved and its name is officially recognised, a systematic nomenclature based on the atomic number of the element be followed. The following are the points of the nomenclature of the element having atomic

1. The names are derived by using the numerical roots for three digits in the atomic number of the element and adding the ending -ium. The roots for the numbers are:

Digit	Name	Abbreviation
0	nil	<b>n</b>
		$oldsymbol{u}_{i,j}$
2	bi	b
3	tri	
4	quad	
5		<b>p</b>
6		grand holder between
	sept	and the state of t
		tax aro, txt. to a
s, it ,	enn	. Units e who we

- 2. In certain cases the names are shortened. For example, 'biium' and 'triium' are shortened to 'bium' and 'trium' and 'ennnil' is shortened to 'ennil'.
- 3. The symbol for the element is made up from the first letters from the roots which make up the names. The mixture of Latin and Greek roots has been chosen to ensure that the symbols are all different.

**IUPAC Nomenclature for the Super Heavy-Elements** 

Atomic number	Name of t	the element	Symbol
101	Unnilunium	$\frac{\underline{Un} - \underline{nil} - \underline{un} - ium}{1}$	(Unu)
102	Unnilbium	$\frac{\operatorname{Un}}{1} - \frac{\operatorname{nil}}{0} - \frac{\operatorname{bi}}{2} - \operatorname{um}$	(Unb)
103		$\frac{Un}{1} - \frac{nil}{0} - \frac{tri}{3} - um$	(Unt)
104	Unnilquadium	$\frac{\operatorname{Un} - \operatorname{nil}}{1} - \frac{\operatorname{quad}}{0} - \operatorname{ium}$	(Unq)
105	Unnilpentium	* *	(Unp)
106	Unnilhexium		(Unh)
107	Unnilseptium		(Uns)
108	Unniloctium		(Uno)
109	Unnilennium		(Une)
110	Ununnilium		(Uun)
111	Unununium	$\frac{Un}{1} - \frac{un}{1} - \frac{nu}{1} - ium$	(Uuu)
112	Ununbium	$\frac{Un}{1} - \frac{un}{1} - \frac{bi}{2} - um$	(Uub)
113	Ununtrium	$\frac{Un}{1} - \frac{un}{1} - \frac{tri}{3} - um$	(Uut)
114	Ununquadium	$\frac{Un}{1} - \frac{un}{1} - \frac{quad}{4} - ium$	(Uuq)
115	Ununpentium	$\frac{Un}{1} - \frac{un}{1} - \frac{pent}{5} - ium$	(Uup)
116	Ununhexium	$\frac{\text{Un}}{1} - \frac{\text{un}}{1} - \frac{\text{hex}}{6} - \text{ium}$	(Uuh)
118	Ununoctium	$\frac{\text{Un}}{1} - \frac{\text{un}}{1} - \frac{\text{oct}}{8} - \text{ium}$	(Uuo)
120	Unbinilium	$\frac{U\mathbf{n}}{1} - \frac{\mathbf{bi}}{2} - \frac{\mathbf{nil}}{0} - \mathbf{ium}$	(Ubn)

At present 117 elements have been discovered. These are the elements with atomic numbers upto 116 and 118. Element

with atomic number 117 is yet to be discovered. Official IUPAC names for the elements upto 111 have been approved by the Commission on Nomenclature of Inorganic Chemistry (CNIC).

Thus, the newly discovered element is first given a temporary name on the basis of atomic number and later on a permanent name with symbol is alloted by the consent of IUPAC representatives.

### Nomenclature of Elements with Atomic Number above 100

Atomic number	Name on the basis of atomic number (Temporary)	Official IUPAC name (Permanent)	Symbol
101	Unnilunium	Mendelevium	Md
102	Unnilbium	Nobelium	No
103	Unniltrium	Lawrencium	Lr
104	Unnilquadium	Rutherfordium	Rf
105	Unnilpentium	Dubnium	Db
106	Unnilhexium	Seaborgium	Sg
107	Unnilseptium	Bohrium	Bh
108	Unniloctium	Hassium	Hs
109	Unnilennium	Meitnerium	Mt
110	Ununnilium	Darmstadtium	Ds
111	Unununium	Rontgenium	Rg
112	Ununbium*		
113	Ununtrium*		_
114	Ununquadium*		
115	Ununpentium*		
116	Ununhexium*		
118	Ununoctium*		

<sup>\*</sup>Official IUPAC name yet to be announced.

# 1.6 ELECTRONIC CONFIGURATIONS AND THE PERIODIC TABLE

The aufbau principle and electronic configuration of the atoms of elements provide a theoretical foundation for the classification of elements. It is now recognised that the periodic table is essentially the consequence of the periodic variation in electronic configuration of the atoms of the elements which determine the physical and chemical properties of the elements and their compounds. The elements in a vertical column, i.e., in a group of the periodic table exhibit similar chemical behaviour. This is due to the fact that these elements have same number and same distribution of electrons in their outermost orbitals, i.e., in the valency shell. For example, the group IA elements (alkali metals) which show same chemical behaviour possess same valence shell configuration, i.e., ns<sup>1</sup>. Similarly, the group VIIA elements (halogens) which are similar in chemical properties possess same valence shell configuration, ns<sup>2</sup>np<sup>5</sup>.

In the periodic table, the elements have been arranged in order of increasing atomic number, *i.e.*, increased number of orbital electrons. Thus, each element contains one more orbital electron than the preceding element. Each period starts with  $ns^1$  configuration and ends with a noble gas (He,  $1s^2$ , in the first period and  $ns^2np^6$  configuration with rest of the elements). The sequence in which the various energy levels are filled determines the number of elements.

1st period	1s		M pr	2 elements in this period
2nd period	2s		2p	8 elements in this period
3rd period	3s		3p	8 elements in this period
4th period	<b>4</b> s	3 d	4 p	18 elements in this period
5th period	5s	4 <i>d</i>	5 <i>p</i>	18 elements in this period
6th period	6s 4	f 5d	6p .	32 elements in this period
7th period	7s. 5	f 6d	7 p	32 elements in this period

The ground state electronic configurations of the elements are given in the following table. For the sake of simplicity, condensed electronic configurations of the elements are given. In writing condensed electronic configuration of an element, the electronic configuration of the nearest noble gas of lower atomic number is represented by its chemical symbol in square bracket. For example, the condensed electronic configuration of sodium can be written as:

 $\label{eq:Nellows} \mbox{[Ne] } 3s^1$  Electronic Structures of the Elements

Z	Element	Symbol	Structure
		Period – 1	
1	Hydrogen	Н	$1s^1$

# Classification of Elements on the Basis of Electronic Configurations

### 1. Bohr's Classification

The classification proposed by Bohr is based on complete and incomplete energy shells. The elements have been grouped into four types:

(i) Inert gases: In the atoms of these elements, the s-and p-subshells of the outermost shell are completely filled.

With the exception of helium which has  $1s^2$  configuration, all other have  $ns^2np^6$  configuration. Because of stable configuration, these elements do not show chemical activity under normal conditions. These are all gases under normal conditions and thus, termed as inert gases. Under special conditions, the higher members do form some compounds with other elements and hence, the name has been changed to **noble gases**. Seven elements He, Ne, Ar, Kr, Xe, Rn and Uuo belong to this group. This group was unknown at the time when Mendeleev presented the periodic table. These elements are the end members of the respective periods of the periodic table, respectively.

(ii) Representative or Normal elements: In these elements atoms have all shells complete except outermost shell which is incomplete. The number of electrons in the outermost shell varies from 1 to 7, i.e., the configuration of the outermost shell varies from  $ns^1$  to  $ns^2$   $np^5$ . These elements comprise of some metals, all non-metals and metalloids. These are the elements which are found in nature in abundance and active in nature. On account of this, these elements are called **representative elements**. All the three types of valencies are observed in the case of these elements. These elements have one of the following configurations in their outermost shell:

$$ns^{1}$$
,  $ns^{2}$ ,  $ns^{2} np^{1}$ ,  $ns^{2} np^{2}$ ,  $ns^{2} np^{3}$ ,  $ns^{2} np^{4}$ ,  $ns^{2} np^{5}$   
1 2 3 4 5 6 7

The number of electrons present in the outermost shell signify the group to which these elements belong.

(iii) Transition elements: In the atoms of these elements the outermost shell and the penultimate shell (next to the outermost) are incomplete. These elements have the general configuration  $(n-1)d^{1-9} ns^{0 \text{ or } 1 \text{ or } 2}$  either in the ground state or in excited state. These elements are present in fourth, fifth, sixth and seventh periods of periodic table and are called transition elements. The elements showing horizontal relationship as well as vertical relationship are termed transition elements. There are four transition series, every series consists of 9 elements each. Each series starts with a member of third group and ends with a member of first group.

```
1st series Sc 21 to Cu 29 3d^{1-9}4s^2

2nd series Y 39 to Ag 47 4d^{1-9}5s^2

3rd series La 57 to Au 79 5d^{1-9}6s^2

[The elements from Ce (58) to Lu (71) are not included]

4th series Ac 89, Rf (104), Db (105)

and 106 to 111 [The elements from Th (90) to Lr (103) are not included]
```

The elements belonging to this group are all metals.

- (iv) Inner-transition elements: Atoms of these elements have three outermost shells incomplete. The general configuration is  $(n-2)f^{1-14}(n-1)d^{0 \text{ or } 1} ns^2$ . There are two series of elements,
  - (a) Lanthanides or rare-earths from Ce (58) to Lu (71)
  - (b) Actinides from Th (90) to Lr (103).

Each series consists of 14 elements, *i.e.*, in the lanthanides, 4f is gradually filled up while in actinides, 5f is gradually filled up. The properties of these elements are similar to transition elements. The members of actinide series are radioactive and majority of them are not found in nature. The elements from atomic number 93 onwards are called transuranic elements and have been discovered by artificial means.

In this classification, the elements Zn, Cd and Hg have not been included in any of the four groups of elements. The elements Lu and Lr of the inner-transition group have (n-2)f shell complete consisting of 14 electrons, hence their inclusion in this group is not justified.

### 2. Differentiating Electron Classifications

(Division of elements into s-, p-, d-, f-Blocks)

This classification divides the elements into four types, *i.e.*, *s*-, *p*-, *d*- and *f*-block elements depending on the nature of the atomic shell into which the last electron enters. The last electron is called as **differentiating electron**. This classification is most rational and is now commonly in use. The energy shell into which the last electron enters is of highest energy. This may not always belong to the outermost energy shell. In general, it can be said that aufbau principle is followed in filling of various energy shells with few exceptions.

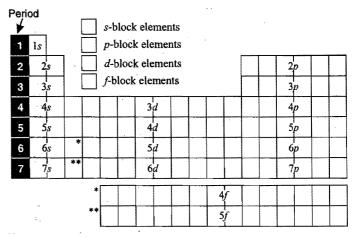

Fig. 1.4 Periodic table, illustrating division of elements into s-, p-, d-, f- Blocks

### ■ (i) s-Block Elements

In these elements, the last electron enters the ns energy shell. The maximum capacity of ns energy shell is of two electrons, thus, these elements have valency shell configuration either  $ns^1$  or  $ns^2$ .

The members of this block lie on the extreme left of the periodic table. The elements having  $ns^1$  configuration are called **alkali metals** (Group IA elements) while those having  $ns^2$  configuration are called **alkaline earth metals** (Group IIA elements). The elements of s-block are also called as **Reactive metals**.

#### General Characteristics of s-Block Elements:

The general characteristics of alkali metals (Li, Na, K, Rb, Cs and Fr) and alkaline earth metals (Be, Mg, Ca, Sr, Ba and Ra), i.e., s-block elements are the following:

- (i) They are soft metals, possess low melting and boiling points, have the largest atomic radii in their corresponding periods and are good conductors of heat and electricity.
- (ii) They have low values of ionisation energies and hence highly electropositive.
- (iii) They are very reactive and readily form ionic compounds. They show a fixed valency which depends on the number of electrons present in the outermost shell. The alkali metals show monovalency while alkaline earth metals show divalency. They are never found in free state in nature due to their reactive nature.
- (iv) On account of low ionisation energies and highly negative electrode potentials, they act as strong reducing agents. The alkali and alkaline earth metals cannot be prepared by doing electrolysis of aqueous solutions of their salts.
- (v) Except Be and Mg, they impart a characteristic colour to the flame.
- (vi) The compounds of s-block elements are predominently ionic and colourless. However, lithium and beryllium compounds are covalent in nature.
- (vii) They have great affinity for oxygen and nonmetals. The oxides are basic. The hydroxides are strong alkalies.
- (viii) They displace hydrogen from acids and form corresponding salts. "

(ix) With exception of Be and Mg, they decompose water and readily evolve hydrogen.

### (ii) p-Block Elements

In the atoms of these elements, the last electron enters the p-subshell of the outermost shell. In these elements npsubshell is gradually filled up. The valency shell configuration varies from  $ns^2 np^1$  to  $ns^2 np^6$ .

Order of the period	ns <sup>2</sup> np <sup>1</sup> (IIIrd group)	ns <sup>2</sup> np <sup>2</sup> (IVth) group)	ns <sup>2</sup> np <sup>3</sup> (Vth group)	ns <sup>2</sup> np <sup>4</sup> (VIth group)	ns <sup>2</sup> np <sup>5</sup> (VIIth group)	ns <sup>2</sup> np <sup>6</sup> (Zero group)

	Group 13	Group 14			Group 17	Group 18

These elements belong to subgroup A in the extended form of periodic table except zero group in which no subgroup is present.] These elements include some metals, all non-metals and metalloids. s-block and p-block elements are collectively called normal or representative elements (except zero group elements). Each period ends with a member of zero group (18th group), i.e., a noble gas with a closed shell ns<sup>2</sup>np<sup>6</sup> configuration. Prior to noble gas group, there are two chemically important groups of non-metals. These are halogens (group 17) and chalcogens (group 16).

### General Characteristics of p-Block Elements

- (i) *p*-block consists of the elements of six groups, *viz.*, IIIA, IVA, VA, VIA, VIIA and zero group. The number of electrons in the outermost shell varies from 3 to 8, i.e., they have general configuration,  $ns^2np^{1-6}$ . The number of electrons in the penultimate shell is either 2 or 8 or 18.
- (ii) Except F and inert gases, p-block elements show a number of oxidation states from +n to (n-8) where n is the number of electrons present in the outermost shell.

Group IIIA IVA VA VIA VIIA
Oxid. states +3 +4 to -4 +5 to -3 +6 to -2 +7 to -1

[Oxygen is an exception. However, it can show -2, -1,  $-1/2(KO_2)$ ,  $-1/3(KO_3)$  and  $+1/2(O_2PtF_6)$  oxidation states.]

- (iii) The *p*-block elements generally show covalency but higher members can show electrovalency. The highly electronegative elements like halogens, O, S, N, etc., show electrovalency by accepting electrons and forming anions. Some of the elements show coordinate valency also.
- (iv) In the period from left to right, there is regular increase in nonmetallic character. However, nonmetallic character decreases in the groups from top to bottom.
- (v) Ionisation energies increase from left to right in a period while decrease in a group from top to bottom. The members of V group and zero group have exceptionally high values of ionisation energies on account of half filled and fully filled orbitals in the valency shell.
- (vi) In every period, reducing nature decreases from left to right while oxidising nature increases. Reducing nature increases in a group from top to bottom. Halogens are strong oxidising agents.
- (vii) Most of them are highly electronegative. The electronegativity increases in a period from left to right and decreases in a group from top to bottom.
  - (viii) Most of them form acidic oxides.
- (ix) No member of *p*-block series or the salts imparts a characteristic colour to the flame.
- (x) Chemical properties change from group to group. It is difficult to summarise them.
- (xi) A number of elements of *p*-block series show the phenomenon of allotropy. Carbon, silicon, phosphorus, sulphur, boron, germanium, tin, arsenic, etc., show this property.
- (xii) Catenation property is shown by many elements of *p*-block series such as carbon, silicon, germanium, nitrogen, oxygen, sulphur, etc.

### **■ (iii)** d-Block Elements (Transition Elements)

The d-block elements are also called **transition metals**. In these elements, the last electron enters (n-1)d-subshell (d-orbitals of the penultimate orbit), i.e., (n-1) d-subshell is gradually filled up. The configuration varies from  $(n-1)d^1$   $ns^2$  to  $(n-1)d^{10}$   $ns^2$ . At certain places, the configurations are different than expected. The general configuration of these elements can be represented as  $(n-1)d^{1-10}$   $ns^0$  or 1 or 2. The elements of IIIB, IVB, VB, VIB, VIIB, VIII, IB and IIB belong to this block. These elements are also called **transition elements** as their properties are intermediate between s- and p-block elements. Transition elements must have incomplete penultimate d-subshell, either in the neutral atom or in any one of its stable oxidation states. All the transition elements are metals. These elements are classified into four series, i.e., 3d, 4d, 5d and 6d series corresponding to the filling of orbitals

of 3d, 4d, 5d and 6d subshells of third, fourth, fifth and sixth energy shells, respectively. Each series starts with a member of third group. Every series consists 10 elements each. The end members of 3d, 4d, 5d and 6d series are the members of second group. The expected configurations of these elements are tabulated in Fig. 1.6. The elements marked with asterisk (\*) have different actual configurations.

	3rd group	2nd group
3d series (1st transition series)	Sc (21) [Ar] 3d <sup>1</sup> 4s <sup>2</sup>	to Zn (30) [Ar] $3d^{10}4s^2$
4d series (2nd transition series)	Y (39) [Kr] $4d^15s^2$	to Cd (48) [Kr] 4d <sup>10</sup> 5s <sup>2</sup>
*5d series (3rd transition series)	La (57) [Xe] 5d <sup>1</sup> 6s <sup>2</sup>	to Hg (80) [Xe] $4f^{14}5d^{10}6s^2$
†6d series (4th transi- tion series)	Ac (89) [Rn] $6d^{1}7s^{2}$	to Unb (112) [Rn] 5f <sup>14</sup> 6d <sup>10</sup> 7s <sup>2</sup>

<sup>\*</sup>The elements from Ce (58) to Lu (71) are not included.

#### General Characteristics of d-Block Elements

The general characteristics of *d*-block elements are :

- (i) They are all metals having high melting and boiling points. They are hard in nature and good conductors of heat and electricity. They are malleable, ductile and possess high tensile strength. They have high densities.
- (ii) The ionisation energies of most of *d*-block elements lie in between those of *s* and *p*-block elements. They are less electropositive than *s*-block elements and more electropositive than *p*-block elements. The members of 5*d* series such as Pt, Au, Hg, etc., are inert under ordinary conditions. They are called **noble metals**.
- (iii) *d*-block elements show variable valency. However, members of IIB group (Zn, Cd and Hg) do not show variable valency.
- (iv) Most of the compounds formed by *d*-block elements are coloured in the solid state or in solution.
- (v) Paramagnetism is common in d-block elements. This is due to the presence of unpaired electrons in (n-1)d orbitals.
- (vi) Most of the transition elements and their compounds act as good catalysts.
- (vii) They have high tendency to form complex compounds.
- (viii) They have high tendency to form alloys with other metals.
  - (ix) They form both ionic and covalent compounds.

### (iv) f-Block Elements (Inner-Transition Elements)

In these elements the last electron enters the (n-2)f energy shell [f-orbitals of the (n-2) main shell], i.e., (n-2)f subshell is gradually filled up. The configuration varies

<sup>†</sup>The elements from Th (90) to Lr (103) are not included.

Fig. 1.6 d-block elements

from  $(n-2)f^1$   $(n-1)d^1$   $ns^2$  to  $(n-2)f^{14}$   $(n-1)d^1$   $ns^2$ . At some places the actual configurations are somewhat different than the expected configurations. Thus, the general configuration can be represented as  $(n-2)f^{0-14}$ ,  $(n-1)d^{0,1 \text{ or } 2}$   $ns^2$ . All f-block elements belong to 3rd group. The f-block elements are of two types:

- **(a) 4***f***-series** (Lanthanides): This series has 14 elements from Ce (58) to Lu (71). In these elements 4*f*-energy shell is gradually filled up.
- **(b)** *5f*-series (Actinides): This series also has 14 elements from Th (90) to Lr (103). In these elements *5f*-energy shell is gradually filled up. These elements are also called **inner transition elements**. All the elements are accommodated in 3rd group but separately written in two horizontal rows below periodic table.

4f-	Ce	Pr	Nd	Pm	Sm	Eu	Gd	Tb	Dy	Но	Er	Tm	Yb	Lu

elements	90	91	92	93	94	95	96	97	98	99	100	101	102	103

Note: Lanthanum ( $_{57}$ La) and actinium ( $_{89}$ Ac) are d-block elements. They are very similar in properties with lanthanides and actinides respectively and are usually studied along with them.

#### General Characteristics of f-Block Elements

The characteristics of *f*-block elements are similar to transition metals, *i.e.*, *d*-block elements. The important characteristics are given below:

- (i) All are metals.
- (ii) They show variable valency. +3 is the most important oxidation state. Few elements show +2 and +4 oxidation states.
  - (iii) They are paramagnetic in nature.
  - (iv) They form coloured compounds.
  - (v) They have tendency to form complexes.
- (vi) Chemically lanthanides are very similar. It is difficult to separate them from a mixture by application of a chemical property. The members of the actinide series are also similar in chemical properties.
- (vii) The members of actinide series are radioactive in nature. Elements above atomic number 92 are not found in nature. These are man-made elements. These are called transuranic elements.

# 1.7 EXTENDED OR LONG FORM OF PERIODIC TABLE

In order to remove the defects of Mendeleev's periodic table, a number of tables have been presented for the classification of elements. The best table out of these is the **extended** or **long form** of periodic table which has been shown in Fig. 1.7.

# Periodic Table of the Elements (Long Form)

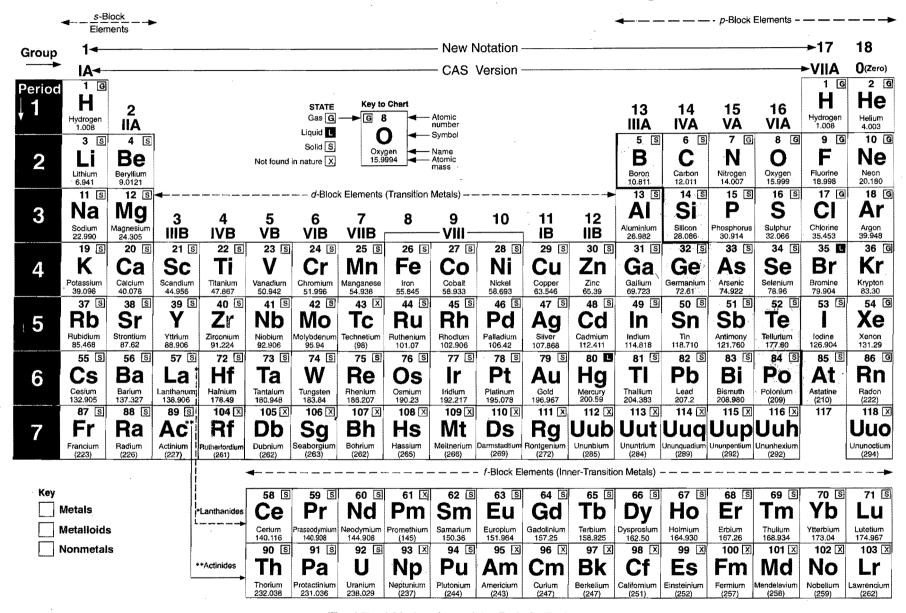

Fig. 1.7 A Modern form of the Periodic Table

the text (1) The new IUPAC format numbers the group from 1 to 18. The previous IUPAC numbering system and the system used by Chemical Abstracts Service (CAS) are also shown. For radioactive elements that do not occur in nature, the mass number of the most stable isotope is given in brackets with the longest half-life.

<sup>(2)</sup> The symbols for elements 104-111 used in this table are those proposed by the American Chemical Society and 112-118 proposed by IUPAC.

<sup>(3)</sup> There is no general agreement on the metalloids. Almost every list includes Si, Ge, As, Sb and Te but some also include B, At and Po in the list.

The credit for this table cannot be given to any single person but it incorporates the modifications suggested by many scientists, especially Rang, Werner, Bohr, Bury, etc. The table is most widely used these days and is also referred to as Bohr's table, since it follows the Bohr scheme of the arrangement of elements into four types based on electronic configuration of the elements. This table is just a graphical representation of the aufbau principle.

# ■ Structural Features of the Long Form of the Periodic Table

Like Mendeleev's periodic table, the long form of the periodic table consists of horizontal rows called **periods** and vertical columns called **groups**. These are described below:

#### **PERIODS:**

Periods are numbered as 1, 2, 3, 4, 5, 6, and 7 from top to bottom. The period number corresponds to the value of n, i.e., principal quantum number for the outermost or valence shell of the atoms of the elements belonging to that period. Number of elements in each period is twice of the atomic orbitals available in the energy level that are being filled.

**1st Period :** In the first period, the first main energy shell (K shell *i.e.*, n = 1) is filled. As it has only one orbital which can accommodate only two electrons, *i.e.*, only two elements are present. The first period consists of hydrogen (1s<sup>1</sup>) and helium (1s<sup>2</sup>).

**2nd Period**: In the second period, the second energy shell (*L*-shell *i.e.*, n=2) is completed. This energy shell has four orbitals, one 2s and three 2p orbitals, which can accommodate eight electrons and therefore, second period has eight elements from Li  $(2s^1)$  to Ne  $(2s^22p^6)$ .

**3rd period :** This period corresponds to the filling of third energy shell, *i.e.*, n = 3. There are nine orbitals, one 3s, three 3p and five 3d-orbitals in this shell. However, on the basis of aufbau principle, the 3d orbitals are higher in energy than 4s orbital. Thus, 3d orbitals are filled after filling of 4s orbital. Hence, only four orbitals, one 3s and three 3p orbitals are filled in this period. Consequently, this period, contains 8 elements from Na  $(3s^1)$  to Ar  $(3s^23p^6)$ .

**4th period:** The fourth period corresponds to the filling of fourth energy shell, *i.e.*, n = 4. Out of 4s, 4p, 4d and

4f-orbitals, the energies of 4d and 4f orbitals are higher than 5s orbital. Thus, 4s and 4p-orbitals are filled. However in between 4s and 4p-orbitals, five 3d-orbitals are also filled as their energies lie in between those orbitals. Hence, nine orbitals, one 4s, five 3d and three 4p-orbitals are filled. The fourth period contains 18 elements from potassium  $(4s^1)$  to krypton  $(3d^{10}4s^24p^6)$ . This period, therefore, includes first d-block series from scandium  $(Z=21, 3d^14s^2)$  to Zinc  $(Z=30, 3d^{10}4s^2)$ . Two s-block elements, ten d-block elements and six p-block elements are present.

**5th period**: Like fourth period, it also accommodates 18 elements as nine orbitals, one 5s, five 4d and three 5p orbitals are filled. It includes elements from rubidium  $(5s^1)$  to xenon  $(4d^{10}5s^25p^6)$ . This period, therefore, contains second d-block series from yttrium  $(Z=39, 4d^{10}5s^2)$  to cadmium  $(Z=48, 4d^{10}5s^2)$ . Two s-block, ten d-block and six p-block elements are present in this period.

**6th period**: The 6s, 4f, 5d and 6p-orbitals (i.e., sixteen orbitals) are filled accommodating 32 elements from caesium  $(6s^1)$  to radon  $(4f^{14}5d^{10}6s^26p^6)$ . This period includes third d-block series from lanthanum  $(Z=57,5d^16s^2$ —Here aufbau principle is violated) to mercury  $(4f^{14}5d^{10}6s^2)$ . The filling of 4f-orbitals begins from cerium  $(Z=58,4f^15d^16s^2)$  and ends up at lutetium  $(Z=71,4f^{14}5d^16s^2)$ . These fourteen elements constitute 4f-series (Lanthanides). As the period can accommodate to the maximum of 18 elements, these 14 elements of 4f-series are separately placed in a horizontal row below the periodic table.

**7th period :** Like sixth period, seventh period is also expected to accommodate 32 elements corresponding to filling of sixteen orbitals, *i.e.*, one 7s, seven 5f, five 6d and three 7p orbitals. However, at present this period is incomplete consisting 31 elements. One element of p-block bearing atomic numbers 117 is to be discovered to complete this period. The period includes two s-block elements, 10d-block elements, 14f-block elements and five p-block elements at present. 14 members of 5f-series (actinides) are also separately accommodated in a horizontal row below the periodic table like 4f-series.

The number of elements and the corresponding orbitals being filled are given in the following table:

Period	Energy level being filled	Orbitals being filled	First member	Last member		Total number of electrons or elements in the period		
1	n = 1	1 <i>s</i>	H(Z=1)	He $(Z=2)$	2	= 2		
2	n = 2	2s 2p	Li $(Z = 3)$	Ne $(Z = 10)$	2 + 6	= 8		
3	n = 3	3s 3p	Na $(Z = 11)$	Ar  (Z = 18)	2 + 6	= 8		
4	n=4	<b>4</b> s 3d <b>4</b> p	K (Z = 19)	Kr (Z = 36)	2 + 10 + 6	= 18		
5	n = 5	5s <b>4</b> d 5p	Rb $(Z = 37)$	Xe   (Z = 54)	2 + 10 + 6	= 18		
6	n = 6	6s 4f 5d 6p	Cs (Z = 55)	Rn $(Z = 86)$	2 + 14 + 10 + 6	= 32		
7	n = 7	7s 5f 6d 7p	Fr (Z = 87)	Uuo $(Z = 118)^*$	2 + 14 + 10 + 6	= 32*		

They are *p*-block elements and their number is quite low. Six of the nonmetals carbon, boron, phosphorus, sulphur, selenium and iodine are solids. Bromine is the only liquid nonmetal at room temperature. The remaining nonmetals—nitrogen, oxygen, fluorine, chlorine, hydrogen and noble gases are gases. Nonmetals are generally (i) brittle (ii) nonlustrous (iii) have low melting and boiling points (carbon and boron are exceptions) (iv) nonconductors of heat (v) capable of forming acidic oxides (vi) do not evolve hydrogen from acids.

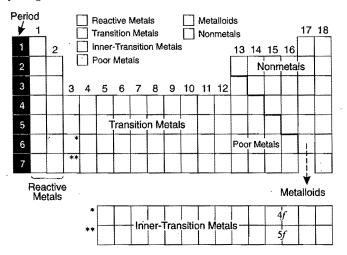

Fig. 1.10 Blocks of elements representing similar properties in the periodic table

#### Metalloids:

There are some elements which do not fit completely into either metal or nonmetal class. Elements which have mixed properties of metals and nonmetals both are called semimetals or metalloids. Silicon, germanium, arsenic, antimony and tellurium are metalloids. But some scientists include boron, polonium and astatine also in the list of metalloids.

In most respects, metalloids behave as non-metals, both chemically and physically. However, in their most important physical property, the electrical conductivity, they somewhat resemble metals. Metalloids tend to be **semiconductors**; they conduct electricity, but not nearly so well as metals. This property, particularly found in silicon and germanium, is responsible for the remarkable progress made during the last fifty years in the field of solid-state electronics. The operations of every computer, audio system, TV receiver, DVD or CD player relies on transistors made from semiconductors.

In periodic table, the metallic character increases from top to bottom in a group while metallic character decreases from left to right along a period.

### Superiority of the Long Form of the Table over Mendeleev's Periodic Table

- (i) This table is based on a more fundamental property, *i.e.*, atomic number.
- (ii) It correlates the position of the element with its electronic configuration more clearly.

- (iii) The completion of each period is more logical. In a period as the atomic number increases, the energy shells are gradually filled up until an inert gas configuration is reached. It eliminates the even and odd series of IV, V and VI periods of Mendeleev's periodic table.
- (iv) The position of VIII group is appropriate in this table. All the transition elements have been brought in the middle as the properties of transition elements are intermediate between *s* and *p*-block elements.
- **(v)** Due to separation of two subgroups, dissimilar elements do not fall together. One vertical column accommodates elements with same electronic configuration thereby showing same properties.
- (vi) In this table a complete separation between metals and nonmetals has been achieved. The nonmetals are present in upper right corner of the periodic table.
- (vii) There is a gradual change in properties of the elements with increase in their atomic numbers, *i.e.*, periodicity of properties can be easily visualised. The same properties of recurrence in properties occur after the intervals of 2, 8, 8, 18, 18 and 32 elements which indicates the capacity of various periods of the table.
- (viii) This arrangement of elements is easy to remember and reproduce.

### Defects of Long Form of Periodic Table

The long form of periodic table has following defects:

- **(i) Position of hydrogen:** The position of hydrogen is not fixed in this table also. It is placed either in IA or in VIIA group.
- (ii) Position of lanthanides and actinides: No individual places have been assigned to these 28 elements in the periodic table.
- (iii) This table does not reflect the exact distribution of electrons among all the orbitals of the atoms of all the elements.

# 1.8 POSITION OF AN ELEMENT ON THE BASIS OF ELECTRONIC CONFIGURATION

The block, period and group of an element can be easily decided from its electronic configuration of the element (Fig. 1.4).

- (i) The block of the element is decided on the basis of the type of the orbital on which the last electron is accommodated. If the last electron enters into s-subshell or *p*-subshell or *d*-subshell or *f*-subshell, then the element belongs to s-block or *p*-block or *d*-block or *f*-block respectively.
- (ii) The period to which an element belongs depends on the total number of orbits (shells) on which electrons are present.

or

The serial number of the period corresponds to the principal quantum number (p.q.no.) of the outermost shell on which the electrons are present.

C1	17	2, 8, 7	[Ne] $3s^23p^5$	belongs to
		Three orbits	p.q.no. 3	3rd period
Pb	82	2, 8, 18, 32, 18, 4,	[Xe] $4f^{14}5d^{10}6s^26p^2$	belongs to
		Six orbits	p.q.no. 6	6th period

- (iii) To decide about the group number (IUPAC), the number of electrons present on the outermost shell or / and penultimate shell [next to the outermost, *i.e.*, (n-1) shell] are counted.
- (a) If the last orbit contains 1 or 2 electrons, the group number is 1 or 2 respectively (Helium is an exception which belongs to group 18). There should not be any d-orbital in the penultimate shell, *i.e.*, in the penultimate shell either 2 electrons  $[(n-1)s^2]$  or 8 electrons  $[(n-1)s^2p^6]$  electrons are present.

ns <sup>1</sup>	→ 1st group	• :	$ns^2 \longrightarrow 2nd grou$	Р
K	19	2, 8, 8, 1	[Ar] 4s <sup>1</sup>	Group 1
Sr	38	2, 8, 18, 8, 2	[Kr] 5s <sup>2</sup>	Group 2
Be	4	2, 2	[He] 2s <sup>2</sup>	Group 2
Li	3	2, 1	[He] 2s <sup>1</sup>	Group 1

(b) If the last orbit has 3 or more electrons, then the group number is the sum of electrons in the last orbit plus 10. Such an element belongs to *p*-block.

s	16	2, 8, 6	[Ne]	$3s^23p^4$	6 + 10 = 16
Ge	32	2, 8, 18, 4	[Ar]	$3d^{10}4s^24p^2$	<i>i.e.</i> , 16th group $4 + 10 = 14$
Xe	54	2, 8, 18, 18, 8	[Kr]	$4d^{10}5s^25p^6$	<i>i.e.</i> , 14th group $10 + 8 = 18$
Αt	85	2, 8, 18, 32, 18, 7	[Xe]	$4f^{14}5d^{10}6s^26p^5$	<i>i.e.</i> , 18th group $10 + 7 = 17$
					i.e., 17th group

(c) If the last orbit contains 1 or 2 electrons and (n-1)d-orbitals where electrons are present, then group number is equal to the sum of electrons in the last orbit and (n-1)d-orbitals. Such an element belongs to d-block.

Cr 24	2, 8, 8 + 5, 1	[Ar] 3d <sup>5</sup>	$4s^1   5+1=6$
Cu 29	2, 8, 8 + 10, 1	[Ar] 3d <sup>1</sup>	i.e., 6th group $10 + 1 = 11$
			i.e., 11th group
Ku 44	2, 8, 18, 8 + 7, 1	[Kr] 4d <sup>7</sup>	7 + 1 = 8 <i>i.e.</i> , 8th group
Hf 72	2, 8, 18, 32, 8 + <b>2</b> , <b>2</b>	[Xe] 4f <sup>14</sup>	
			i.e., 4th group

# 1.9 ATOMIC PROPERTIES OR PERIODIC PROPERTIES OF ELEMENTS

The physical properties of the elements can be divided into two categories :

(i) Properties of individual atoms: Properties such as atomic and ionic radii, ionisation enthalpy, electron gain

enthalpy, valency, screening effect, effective nuclear charge and electronegativity are the properties of individual atoms and directly dependent on their electronic configurations.

(ii) Properties of group of atoms: Properties such as melting point, boiling point, heat of fusion, heat of vaporization, density, atomic volume, etc., are the properties of group of atoms together and are indirectly related to their electronic configurations.

All these properties which are directly or indirectly dependent on the electronic configuration of the elements are called atomic properties.

Since electronic configurations of the elements are periodic function of atomic numbers of the elements, therefore, these atomic properties are also a periodic function of atomic numbers of the elements. On account of this, atomic properties are also called **periodic properties**.

### Periodicity in Properties

The rigid meaning of the word periodic is that a particular property is repeated in a system at regular intervals. The term periodicity in properties in the classification of elements means that same properties of the elements reappear at definite intervals when the elements are arranged in the order of their increasing atomic numbers. In modern periodic table, these intervals are 2, 8, 8, 18, 18 and 32, *i.e.*, similar properties are observed with elements belonging to the same subgroup which have been arranged in subgroups after the difference of either 2 or 8 or 18 or 32 in atomic numbers as similar valency-shell electronic configurations recur after certain regular intervals of atomic number. This is the cause of periodicity in properties.

The real meaning of the word periodic in any classification of elements is that when the elements are arranged in order of their increasing atomic numbers in the same period or a group, there is gradual change (*i.e.*, increase or decrease) in a particular property. In a period, the gradual change is due to the gradual change of electronic configuration from member to member. Some of the properties which depend on electronic configuration of elements such as screening effect, effective atomic number, atomic radii, ionic radii, ionisation potential, electron affinity, electronegativity, etc., follow the general trend of periodicity.

In a group, the chemical properties of the elements remain nearly the same due to same valence shell configuration. There is gradual change in physical properties due to gradual change in the size of atoms due to start of new energy shell.

We shall discuss now the periodicity or periodic trends in some of the properties such as screening effect, effective nuclear charge, atomic and ionic radii, ionisation enthalpy, electron gain enthalpy, electronegativity, etc. We shall restrict our study especially in the case of *s*- and *p*-block (*i.e.*, normal or representative) elements.

# 1.10 THE SCREENING EFFECT OR SHIELDING EFFECT

In a multielectron atom, the electrons of the valency shell (outermost shell) are attracted towards the nucleus and also these electrons are repelled by the electrons present in the inner shells. On account of this, the actual force of attraction between the nucleus and the valency electrons is somewhat decreased by the repulsive forces acting in opposite direction. This decrease in the force of attraction exerted by the nucleus on the valency electrons due to the presence of electrons in the inner shells, is called screening effect or shielding effect. The magnitude of the screening effect depends upon the number of inner electrons, i.e., higher the number of inner electrons, greater shall be the value of screening effect. The screening effect constant is represented by the symbol  $\sigma$ . The magnitude of ' $\sigma$ ' is determined by the Slater's rules. The contribution of inner electrons to the magnitude of  $'\sigma'$  is calculated in the following ways:

### For *ns* or *np* Orbital Electrons

- (i) Write the electronic configuration of the element in the following order and group them as,
- (1s), (2s 2p), (3s 3p), (3d), (4s 4p), (4d 4f), (5s 5p), (5d 5f), (6s 6p), etc.
- (ii) Electrons to the right of the (ns, np) group are not effective in shielding the ns or np electrons and contribute nothing to  $\sigma$ .
- (iii) All other electrons in the (*ns*, *np*) group contribute to the extent of 0.35 each to the screening constant (except for 1s for which the value is 0.30).
- (iv) All the electrons in the (n-1)th shell contribute 0.85 each to the screening constant.
- (v) All the electrons in the (n-2)th shell or lower contribute 1.0 each to the screening constant.

#### For d- or f-electrons

Rules (i) to (iii) remain the same but rules (iv) and (v) get replaced by the rule (vi).

(vi) All the electrons in the groups lying left to (nd, nf) group contribute 1.0 each to the screening effect.

**Example 1.** Calculation of screening constants of alkali metals for valency electrons.

Li 2, 
$$1 = 2 \times 0.85$$
 = 1.7  
Na 2,  $8$ ,  $1 = 8 \times 0.85 + 2 \times 1$  = 8.8  
K 2,  $8$ ,  $8$ ,  $1 = 8 \times 0.85 + 10 \times 1$  = 16.8  
Rb 2,  $8$ ,  $18$ ,  $8$ ,  $1 = 8 \times 0.85 + 28 \times 1$  = 34.8  
Cs 2,  $8$ ,  $18$ 

**Example 2.** Calculation of screening constants of members of second period for valency electrons.

Li 
$$2, 1 = 2 \times 0.85 = 1.7$$
  
Be  $2, 2 = 0.35 + 2 \times 0.85 = 2.05$ 

B 2, 
$$3 = 2 \times 0.35 + 2 \times 0.85 = 2.40$$
  
C 2,  $4 = 3 \times 0.35 + 2 \times 0.85 = 2.75$   
N 2,  $5 = 4 \times 0.35 + 2 \times 0.85 = 3.10$   
O 2,  $6 = 5 \times 0.35 + 2 \times 0.85 = 3.45$   
F 2,  $7 = 6 \times 0.35 + 2 \times 0.85 = 3.80$   
Ne 2,  $8 = 7 \times 0.35 + 2 \times 0.85 = 4.15$ 

**Example 3.** Calculation of screening constants in zinc (a) for a 4s-electron (b) for a 3d-electron.

- (a) The electronic configuration of zinc (30) is,  $(1s)^2 (2s 2p)^8 (3s 3p)^8 (3d)^{10} (4s)^2$  $\sigma = 10 \times 1.0 + 18 \times 0.85 + 1 \times 0.35 = 25.65$
- (b) For 3*d*-electron,

$$\sigma = 18 \times 1.0 + 9 \times 0.35 = 21.15$$

It is clear from the examples (1) and (2) that the magnitude of screening constant in the case of s- and p-block elements increases in a period as well as in a group as the atomic number increases.

From the example (3), it is evident that the electrons in different orbitals are differently affected by the same nuclear charge depending upon their proximity to the nucleus.

### 1.11 EFFECTIVE NUCLEAR CHARGE

Due to screening effect the valency electron experiences less attraction towards nucleus. This brings decrease in the nuclear charge (Z) actually present on the nucleus. The reduced nuclear charge is termed **effective nuclear charge** and is represented by  $Z^*$ . It is related to actual nuclear charge (Z) by the following formula:

$$Z^* = (Z - \sigma)$$
, where  $\sigma$  is screening constant.

It is observed that magnitude of effective nuclear charge increases in a period when we move from left to right.

II period	Li	Be	В	C	N	О	F	Ne
Z	3	4	. 5	6	7	8	9	10
σ								
$Z^* = (Z - \sigma)$	1.3	1.95	2.60	3.25	3.90	4.55	5.20	5.85

In a subgroup of normal elements the magnitude of effective nuclear charge remains almost the same.

Alkali group	Li	Na	K	Rb	Cs
$Z^{\tau}$	3	11	19	37	55
σ	1.7	8.8	16.8	34.8	52.8
$Z^* = (Z - \sigma)$	1.3	2.2	2.2	2.2	2.2
IIA group	Be	Mg	Ca	Sr	Ba
Z	4	- 12	20	38	- 56
σ	2.05	9.15	17.15	35.15	53.15
$Z^* = (Z - \sigma)$	1.95	2.85	2.85	2.85	2.85

### 1.12 ATOMIC RADIUS

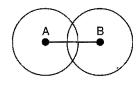

An atom is assumed to be spherical in shape and, thus, the size of atom is generally given in terms of radius of the sphere and is called atomic radius. It is usually defined as the distance between the centre of the nucleus and outermost shell where electron or electrons are present. The exact measure of atomic radius is not easy due to following reasons:

- (i) The atom does not have well defined boundary. The probability of finding the electron is never zero even at large distances from the nucleus.
- (ii) It is not possible to get an isolated atom. The electron density around an atom is affected by the presence of neighbouring atoms, *i.e.*, the size of the atom changes in going from one set of environment to another.
- (iii) The size of an atom is very small, of the order of about  $1.2\text{\AA}$ , i.e.,  $1.2 \times 10^{-10}$  m.

An estimate of the size of the atom can, however, be made by knowing the distance between the atoms in the combined state. The distance between the atoms, *i.e.*, bond lengths are generally measured by the application of techniques such as X-ray diffraction, electron diffraction, infrared spectroscopy, nuclear magnetic resonance spectroscopy, etc. However, bond lengths change with different type of bonding. Three types of radius are commonly used, *i.e.*, (a) covalent radius (b) crystal radius (c) van der Waals' radius.

(a) Covalent radius: Covalent radius is defined as half of the distance between two nuclei of two like atoms

bonded together by a single covalent bond. Consider a homonuclear diatomic molecule  $A_2$ , bonded together by single covalent bond. It is assumed that electron clouds of each atom touch each other. Let the bond length be  $d_{A-A}$ . Then  $d_{A-A} = r_A + r_A = 2r_A$ .

So 
$$r_A = \frac{d_{A-A}}{2}$$

In a hetero-nuclear diatomic AB molecule if both atoms are linked by a single covalent bond and have nearly same electronegativity, the bond length  $d_{A-B}$  is equal to sum of covalent radius of the two atoms.

$$d_{A - B} = r_A + r_B$$

Knowing the bond length and covalent radius of one of the atoms, the radius of the other atom can be determined. Covalent radius is used for non-metals.

[When there is large difference in the electronegativity of two elements A and B, the bond between A and B will have somewhat ionic character and the bond length  $d_{A op B}$  will be shorter than expected. In such cases, the following relationship should be used :

$$d_{A-B} = r_A + r_B - 0.09(X_A - X_B)$$

 $X_A$  and  $X_B$  are the electronegativities of elements A and B.

For example,

- (a) Bond length ( $d_{H-H}$ ) in hydrogen molecule is 0.74Å.
- ∴ Covalent radius of hydrogen =  $\frac{d_{H-H}}{2} = \frac{0.74}{2} = 0.37 \text{ Å}$
- (b) Bond length ( $d_{Cl-Cl}$ ) in chlorine molecule is 1.98Å.

∴ Covalent radius of chlorine = 
$$\frac{d_{\text{Cl--Cl}}}{2} = \frac{1.98}{2} = 0.99 \text{ Å}$$

(c) Bond length  $(d_{C-C})$  in diamond is 1.54Å.

$$\therefore$$
 Covalent radius of carbon =  $\frac{d_{C-C}}{2} = \frac{1.54}{2} = 0.77 \text{ Å}$ 

(d) Bond length ( $d_{Si-C}$ ) in carborundum is 1.93Å.

$$d_{\text{Si}-C} = r_{\text{Si}} + r_{\text{C}}$$
  
or  $1.93 = r_{\text{Si}} + 0.77$  (:  $r_{\text{C}} = 0.77\text{Å}$ )  
or  $r_{\text{Si}} = 1.93 - 0.77 = 1.16\text{Å}$ 

(e) Bond length  $(d_{C-C_1})$  in CCl<sub>4</sub> is 1.76Å.

.. 
$$d_{C-Cl} = r_C + r_{Cl}$$
  
or  $1.76 = r_C + 0.99$  (·  $r_{Cl} = 0.99\text{Å}$ )  
or  $r_C = 1.76 - 0.99 = 0.77\text{Å}$ 

**Note:** Elements may have multiple bonds in compounds which are always shorter than single bonds.

$$C \longrightarrow C$$
,  $C \Longrightarrow C$   
1.54Å 1.33Å 1.20Å

The double and triple bond radii are calculated in the similar fashion as single covalent radius.

Double bond radius of carbon = 1.33/2 = 0.665Å

Triple bond radius of carbon = 1.20/2 = 0.60Å

The double and triple bond radii of an atom are approximately 0.87 and 0.78 times the single bond radius respectively.

(b) Crystal Radius: It is used for metal atoms which are assumed to be closely packed spheres in the metallic crystal, i.e., atoms are supposed to touch one another: It is defined as one half the distance between the nuclei of two adjacent metal atoms in the metallic closed packed crystal lattice in which the metal exhibits a coordination number of 12. It is also called metallic radius.

For example, the distance between the two adjacent potassium atoms in solid potassium is 4.62Å. Therefore, the metallic radius of potassium is 4.62/2 = 2.31 Å.

A metallic radius is always longer than covalent radius.

Metal	Covalent radius (Å)	Crystal radius (Å		
Sodium	1.54	1.86		
Potassium	2.03	2.31		
Copper	1.17	1.28		
Barium	1.98	2.22		
Aluminium	1.20	1.43		

Atomic radius is expressed either in nanometre (1 nm =  $10^{-9}$  m) or in angstrom (1 Å =  $10^{-10}$  m) or in picometre (1 pm =  $10^{-12}$  m).

(c) van der Waals' radius: It is half of the distance between the nuclei of two non-bonded neighbouring atoms of two adjacent molecules in solid state.

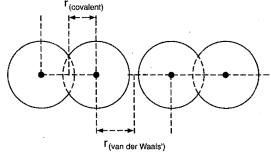

Fig. 1.12 Comparison of covalent and van der Waals' radius

The magnitude of the van der Waals' radius depends upon the packing of molecules of the element in solid state. For example, the distance between adjacent chlorine atoms of the two neighbouring molecules in solid state is 3.6Å. Therefore, the van der Waals' radius of chlorine is 3.6/2 = 1.8 Å.

van der Waals' radius of an element is always larger than its covalent radius.

A comparison of three types of radius shows that covalent radius of an atom is shortest while van der Waals' radius is the longest.

van der Waals' radius > Crystal radius > Covalent radius van der Waals' forces are weak, thus the distances between the atoms held by these forces are much larger than held by covalent bonding. A covalent bond is formed by overlap of two half filled atomic orbitals, thus a part of the electron cloud becomes common between two atoms. Due to these reasons van der Waals' radius is always higher than covalent radius. In case of a crystal, the valence electrons of the atoms are mobile, therefore, they are only weakly attracted. The metallic forces are thus weaker than covalent forces. On account of this, crystal (metallic) radius is larger than covalent radius.

[van der Waals' forces < Metallic forces < Covalent forces]

Note: For simplicity, we may use the term atomic radius for both covalent or crystal (metallic) radius depending on whether the element is a non-metal or a metal. However, the atomic radii of inert gases are usually expressed in terms of van der Waals' radii as they do not form chemical compounds.

#### Variation of Atomic Radii

(a) Variation in a Period: As we move from left to right across a period, there is regular decrease in atomic radii of the representative elements. This is due to the fact that number of energy shells remain the same in a period but nuclear charge increases gradually as the atomic number increases. This increases the force of attraction towards nucleus which brings contraction in size. This can also be explained on the basis of effective nuclear charge which increases gradually in a period, *i.e.*, electron cloud is attracted more strongly towards nucleus as the effective nuclear charge becomes more and more as we move in a period. The increased force of attraction brings contraction in size.

Atomic radius 
$$\propto \frac{1}{Z_{\text{eff.}}}$$
  $(Z_{\text{eff.}} = Z - \sigma)$ 

 $Z_{eff.}$  = Effective nuclear charge; Z = Atomic number;  $\sigma$  = Shielding effect

2nd period Li Be B C N O F 
$$Z_{\rm eff.}=(Z-\sigma)$$
 (3-1.7) (4-2.05) (5-2.40) (6-2.75) (7-3.10) (8-3.45) (9-3.80) = 1.3 = 1.95 = 2.60 = 3.25 = 3.90 4.55 = 5.20 Atomic 1.23 0.89 0.80 0.77 0.75 0.73 0.72 radius (Å)

**(b)** Variation in a Group: Atomic radii in a group increase as the atomic number increases. The increase in size is due to extra energy shells which outweigh the effect of increased nuclear charge. The following table illustrates

the periodicity in atomic radii (covalent radii) of representative elements. The radii are in angstroms.

Period/Group→	I	. II	III	IV	V	VI	VII	
↓ 1	H 0.37							
2	Li	Be	В	С	N	О	F	
•	1.23	0.89	0.80	0.77	0.75	0.73	0.72

	2.35	1.98	1.48	1.47	1.46	1.46		
<del>3112</del>			Decrea	ses		,	•	•

The atoms of zero group elements do not form chemical bonds. Hence, their van der Waals' radii are considered which are always larger than covalent radii of halogens.

The decrease in the size of transition elements is small since the differentiating electrons enter into inner 'd' levels. The additional electrons into (n-1)d levels effectively screen much of increased nuclear charge on the outer ns electrons and therefore, size remains almost constant.

However, in vertical columns of transition elements, there is an increase in size from first member to second member as expected but from second member to third member, there is

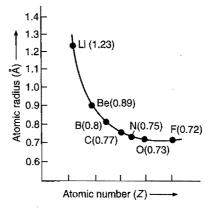

Fig. 1.13 Variation of atomic radii (covalent) in a period

very small change in size and sometimes sizes are same. This is due to **Lanthanide contraction** (in the lanthanide elements

differentiating electrons enter into 4*f* levels. Since these electrons do not effectively screen the valency electrons from the increased nuclear charge, the size gradually decreases. This decrease is termed lanthanide contraction).

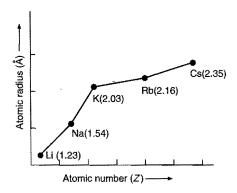

Fig. 1.14 Variation of atomic radius (covalent) down a group

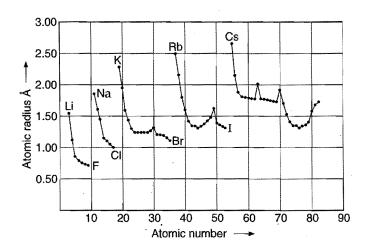

Fig. 1.15 Variation in atomic radii in periods (Metallic radii for metals and covalent radii for non-metals)

Element	Ce	Pr	Nd	Pm	Sm		Tb	 Lu
Atomic radius Å	1.65	1.65	1.64	1.63	1.62	•	1.59	1.56
(Covalent)								

The increase in size that arises due to period change in second and third transition series is almost compensated by the lanthanide contraction.

1st Tr. series	Sc	Ti	V	Cr .	 Cu
At. radius Å (Covalent)	1.44	1.32	1.22	1.17	1.17
2nd Tr. series	Y	Zr	Nb	Mo	 Ag
At. radius Å (Covalent)	1.62	1.45	1.34	1.29	1.34
3rd Tr. series	La	Hf	Ta	· W	 Au
At. radius Å (Covalent)	1.69	1.45	1.34	1.30	1.34

The following table illustrates the metallic radii (Crystal radii) in angstroms:

L1	Вe														
1.52	1.12

2.65	2.22	1.87	1.59	1.47	1.41	1.37	1.35	1.36	1.39	1.44	1.57	1.70	1.75	1.70	

### **Conclusions**

- (i) The alkali metals which are present at the extreme left of the periodic table have the largest size in a period.
- (ii) The halogens which are present at the extreme right of the periodic table have the smallest size.
- (iii) The sizes of the atoms of inert gases are, however, larger than those of preceding halogens because in inert gases van der Waals' radii are taken into consideration.
- (iv) In transition series, the decrease in size is small as the additional electrons in (n-1)d levels effectively screen much of the nuclear charge on the ns electrons.
- (v) In 4f-series, there is continuous decrease in size with increase in atomic number. This decrease is termed Lanthanide contraction.
- (vi) In a group of normal elements, there is continuous increase in size with increase in atomic number.
- (vii) In a group of transition elements, there is an increase in size from first member to second member as expected but from second member to third member, there is very small change in size and sometimes sizes are same. This is due to Lanthanide contraction.

### 1.13 IONIC RADIUS

Ionic radii are related to the ions present in ionic (crystalline) solids. Ions are formed when neutral atoms lose one or more electrons or gain one or more electrons. A positive ion results when a neutral atom loses one or more electrons. A positive ion is called **cation**. A negative ion is formed when a neutral atom gains one or more electrons. The negative ion is termed anion. The effective size of these ions is termed ionic radius. It is defined as the distance between the nucleus and outermost shell of an ion or it is the distance between the nucleus and the point where the nucleus exerts its influence on the electron cloud.

Like atomic radii, the accurate measurement of ionic radii is also not easy. However, the internuclear distance between two oppositely charged ions in a crystal can be taken as the sum of the radius of cation and radius of the anion by assuming spherical shapes of the ions and both are touching each other. X-ray technique is used to measure the internuclear distances. Knowing the radius of one ion, the radius of the other ion can be calculated.

For example, in NaCl crystal, the internuclear distance of two ions is 2.76Å. The radius of Na $^+$  ion is 0.95Å (Pauling theoretical method). Therefore, the radius of Cl $^-$  ion is 2.76 – 0.95 = 1.81Å.

### Comparison of the Ionic Radii with Corresponding Atomic Radii

- (a) The radius of the cation is always smaller than the atomic radius of its parent atom. This is due to the fact that nuclear charge in the case of a cation is acting on a lesser number of electrons and pulls them closer, *i.e.*, effective nuclear charge of a cation is always greater than the neutral atom and thus, electron cloud contracts.
- **(b)** The radius of the anion is always larger than the atomic radius of its parent atom. In an anion as electron or electrons are added to the neutral atom, the nuclear charge acts on more electrons so that each electron is held less tightly and thereby the electron cloud expands, *i.e.*, effective nuclear charge of an anion is always smaller than the neutral atom and thus, electron cloud expands.

**Comparative Sizes of Atoms and their Cations** 

Atom	Atomic radii (crystal, Å)	Corresponding cations	Ionic radii (Å)
Li	1.52	Li <sup>+</sup>	0.59
Na	1.86	Na <sup>+</sup>	0.99
K	2.31	K <sup>+</sup>	1.33
Mg	1.60	Mg <sup>2+</sup> Ba <sup>2+</sup>	0.65
Ва	2.22		1.35
Al	1.43	Al <sup>3+</sup>	0.50
Pb	1.75	Pb <sup>2+</sup>	1.32

#### **Comparative Sizes of Atoms and their Anions**

Atom	Atomic radii (covalent, Å)	Corresponding anions	Ionic radii (Å)
F	0.72	F	1.36
Cl	0.99	Cl <sup></sup>	. 1.81
Br	1.14	Br <sup></sup>	1.96
О	0.73	$O^{2-}$	1.40
S	1.04	S <sup>2-</sup>	1.84
N	0.75	N <sup>3</sup>	1.71
P	1.10	P <sup>3-</sup>	2.12

In any particular group, the ions (cations or anions) increase in size on moving from top to bottom. This is due to an increase in the number of shells. For example,

The size of the cations of the same element decreases with the increase of positive charge. For example,  $Pb^{4+}$  is smaller in size than  $Pb^{2+}$ ;  $Sn^{4+}$  is smaller in size than  $Sn^{2+}$ ;  $Fe^{3+}$  is smaller in size than  $Fe^{2+}$ .

$$Fe^{3+}$$
 0.67 Å  $Cu^{2+}$  0.72  $Co^{3+}$  0.64  $Fe^{2+}$  0.82 Å  $Cu^{+}$  0.96  $Co^{2+}$  0.82

This can be explained on the basis of Z/e ratio  $\left(\frac{\text{Nuclear charge}}{\text{No. of electrons}}\right)$ . Whenever Z/e ratio increases, the size decreases and when Z/e ratio decreases, the size increases.

Na Na\* Cl Cl Fe<sup>2+</sup> Fe<sup>3+</sup> 
$$Z/e$$
  $\frac{11}{11} = 1.0$ ;  $\frac{11}{10} = 1.1$ ;  $\frac{17}{17} = 1.0$ ;  $\frac{17}{18} = 0.95$ ;  $\frac{26}{24} = 1.08$ ;  $\frac{26}{23} = 1.13$  So Na\* < Na Cl > Cl Fe<sup>3+</sup> < Fe<sup>2+</sup>

Isoelectronic species (ions or atoms) are those which have same number of electrons. For such species the size decreases with an increase of atomic number. This is illustrated in the following table:

Atom or Ion	Atomic number Z	No. of electrons <i>e</i>	Z/e ratio	Size in Å
C <sup>4-</sup> N <sup>3-</sup>	6	10	0.6	2.60
$N^{3-}$	7	10	0.7	1.71
O <sup>2-</sup>	8	10	0.8	1.40
F-	9	10	0.9	1.36
Ne	10	10	1.0	1.12
Na <sup>+</sup>	11	10	1.1	0.99
Mg <sup>2+</sup> Al <sup>3+</sup>	12	10	1.2	0.65
Al <sup>3+</sup>	13	10	1.3	0.50

H<sup>+</sup> and Cs<sup>+</sup> are the smallest and largest cations respectively.

H and I are the smallest and largest anions respectively.

#### **Conclusions**

- (i) The radius of cation (positive ion) is always smaller than that of the parent atom.
- (ii) The radius of anion (negative ion) is always larger than that of the parent atom.
- (iii) The ionic radii in a particular group increase in moving from top to bottom.
- (iv) In a set of species having the same number of electrons (isoelectronic), the size decreases as the charge on the nucleus increases.
- (v) The size of the cations of the same element decreases with the increase of positive charge.

# 1.14 IONISATION ENTHALPY OR IONISATION POTENTIAL

The electrons in an atom are attracted by the positive charge present on the nucleus. To remove an electron from an atom, energy has to be supplied to overcome the force of attraction towards nucleus. A quantitative measure of the tendency of an atom of an element to lose electron is given by its ionisation enthalpy. It is defined as the minimum amount of energy required to remove most loosely bound electron from an isolated atom in the gaseous state of an element so as to convert it into gaseous monovalent positive ion. It is also known as first ionisation enthalpy or energy. The process can be represented as:

$$M(g) \xrightarrow{\text{+energy}} M^+(g) + e$$

or 
$$M(g) + IE_1 \text{ or } *\Delta_i H_1 \longrightarrow M^+(g) + e$$

Ionisation enthalpy is also called as ionisation potential as it is the minimum potential difference in a discharge tube required to remove the most loosely bound electron from an isolated gaseous atom to form gaseous cation.

Ionisation enthalpy (or potential) is expressed either in terms of electron volts per atom (eV/atom) or kilocalories per mole (kcal mol<sup>-1</sup>) or kilojoules per mole (kJ mol<sup>-1</sup>).

1 electron volt (eV) per atom

$$= 3.83 \times 10^{-20}$$
 cal per atom  $= 1.602 \times 10^{-19}$  J per atom

$$= 3.83 \times 10^{-20} \times 6.023 \times 10^{23} \text{ cal mol}^{-1}$$

 $= 23.06 \text{ kcal mol}^{-1}$ 

= 
$$1.602 \times 10^{-19} \times 6.023 \times 10^{23} \text{ J mol}^{-1}$$

 $= 96.49 \text{ kJ mol}^{-1}$ 

 $\therefore$  1 eV per atom = 23.06 kcal mol<sup>-1</sup> = 96.49 kJ mol<sup>-1</sup>

Like the removal of first electron from isolated gaseous atom, it is possible to remove second, third and successive electrons from positive ions one after the other. The amounts of energies required are termed second, third, fourth ...... ionisation enthalpies respectively. These processes can be shown as:

$$M^{+}(g) + \Delta_{i}H_{2} \text{ or } IE_{2} = M^{2+}(g) + e$$
  
 $M^{2+}(g) + \Delta_{i}H_{3} \text{ or } IE_{3} = M^{3+}(g) + e$   
 $M^{3+}(g) + \Delta_{i}H_{4} \text{ or } IE_{4} = M^{4+}(g) + e$ 

It is observed that  $\Delta_i H_2(IE_2)$  has higher value than  $\Delta_i H_1(IE_1)$ .  $\Delta_i H_3$  is higher than  $\Delta_i H_2$  and so on, *i.e.*,

$$\Delta_i H_1 < \Delta_i H_2 < \Delta_i H_3 < \Delta_i H_4$$

The successive ionisation enthalpies of first ten elements are given in the following table:

### Successive Ionisation Energies of the First Ten Elements (kJ/mol)\*\*

Element	Electronic configuration	First	Second	Third	Fourth	Fifth	Sixth	Seventh
Н	$1s^1$	1312	,					
He	$1s^2$	2372	5250					
Li	$1s^2$ , $2s^1$	520	7298	11,815		•		
Be	$1s^2$ , $2s^2$	899	1757	14,848	21,006		*	
В	$1s^2$ , $2s^22p^1$	801	2427	3660	25,025	32,826		
C	$1s^2$ , $2s^22p^2$	1086	2353	4620	6222	37,829	47,276	
N	$1s^2$ , $2s^22p^3$	1402	2857	4578	7475	9445	53,265	64,358
O	$1s^2$ , $2s^22p^4$	1314	3388	5300	7469	10,989	13,326	15,160
F	$1s^2$ , $2s^22p^5$	1681	3374	6020	8407	11,022	15,164	17,867
Ne	$1s^2$ , $2s^22p^6$	2081	3952	6122	9370	12,177	15,238	19,998

<sup>\*\*</sup>Ionisation energies to the right of a vertical line correspond to removal of electrons from the core of the atom.

The increase in the values of successive ionisation enthalpies can be explained on the basis that effective nuclear charge increases from M(g) to  $M^{n+}(g)$ , *i.e.*, electrostatic attraction between the nucleus and the remaining electrons in the cation (especially the outermost electron in the cation)

increases. This requires higher energy to remove the electron from the cation in comparison to neutral atom. The energy increases as the charge on the cation increases gradually. Thus, successive ionisation enthalpies have higher values.

<sup>\*</sup>H represents enthalpy and ΔH, change in enthalpy. It is given positive sign if energy is required and negative sign if it is released.

an **endoergic** process and will be given a positive sign. Similarly, higher electron gain enthalpies are positive. For example, when an electron is added to an oxygen atom to form O<sup>-</sup> ion, energy is released. However, when second electron is added to O<sup>-</sup> ion to form O<sup>2-</sup> ion, energy is absorbed.

$$O(g) + e \longrightarrow O^{-}(g)$$
; 1st  $\Delta H_{eg} = -141 \text{ kJ mol}^{-1}$  (Energy released)  
 $O^{-}(g) + e \longrightarrow O^{2-}(g)$ ; 2nd  $\Delta H_{eg} = +780 \text{ kJ mol}^{-1}$  (Energy absorbed)

Similarly for sulphur atom, the second electron gain enthalpy is positive.

$$S(g) + e \longrightarrow S^{-}(g)$$
; 1st  $\Delta H_{eg} = -200 \text{ kJ mol}^{-1}$   
 $S^{-}(g) + e \longrightarrow S^{2-}(g)$ ; 2nd  $\Delta H_{eg} = +590 \text{ kJ mol}^{-1}$ 

The magnitude of electron affinity depends on a number of factors such as:

- **(i) Size of the atom :** Smaller the size of the atom, stronger is the attraction for the added electron towards nucleus. Thus, smaller the size of atom, greater is the electron affinity.
- **(ii) Nuclear charge:** Greater the nuclear charge, stronger is the attraction for the added electron towards nucleus. Thus, electron affinity increases as nuclear charge increases.
- (iii) Electronic configuration: The elements having stable configuration (half filled or fully filled valence subshells) have very little or no tendency to accept additional electron; hence, electron affinities are low or zero in these cases.

### Variation of Electron Gain Enthalpies in Periodic Table

In general, the electron gain enthalpy becomes less negative in going from top to bottom in a group and more negative in going from left to right in a period. However, electron gain enthalpy does not show a regular trend along a period or a group. The electron gain enthalpies of normal elements are given in the following table in kJ mol<sup>-1</sup>:

$\begin{array}{c} \text{Period} \ \downarrow \\ \text{Group} \rightarrow \end{array}$	1	2	13	14	15	16	17	18
1	H -73				,			He +48
2	Li	Be	B	C	N	O	F	Ne
	-60	+66	-83	-122	+31	-141	-328	+116
3	Na	Mg	Al	Si	P	S	Cl	Ar
	-53	+67	-50	-119	-74	-200	-349	+96
4	K	Ca	Ga	Ge	<b>A</b> s	Se	Br	<b>Kr</b>
	-48	-	-36	-116	-77	-195	-325	+96
5	Rb	Sr	In	Sn	Sb	Te	I	Xe
	-47	-	29	-120	-101	-1 <b>9</b> 0	-295	+77
6	Cs	Ва	T1	Pb	Bi	Po	At	Rn
	-46		-30	-101	-1 <b>1</b> 0	-174	-270	+68

From the table, the following trends are observed:

(i) The electron gain enthalpies, in general, become less negative in going down from top to bottom in a group. This is due to increase in size on moving down a group. This factor is predominant in comparison to other factor, *i.e.*, increase in nuclear charge.

(ii) The electron gain enthalpies of oxygen and fluorine, the members of the second period, have less negative values than the elements sulphur and chlorine of the third period.

This is due to small size of the atoms of oxygen and fluorine. As a result, there is a strong inter-electronic repulsion when extra electron is added to these atoms, *i.e.*, electron density is high and the addition of electron is not easy. Thus, the electron gain enthalpies of third period elements, sulphur and chlorine, have more negative values than corresponding elements oxygen and fluorine.

O 
$$-141 \text{ kJ mol}^{-1}$$
 F  $-328 \text{ kJ mol}^{-1}$   
S  $-200 \text{ kJ mol}^{-1}$  Cl  $-349 \text{ kJ mol}^{-1}$ 

Similar trend is observed in nitrogen and phosphorus.

- (iii) In general, electron gain enthalpy becomes more and more negative from left to right in a period. This is due to decrease in size and increase in nuclear charge as the atomic number increases in a period. Both these factors favour the addition of an extra electron due to higher force of attraction by the nucleus for the incoming electron.
- (iv) Electron gain enthalpies of some of the members of alkaline earth metals, noble gases and nitrogen are positive.

This is because they have stable configurations. Alkaline earth metals have stable configurations due to completely filled ns orbital while nitrogen has extra stability due to half filled p-orbitals  $(1s^2, 2s^2 2p_x^1 2p_y^1 2p_z^1)$ , i.e., symmetrical configuration. These atoms resist the addition of extra electron as they do not want to disturb their stability.

Noble gases have  $ns^2np^6$  configuration, *i.e.*, no place for incoming electron. In case the extra electron is to be accommodated, it will occupy its position on a new principal shell, *i.e.*, it will be weakly attracted towards nucleus. Such anion will be extremely unstable. Helium has also a stable  $1s^2$  configuration and cannot accommodate the incoming electron.

- (v) Halogens have highest negative electron gain enthalpies. Following two factors are responsible for this:
- (a) Small atomic size and high nuclear charge of halogens in a period.

(b) Halogens have the general electronic configuration of  $ns^2np^5$ , i.e., one electron less than stable noble gas  $(ns^2np^6)$  configuration.

Thus, halogens have a very strong tendency to accept an additional electron and their electron gain enthalpies are, therefore, high.

### Importance of Electron Gain Enthalpy

Certain properties of the elements can be predicted on the basis of values of electron gain enthalpies.

- (i) The elements having high negative values of electron gain enthalpy are capable of accepting electron easily. They form anions and thus form ionic (electrovalent) compounds. These elements are **electronegative** in nature.
- (ii) The elements having high negative electron gain enthalpies act as strong oxidising agents, for example, F, Cl, Br, O, S, etc.

On the basis of the general trend of ionisation enthalpy and electron gain enthalpy, the following properties can be predicted:

(i) Metallic nature decreases in a period while non-metallic nature increases. Metallic nature increases in a group while non-metallic nature decreases. The arrow  $(\downarrow)$  represents a group and  $(\rightarrow)$  represents a period.

$$\begin{array}{c|c} & Metallic & Non-metallic \\ Metallic & \longrightarrow Decreases \\ (Electro +ve) & Decreases \\ & Increases & Decreases \\ \end{array}$$

(ii) Stability of metal increases while activity of the metal decreases in a period and in a group stability decreases while activity increases.

This trend is observed especially in IA, IIA and IIIA elements.

(iii) The basic nature of the oxides decreases in a period while acidic nature increases. In a group, basic nature increases while acidic nature decreases.

### 1.16 ELECTRONEGATIVITY

This is the property of a bonded atom. The relative tendency of an atom to attract the shared electron pair towards itself is called electronegativity. Electron gain enthalpy and electronegativity both measure the power of attracting electrons but electron gain enthalpy is concerned with an isolated gaseous atom while electronegativity is concerned with the atom in combination. Electronegativity concept was introduced by Pauling in 1932. An arbitrary value of 4.0 has been assigned to fluorine (most electronegative element) and the electronegativities of other elements have been calculated against this standard by the application of following formula:

$$X_A - X_B = 0.208[E_{A - B} - \frac{1}{2}(E_{A - A} + E_{B - B})]^{\frac{1}{2}}$$

where  $X_A$  and  $X_B$  are the electronegativities of two atoms A and B and  $E_{A\_B}$ ,  $E_{A\_A}$  and  $E_{B\_B}$  are bond energies of molecules A-B,  $A_2$  and  $B_2$ , respectively in kcal mol<sup>-1</sup> or  $X_A-X_B=0.102$   $[E_{A\_B}-\frac{1}{2}(E_{A\_A}+E_{B\_B})]^{\frac{1}{2}}$ , if the bond energies are taken in kJ mol<sup>-1</sup>.

Mulliken regarded electronegativity as the average value of ionisation potential and electron gain enthalpy of an atom when both are taken in electron volts.

Electronegativity = 
$$\frac{IP + EA}{2}$$

[IP = Ionisation enthalpy; EA = Electron gain enthalpy]

However, it was found that Mulliken values were 2.8 times greater than Pauling values.

Thus, electronegativity in Pauling scale = 
$$\frac{IP + EA}{2 \times 2.8}$$
$$= \frac{IP + EA}{5.6}$$

Electronegativity of an atom on Pauling scale if the values are taken in kcals per mole =  $\frac{IP + EA}{2 \times 2.8 \times 23.06}$ 

Electronegativity of an atom on Mulliken scale if the values of IP and EA are taken in kJ mol<sup>-1</sup> =  $\frac{IP + EA}{2 \times 96.48}$ 

Thus, electronegativity of an atom on Pauling scale

$$=\frac{IP + EA}{2 \times 96.48 \times 2.8} = \frac{IP + EA}{540}$$

On Allred and Rochow scale, the electronegativity is calculated by applying the following formula,

$$X_A = 0.744 + \frac{0.359 Z_{\text{effective}}}{r^2}$$

where  $Z_{\text{effective}}$  = Effective nuclear charge at periphery of element A.

r = radius of the element A in Å.

In general, the electronegativity values are high for smallest elements and low for bigger atoms.

The electronegativity values of representative elements on the pauling scale are given in the following table:

Group →	1 IA	2 <b>IIA</b>	13 IIIA	14 IVA	15 VA	16 <b>VIA</b>	17 <b>VIIA</b>	
I period	Н							1
	2.1							-
II period	Li	Be	В	C	N	О	F	
	1.0	1.5	2.0	2.5	3.0	3.5	4.0	
III period	Na	Mg	Al	Si	P	, , <b>S</b>	Cl	
*	0.9	1.2	1.5	1.8	2.1	2.5	3.0	
IV period	K	Ca	Ga	Ge	As	Se	Br	
	0.8	1.0	1.6	1.8	2.0	2.4	2.8	
V period	Rb	Sr	In	Sn	Sb	Te	I	. 4
	0.8	1.0	1.7	1.8	1.9	2.01	2.5	ses
VI period	Cs	Ba	Tl	Pb	Bi	Po	Αt	rea
- •	0.7	0.9	1.8	1.9	1.9	1.76	2.2	Decreases
						$\longrightarrow$ Inc	reases	

In a period from left to right, the value of electronegativity increases while in a group from top to bottom, the value of electronegativity decreases.

The electronegativity of any given element is not constant but is dependent on the following factors:

(i) State of hybridization: For example, in the case of carbon, electronegativity decreases from sp state to  $sp^3$  state.

$$sp > sp^2 > sp^3$$
 electronegativity decreases

(ii) Oxidation state of the element: With increase of oxidation state, electronegativity increases. Fe<sup>3+</sup> (EN = 1.96) has higher electronegativity than Fe<sup>2+</sup> (EN = 1.83).

### Importance of Electronegativity

The following predictions can be made from values of electronegativity:

- (i) Nature of the bond between two atoms can be predicted by the electronegativity difference of the two atoms.
- (a) When difference  $X_A X_B = 0$ , i.e.,  $X_A = X_B$ , the bond is purely covalent. For example,  $H_2$ ,  $Cl_2$ ,  $O_2$  and  $N_2$  molecules are purely covalent and non-polar.
- (b) The difference  $X_A X_B$  is small, *i.e.*,  $X_A > X_B$ , the bond is polar covalent.
- (c) The difference  $X_A X_B$  is 1.9, the bond is 50% covalent and 50% ionic.
- (d) The difference  $X_A X_B$  is very high, the bond is more ionic and less covalent. The molecule will be represented in such case as  $BA(B^+A^-)$ .

Percentage ionic character may be calculated as:

Percentage of ionic character

$$=16(X_A - X_B) + 3.5(X_A - X_B)^2$$

where  $X_A$  and  $X_B$  represent electronegativity of bonded atoms A and B.

This relation was given by A.L. Allred (1961).

(ii) The elements having low values of electronegativity are metals while the elements having high values of

electronegativity are non-metals. Fluorine with highest electronegativity is the most non-metallic and caesium with lowest electronegativity is the most metallic element of the periodic table.

(iii)  $(X_O - X_A)$  difference predicts the nature of the oxides formed by the element A.  $X_O$  is electronegativity of oxygen.

 $X_O - X_A$  is large, the oxide shows basic nature (e.g., Na<sub>2</sub>O).  $X_O - X_A$  is small, the oxide shows acidic nature (e.g., SO<sub>2</sub>).

## Difference between Electron Gain Enthalpy and Electronegativity

Electron Gain Enthalpy	Electronegativity
1. It is the tendency of an isolated atom to attract electron.	It is the tendency of an atom in a combined state, i.e., in a molecule
	to attract the shared pair of electrons.
<ol><li>It can be measured experi- mentally.</li></ol>	It is a relative number and cannot be determined experimentally.
<ol><li>Its units are electron volts per atom or kilojoules per mole or kilocalories per mole.</li></ol>	It has no units but merely a number.
<ol> <li>It is a constant quantity for a particular element.</li> </ol>	Electronegativity of an element is not constant. It depends on a number of factors such as hybri- dised state, oxidation state, etc.
5. Its periodicity is not regular in a period or a group.	

# 1.17 SOME OTHER PROPERTIES IN WHICH PERIODICITY IS OBSERVED

(i) Atomic volume: Atomic volume increases in a group from top to bottom. The increase is due to the increase in the number of energy shells.

In a period from left to right, atomic volume varies cyclically, i.e., it decreases at first for some elements, becomes minimum in the middle and then increases. The following two factors explain this trend:

- (a) Atomic radii decrease due to increase of nuclear charge.
- (b) The number of valency electrons increases in a period. As to accommodate all the valency electrons, the volume increases. These two factors oppose each other. The effect of first factor is more on the left hand side and that of the second factor is more on the right hand side.

The maximum value of atomic volume (87) is observed in the case of francium (last member of alkali group).

(ii) Density: The density of the elements in solid state varies periodically with their atomic numbers. At first, the

density increases gradually in a period and becomes maximum somewhere for the central members and then starts decreasing afterwards gradually.

Li	Вe	В	С	N	0	F
0.5	1.8	2.3	2.2		-	
Na	Mg	Al	Si	P	S	Cl
1.0	1.7	2.7	2.3	1.8	2.1	-
K					Se	Br
0.9					4.8	3.1
Rb	*		•		Te	. I
1.5					6.2	4.9
Cs						
1.9						

In solids, osmium has the highest density (22.6) and in liquids, Hg has the highest density (13.6).

(iii) Melting and boiling points: The melting points of the elements exhibit some periodicity with rise of atomic number. It is observed that elements with low values of atomic volumes have high melting points while elements with high values of atomic volumes have low melting points. In general, melting points of elements in any period at first increase and become maximum somewhere in the centre and thereafter begins to decrease. The melting points of the elements of second and third periods are given in the table:

The boiling points of the elements also show similar trends, however, the regularities are not striking as noted in the melting points. The boiling points of the elements of third period are given below:

In moving down the group, the melting and boiling points do show regular gradation, however, the pattern of variation is different in different groups. For example, in alkali group, the melting and boiling points decrease in moving from top to bottom but among halogens, there is increase in moving from top to bottom.

Element	Li	Na	K	Rb	Cs
M.pt.(K)	454	370.8	335	312	302
B.pt.(K)	1609	1165	1063	973	943
Element	F	Cl	Br	I	
M.pt.(K)	53	172	266	386	
B.pt.(K)	85	238	332	456	

Tungsten has the maximum melting point (3683K) amongst metals and carbon has the highest melting point (4000K) amongst non-metals. Helium has the lowest melting point (3K). The metals Cs, Ga and Hg are known in liquid state at 303K.

### Periodicity in Chemical Properties

#### (I) VALENCY

The combining capacity of an element is termed the valency. The valency of an element is linked with the number of electrons present in the outermost energy shell of the atom. The electrons present in the outermost shell are, therefore, termed as Valence electrons.

In the case of representative elements, the valency is generally equal to either the number of valence electrons or equal to eight minus number of valence electrons. However, the transition elements show variable valency involving valence electrons and d electrons of the penultimate energy shell. The common valence of transition metals are either 2 or 3.

Variation in a period: In the case of representative elements, the number of valence electrons increases from 1 to 8 from left to right in a period.

Group	1	2	13	14	15	16	17	18
Number of valence electron	1 ns	2	3	4	5	6	7	. 8
Valence on hydrogen scale	1	2	3	4	3	2	1	0
Valence on oxygen scale	1	2	3	4	5	6	7	. 0

On hydrogen scale, the valency increases from 1 to 4 and then decreases from 4 to 0, while on oxygen scale, it increases from 1 to 7.

Variation in a group: In a group, all the elements have same number of valence electrons and hence, all the elements show same valency. For example, the elements of group 1 (alkali metals) show monovalency while the elements of group 2 (alkaline earth metals) show divalency.

### (II) NATURE OF OXIDES

In a period, the nature of the oxides varies from basic to acidic as stated earlier.

In a group, basic nature increases or acidic nature decreases. Oxides of the metals are generally basic and oxides

of the non-metals are acidic. The oxides of the metalloids are amphoteric. The oxides of Al, Zn, Sn, As and Sb are amphoteric. We can summarise that as the electronegativity of element increases, acidic character of oxides increases.

When an element forms a number of oxides, the acidic nature increases as the percentage of oxygen increases.

$N_2O$	Neutral	$P_2O_3$	يو ا		MnO	Basic
NO 🔍	Neutral	P <sub>2</sub> O <sub>4</sub>	attn ses	nature ases	$Mn_2O_3$	Basic
$N_2O_3$	S. Cure	$P_2O_5$	ic na reas	natu	$MnO_2$	Neutral
$ \begin{array}{c} N_2O_3\\NO_2 \end{array} $	nai	** .	ig i	di di	$MnO_3$	Acidic
$N_2O_5$	ומוכ מכת	,	[ ▼	Acidic	$Mn_2O_7$	Acidic
	Ac			1		

CO,  $N_2O$ , NO and  $H_2O$  are neutral oxides. The oxides  $CO_2$ ,  $N_2O_5$ ,  $P_2O_3$ ,  $P_2O_5$ ,  $SO_2$ ,  $SO_3$ ,  $Cl_2O_7$ , etc., are called acid anhydrides as these combine with water to form oxyacids.

$$CO_2 \longrightarrow H_2CO_3$$
  $P_2O_3 \longrightarrow H_3PO_3$   
 $SO_3 \longrightarrow H_2SO_4$   $N_2O_5 \longrightarrow HNO_3$   
 $P_2O_5 \longrightarrow H_3PO_4$   $Cl_2O_7 \longrightarrow HClO_4$   
 $N_2O_3 \longrightarrow HNO_2$   $SO_2 \longrightarrow H_2SO_3$ 

### (III) NATURE OF OXY-ACIDS

VII group HClO<sub>4</sub>

In a period, the strength of the oxy-acids formed by non-metals increases from left to right.

II period 
$$\xrightarrow{\text{H}_3\text{BO}_3}$$
  $\xrightarrow{\text{H}_2\text{CO}_3}$   $\xrightarrow{\text{HNO}_3}$  Strength increases

III period  $\xrightarrow{\text{H}_2\text{SiO}_3}$   $\xrightarrow{\text{H}_3\text{PO}_4}$   $\xrightarrow{\text{H}_2\text{SO}_4}$   $\xrightarrow{\text{HCIO}_4}$  Strength increases

In a group, the strength of the pxy-acids of non-metals decreases.

V group  $\xrightarrow{\text{HNO}_3}$   $\xrightarrow{\text{H}_3\text{PO}_4}$   $\xrightarrow{\text{H}_3\text{AsO}_4}$  Strength decreases

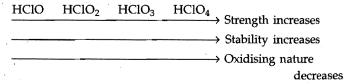

If a non-metal forms a number of oxy-acids, the strength increases with the increase of percentage of oxygen.

HBrO<sub>4</sub>

HIO<sub>4</sub>
Strength decreases

Sulphur forms two oxy-acids  $H_2SO_3$  and  $H_2SO_4$ . $H_2SO_4$  is stronger acid than  $H_2SO_3$ .

Chlorine forms a number of oxy-acids:

Greater is the oxidation state of central atom; more will be the acidic strength.

### (IV) NATURE OF HYDRIDES

The nature of the hydrides changes from basic to acidic in a period from left to right.

$NH_3$	$H_2O$	HF
Weak base	Neutral	Weak acid
$PH_3$	$H_2S$	HCl .
Very weak base	Weak acid	Strong acid

In a group, the acidic nature of the hydrides of non-metals increases. The reducing nature also increases but stability decreases from top to bottom.

HF HCl HBr HI	Strength of the acid increases
	Stability decreases
	Reducing nature increases

## (V) ANOMALOUS BEHAVIOUR OF THE ELEMENTS OF SECOND PERIOD

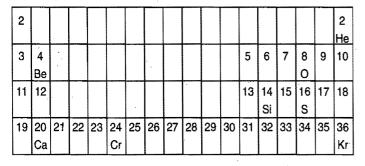

It has been observed that in the case of representative elements, the first element in each group, *i.e.*, lithium in the first group, beryllium in the second group and boron to fluorine in the groups 13 to 17, differ in many respects from the other members of their respective groups. The anomalous behaviour of the first member of each group is attributed to following reasons:

- (a) small atomic radius of the atom and ionic radius of its ion.
  - (b) high electronegativity.
  - (c) non-availability of *d*-orbitals in their valence shell.
- (d) tendency to form multiple bonds by carbon, nitrogen and oxygen.
  - (e) high charge/radius ratio.

The abnormal properties will be discussed in detail in respective groups.

## SOME SOLVED PROBLEMS

**Problem 1.** The diagram given below is a part of the periodic table. Study the table and answer the questions that follow:

- (i) Name two elements in the same group of the periodic table.
- (ii) Name a transition metal.
- (iii) Name an element whose oxide is basic.
- (iv) Name an element whose oxide has a very low melting point.
- (v) Name an element which reacts vigorously with water.
- (vi) Name an element which forms a colourless solid chloride  $XCl_2$ , where X = the element.
  - (vii) Name the element which is gaseous at room temperature.
  - (viii) Name a metallic element which has a high melting point.
- (ix) Name two elements which would react with each other to form a single compound.
- (x) Give the atomic number of an element which is an alkali metal.
- (xi) How many atoms of element-35 can combine with an atom of element-20?
  - (xii) Give the atomic number of an element which is inert.

### Solution:

- (i) The elements placed vertically one below another belong to the same subgroup. Thus, Be and Ca belong to the same subgroup.
- (ii) First transition series starts from element-21 and ends at element-30. Thus, chromium-24 is a transition metal.
- (iii) The oxides formed by the elements on left hand side of the periodic table are basic. Thus, calcium forms basic oxide.
- (iv) Sulphur forms a gaseous oxide whose melting point is low.
- (v) Alkali and alkaline earth metals react vigorously with water. Thus, calcium reacts vigorously with water.
- (vi) Calcium belongs to second group. It shows divalency and forms solid chloride of the type XCl<sub>2</sub>.
- (vii) Oxygen is known in gaseous state at room temperature.
- (viii) Transition metals have high melting points. Thus, chromium possesses high melting point.
  - (ix) Be and oxygen react together to form one oxide, BeO.

- (x) Alkali metals belong to first group. Thus, elements with atomic number 3, 11 and 19 are alkali metals.
- (xi) The element-35 is a halogen, its valency is one and the valency of element-20 (calcium) is two. Thus, one atom of element-20 combines with two atoms of element-35.
  - (xii) The atomic number of an inert gas is 36 (Kr).
- **Problem 2.** Among the elements with atomic numbers 9, 12 and 36, identify by atomic number of an element which is:
  - (a) highly electronegative
  - (b) an inert gas
  - (c) highly electropositive and give reasons for your choice.

### Solution:

The electronic configuration of the elements with atomic numbers 9, 12 and 36 are:

Atomic number 9; 2, 7

Atomic number 12; 2, 8, 2

Atomic number 36; 2, 8, 18, 8

The element with atomic number 9 can accept one more electron to have 8 electrons in the outermost orbit, thus it is an electronegative element.

The element with atomic number 12 loses two electrons to acquire inert gas configuration, thus it is electropositive in nature.

The element with atomic number 36 has 8 electrons in the outermost orbit, hence it has no tendency either to lose or accept electrons. Thus, it is an inert gas.

**Problem 3.** Two elements A and B have atomic number 16 and 19, respectively.

- (i) Write down the electronic configurations of A and B in terms of s, p, d and f.
  - (ii) Which element belongs to s-block of modern periodic table?
  - (iii) Which element belongs to p-block?
  - (iv) Which element is a powerful reducing agent?
- (v) Write down the formula of compound formed between A and B.

### Solution:

- (i)  $A = 1s^2, 2s^2 2p^6, 3s^2 3p^4$  (six electrons in valency shell).  $B = 1s^2, 2s^2 2p^6, 3s^2 3p^6, 4s^1$  (one electron in valency shell).
- (ii) B belongs to s-block as the last electron is accommodated on ns.
- (iii) A belongs to p-block as the last electron is accommodated on np.
- (iv) *B* has a tendency to lose valency electron easily, thus it acts as a powerful reducing agent.
- (v) The valency of B is 1 and that of A is 2. Thus, the formula of the compound formed is  $B_2A$ .

**Problem 4.** An element A has an atomic number 11.

- (i) Represent its electronic configuration.
- (ii) To which group of periodic table does it belong?

(iii) What is its valency?

(iv) Write the formula of its oxide.

#### Solution:

(i) Electronic configuration =  $1s^2$ ,  $2s^2 2p^6$ ,  $3s^1$ .

(ii) As one electron is present in the outermost energy shell, it belongs to first group of the periodic table.

(iii) Its valency is 1.

(iv) The formula of its oxide is  $A_2^{\circ}$ O.

Problem 5. Name the groups and periods of the elements having atomic number 18 and 26. What are the possible valencies of the above elements? [M.L.N.R. 1990]

#### Solution:

Electronic configurations of the elements are:

(A) At. no. 18

2, 8, 8

 $3s^{2} 3p$ 

(B) At. no. 26

2, 8, 8 + 6, 2

 $3d^6$ ,  $4s^2$ 

A belongs to third period and zero group.

B belongs to fourth period and eighth group.

*A* is an inert gas, its valency is zero while *B* is a transition metal. It can show variable valency. Its possible valencies are 2, 3 and 6.

**Problem 6.** The first ionisation energy of carbon atom is greater than that of boron atom, whereas reverse is true for the second ionisation energy. Explain.

#### Solution:

The electronic configurations of carbon and boron are as follows:

$$C: 1s^2, 2s^2 2p_x^1 2p_y^1 ; B: 1s^2, 2s^2 2p_x^1$$

Due to higher nuclear charge in carbon, the force of attraction towards valency electron is more in carbon atom and hence the first ionisation energy is greater than boron atom. After loss of one electron, the monovalent cations have the configurations as follows:

$$B^+: 1s^2, 2s^2 \; ; \; C^+: 1s^2, 2s^2 \; 2p_x^{\; 1}$$

The  $B^+$  configuration is a stable one and hence the removal of electron is difficult in comparison to  $C^+$ . Hence, second ionisation potential of boron is higher than carbon.

**Problem 7.** The formation of  $F^-(g)$  from F(g) is exothermic whereas that of  $O^{2-}(g)$  from O(g) is endothermic. Explain.

### Solution:

The addition of an electron to a neutral atom is an exoergic process.

$$F + e \longrightarrow F^- + \text{energy}$$
  
O +  $e \longrightarrow O^- + \text{energy}$  ...(i)

The addition of second electron to a monovalent anion  $O^-$ , as to make it  $O^{2-}$  is difficult because both have the same charge and experience a lot of repulsion. Thus, the addition of an electron to  $O^-$  requires energy to overcome the force of repulsion.

$$O^- + e + \text{energy} \longrightarrow O^{2-}$$
 ...(ii)

The energy absorbed in (ii) step is more than the energy released in the (i) step. Hence, the formation of  $O^{2-}$  from O is endothermic in nature.

**Problem 8.** (a) Why chlorine has higher negative electron gain enthalpy than F?

- (b) Why N has higher 1st ionisation enthalpy than O-atom?
- (c) Why Mg has higher 1st ionisation enthalpy than Al-atom?

#### Solution:

- (a) The size of fluorine atom is small and thus electron density is high. This resists the addition of electron, hence electron gain enthalpy of fluorine is less.
- (b) The electronic configurations of nitrogen and oxygen are as follows:

$$N: 1s^2, 2s^2 2p_x^1 2p_y^1 2p_z^1$$

O: 
$$1s^2$$
,  $2s^2 2p_x^2 2p_y^1 2p_z^1$ 

In N, *p*-orbitals are half filled and hence, its structure is stable. It requires more energy to remove an electron. Hence, the IE of nitrogen is higher than oxygen atom which has a less stable structure.

(c) The electronic configurations of Mg and Al are as follows:

$$Mg: 1s^2, 2s^2 2p^6, 3s^2$$

Al: 
$$1s^2$$
,  $2s^2$   $2p^6$ ,  $3s^2$   $3p^1$ 

It is difficult to remove an electron from 3s in comparison to 3p (3s paired and 3p singly occupied). Hence, IE of Mg is higher than Al.

**Problem 9.** The elements with atomic numbers 117 and 120 are yet to be discovered. In which family/group would you place these elements when discovered? Give their expected electronic configurations of the outermost shells and IUPAC names.

### Solution:

Atomic number	Name	Symbol	Electronic configuration	Group/family
117	Ununseptium	Uus	$7s^27p^5$	17/Halogen
120	Unbinilium	Ubn	8s <sup>2</sup>	2nd/Alkaline earth metals

**Problem 10.** Which of the following species will have the largest and smallest size?

$$Mg, Mg^{2+}, Al, Al^{3+}$$

Solution:

Mg and Al, both belong to same period.

Mg Al

Atomic number

Atomic size decreases from left to right across the period. Thus, Mg atom is larger in size than Al atom.

Cation is smaller than its neutral atom.  $Mg^{2+}$  ion is smaller than Mg atom and  $Al^{3+}$  ion is smaller than Al atom. Thus,

Al3+ ion is smallest and Mg atom is largest in size among the given species.

**Problem 11.** Arrange the following in order of increasing radii:

(i) 
$$I, I^+, I^-$$

(i) 
$$I, I^+, I^-$$
 (ii)  $C, N, Si, P$  (iii)  $O^{2-}, F^-, Ne, Mg^{2+}$  (iv)  $Fe, Fe^{2+}, Fe^{3+}$ 

### Solution:

(i)  $I^+ < I < I^-$ 

$$z/e$$
  $\frac{53}{52} \frac{53}{53} \frac{53}{54}$   $z/e$  decreases, hence size increases.

- (ii) N < C < P < Si
- (a) Effective nuclear charge in nitrogen is higher than in carbon, hence N < C.
- (b) Effective nuclear charge in phosphorus is higher than in silicon, hence P < Si.
- (c) C and Si both belong to same

C 
$$1s^2$$
,  $2s^22p^2$  (Two orbits)  
Si  $1s^2$ ,  $2s^22p^6$ ,  $3s^23p^2$  (Three orbits) C < Si

(iii) 
$$Mg^{2+} < Ne < F^- < O^{2-}$$

$$z/e \frac{12}{10} \frac{10}{10} \frac{9}{10} \frac{8}{10} z/e$$
 decreases, hence size increases.

(iv) 
$$Fe^{3+} < Fe^{2+} < Fe$$

$$z/e$$
  $\frac{26}{23}$   $\frac{26}{24}$   $\frac{26}{26}$   $z/e$  decreases, hence size increases.

Problem 12. Give the formula of a species that will be isoelectronic with the following atoms or ions:

(i) 
$$Ar$$
 (ii)  $F^-$  (iii)  $K^+$  (iv)  $Sr^{2+}$ 

### Solution:

Isoelectronic species are those which have same number of electrons.

- (i) Ar has 18 electrons. Therefore, the species P<sup>3-</sup>, S<sup>2-</sup>, Cl<sup>-</sup>, K<sup>+</sup>, Ca<sup>2+</sup>, etc., are isoelectronic to Ar.
- (ii)  $F^-$  has 10 electrons. Therefore, the species  $N^{3-}$ , O<sup>2-</sup>, Ne, Na<sup>+</sup>, Mg<sup>2+</sup>, etc., are isoelectronic to F<sup>-</sup>.
- (iii) K<sup>+</sup> has 18 electrons. Therefore, the species P<sup>3-</sup>, S<sup>2-</sup>, Cl<sup>-</sup> , Ar,  $Ca^{2+}$ , etc., are isoelectronic to  $K^+$ . (iv)  $Sr^{2+}$  has 36 electrons. Therefore, the species  $Br^-$ , Kr,
- Rb<sup>+</sup>, etc., are isoelectronic to Sr<sup>2+</sup>.

### **Problem 13.** Answer the following:

- (i) How many elements can be accommodated in the present set up of the long form of periodic table?
  - (ii) What are superheavy elements?
- (iii) What would be IUPAC names and symbols with atomic numbers 126, 134 and 150?

### Solution:

(i) There are seven periods in the present long form of periodic table. In the last period 7s, 5f, 6d and 6p orbitals are to be filled, i.e., it can accommodate 32 electrons corresponding to 32 elements. Upto the end of sixth period 86 elements have been accommodated. Thus, the present long form of periodic table can accommodate 86 + 32 = 118elements.

- (ii) Elements with atomic number higher than 100 having high densities are called superheavy elements.
- (iii) The names and symbols of the elements with atomic numbers 126, 134 and 150 are:

Z	Name	Symbol
126	Unbihexium	Ubh
134	Untriquadium	Utq
150	Unpentnilium	Upn

**Problem 14.** Which of the elements Na, Mg, Si and P would have the greatest difference between the first and second ionisation enthalpies? Explain.

#### Solution:

Among these elements, sodium is an alkali metal and has the electronic configuration,  $1s^2$ ,  $2s^2$   $2p^6$ ,  $3s^1$ . Due to the presence of only one electron in the valence shell the first ionisation enthalpy is very low. After the removal of this electron, the Na<sup>+</sup> ion has inert gas configuration, i.e., 1s<sup>2</sup>, 2s<sup>2</sup>  $2p^6$ . To remove the electron from this configuration, very high energy is required. Therefore, the second ionisation enthalpy is expected to be very high. Consequently, the difference between first and second ionisation enthalpies would be greatest in sodium atom.

Problem 15. The ionisation enthalpy of lithium is 520 kJmol<sup>-1</sup>.Calculate the amount of energy required to convert 140 mg of lithium atoms in gaseous state into Li+ ion.

### Solution:

Mass of lithium = 140 mg  
= 
$$140 \times 10^{-3}$$
 g  
=  $14 \times 10^{-2}$  g

No. of moles of lithium = 
$$\frac{14 \times 10^{-2}}{7}$$
  
=  $2 \times 10^{-2}$  mole

Energy required to convert  $2 \times 10^{-2}$  mole atoms of lithium into Li<sup>+</sup> ions =  $520 \times 2 \times 10^{-2} = 10.4 \text{ kJ}$ 

**Problem 16.** The amount of energy when million atoms of iodine are completely converted into I ions in the vapour state according to the equation,

$$I_{(g)} + e \longrightarrow I_{(g)}^- \text{ is } 4.9 \times 10^{-13} \text{ J.}$$

Calculate the electron gain enthalpy of iodine in terms of  $kI \text{ mol}^{-1}$  and eV per atom.

### Solution:

The electron gain enthalpy of iodine is equal to the energy released when 1 mole of iodine atoms in vapour state are converted into I- ions

$$= \frac{4.9 \times 10^{-13} \times 6.023 \times 10^{23}}{10^6} = 29.5 \times 10^4 \text{ J} = 295 \text{ kJ}$$

Thus electron gain enthalpy of iodine =  $-295 \text{ kJ mol}^{-1}$ We know that 1 eV per atom =  $96.49 \text{ kJ mol}^{-1}$ 

:. Electron gain enthalpy of iodine in eV per atom

$$= -\frac{295}{96.49} = -3.06$$

**Problem 17.** Assign the position of the element having outer electronic configuration

(i)  $ns^2np^4$  for n=3

(ii)  $(n-1)d^2ns^2$  for n=4

(iii)  $(n-2)f^{7}(n-1)d^{1}ns^{2}$  for n=6

in the periodic table.

### Solution:

- (i) The element belongs to 3rd period (n = 3) and group 16 (10 + 2 + 4 = 16).
- (ii) The element belongs to 4th period and group 4(2 + 2 = 4).
- (iii) The element belongs to 6th period and group 3. It is a member of lanthanide series and placed with lanthanum.

**Problem 18.** The first and second ionisation enthalpies (kJ mol<sup>-1</sup>) of three elements I, II and III are given below:

	I	II	III
$\Delta_i H_1$	403	·5 <b>49</b>	1142
$\Delta_i H_2$	2640	1060	2080

Identify the element which is likely to be:

- (a) non-metal (b) an alkali metal
- (c) an alkaline earth metal.

#### Solution:

- (a) Element (III) is a non-metal because its  $\Delta_i H_1$  is highest among the three.
- (b) Element (I) is an alkali metal as its first ionisation enthalpy is lowest and second ionisation enthalpy is very high.
- (c) Element (II) is an alkaline earth metal because its first ionisation enthalpy is near to enthalpy of element (I) and second ionisation enthalpy is not very high.

**Problem 19.** How would you justify the presence of 18 elements in the 5th period of the periodic table?

### Solution:

Each period in the periodic table starts with the filling of a principal energy shell, *i.e.*, 5th period begins with the filling of 5s-orbital. Each period is completed by filling of *np*-orbitals, *i.e.*, 5th period is completed when 5p-orbitals attain 6 electrons. Between 5s and 5p-orbitals, 4d-orbitals are also filled as their energies are higher than 5s and lower than 5p-orbitals. Therefore, in fifth period the electrons can be filled only in 5s, 4d and 5p-orbitals, *i.e.*, 9 orbitals are filled accommodating 18 electrons. Hence, 5th period has 18 elements.

**Problem 20.** How would you react to the statement that electronegativity of N on Pauling scale is 3.0 in all the nitrogen compounds?

### Solution:

The statement that electronegativity of N on Pauling scale

is 3.0 in all nitrogen compounds is not correct as electronegativity of any atom is not a constant quantity. It varies with state of hybridization and the oxidation state of the element.

Problem 21. Answer the following:

- (a) Why do elements in a group show similar chemical properties?
- (b) Alkali metals have very high second ionisation enthalpy values. Why?

#### Solution:

- (a) In a group, all the elements have same number of electrons in the valence shell and the chemical properties mainly depend on the valence electrons. Therefore, the elements belonging to the same group show similar chemical properties.
- (b) The general electronic configuration of alkali metals is  $ns^1$ . By losing this electron, they acquire the configuration of the nearest noble gas element. It is a stable configuration and to remove the electron from this configuration is difficult, *i.e.*, requires a large amount of energy. Therefore, the second ionisation enthalpy values of alkali metals are high.

**Problem 22.** In terms of period and group, where would you locate the element with Z = 113? Give the IUPAC name and symbol of the element.

#### Solution:

The last member of 6th period is radon (Z = 86). In 7th period, 7s, 5f, 6d and 7p subshells are filled. The maximum capacity of these subshells is 2, 14, 10 and 6 respectively.

Atomic number difference with radon is = 113 - 86

Thus, the electronic configuration of the element, Z = 113, is

$$7s^2 5f^{14} 6d^{10} 7p^1$$

It, therefore, belongs to 7th period and group 13 of the periodic table. Its IUPAC name is Ununtrium and symbol is Uut.

Problem 23. What are the main factors due to which the ionisation enthalpy of the main group elements tend to decrease down the group?

#### Solution:

The ionisation enthalpy of the elements decreases down the group due to following two factors :

- (i) There is increase in the number of main energy shell in moving from element to element, *i.e.*, atomic size increases gradually at each succeeding element, thereby the force of attraction of the nucleus towards valence electrons decreases.
- (ii) There is increase in the magnitude of the screening effect on account of increase in the inner electrons from one member to another and thus, the force of attraction of the nucleus towards valence electrons decreases and hence, the ionisation enthalpy decreases.

## **SUMMARY AND IMPORTANT POINTS TO REMEMBER**

- Mendeleev's periodic table was based on atomic masses of the elements. When Mendeleev presented the periodic table, only 63 elements were known. He left 29 places in the table for unknown elements.
- 2. Modern Mendeleev periodic table is based on atomic numbers of the elements. The modern periodic law is:

"The physical and chemical properties of the elements are periodic function of their atomic numbers."

The horizontal row in the periodic table is called a **period** and vertical column is called a **group**. There are seven periods and nine groups in the modern Mendeleev periodic table.

3. The long or extended form of periodic table consists of seven periods and eighteen vertical columns (groups or families). The elements in a period have same number of energy shells, i.e., principal quantum number (n). These are numbered 1 to 7.

1st period	1 <i>s</i>	orbital filled	2 elements
2nd period	2s2p	orbitals filled	8 elements
3rd period	3s3p	orbitals filled	8 elements
4th period	4s3d4p	orbitals filled	18 elements
5th period	5s4d5p	orbitals filled	18 elements
6th period	6s4f5d6p	orbitals filled	32 elements
7th period	7s5f6d7p	orbitals filled	32 elements
	Total		*118 elements

At present 117 elements are known.

In a vertical column (group), the elements have similar valence shell electronic configuration and therefore exhibit similar chemical properties.

4. There are four blocks of elements: s-, p-, d- and f-blocks depending on the orbital which gets the last electron. The general electronic configuration of these blocks are:

s-block: [Noble gas] $ns^1$  or 2. However, hydrogen has  $1s^1$  configuration.

p-block : [Noble gas] $ns^2np^{1-6}$ 

d-block: [Noble gas]  $(n-1)d^{1-10}ns^1$  or 2

f-block: [Noble gas]  $(n-2)f^{1-14}(n-1)d^{0 \text{ or } 1}ns^2$ 

s-block elements occupy IA(1) and IIA(2) groups, i.e., extreme left portion of the periodic table.

*p*-block elements occupy IIIA(13), IVA(14), VA(15), VIA(16), VIIA(17) and VIIIA(18) groups, *i.e.*, right portion of the periodic table.

**d-block elements** occupy IIIB(3), IVB(4), VB(5), VIB(6), VIIB(7), VIIIB(8,9 and 10), IB(11) and IIB(12) groups, *i.e.*, central portion of the periodic table. There are four *d*-block series, *i.e.*, 3*d* series, 4*d* series, 5*d* series and 6*d* series, each consisting of ten elements, *i.e.*, in all, forty *d*-block elements are present in periodic table.

f-block elements are accommodated in two horizontal rows below the main periodic table, each row consists of 14

elements, i.e., 28 f-block elements are present in periodic table. The elements in first row are termed 4f-elements or rare earths or lanthanides while the elements of second row are termed 5f-elements or actinides.

- 5. The elements are broadly divided into three types:
  - (i) **Metals** comprise more than 78% of the known elements. s-block, d-block and f-block elements are metals. The higher members of p-block are also metals.
  - (ii) Non-metals are less than twenty. (C, N, P, O, S, Se, H, F, Cl, Br, I, He, Ne, Ar, Kr, Xe, Rn and Uuo are non-metals)
  - (iii) Elements which lie in the border line between metals and non-metals are called semimetals or metalloids. B, Si, Ge, As, Sb, Te, Po and At are regarded metalloids.
- 6. IUPAC has given a new scheme for assigning a temporary name to the newly discovered elements. The name is derived directly from the atomic number of the element. However, IUPAC has accepted the following names of the elements from atomic numbers 104 to 110.

Rutherfordium (Rf), Dubnium (Db), Seaborgium (Sg),
104 105 106

Bohrium (Bh), Hassium (Hs), Meitnerium (Mt),
107 108 109

Darmstadtium (Ds)

110

The temporary names of the elements discovered recently are:

Unununium (Uuu),

111

Ununtrium (Uut),

113

Ununquadium (Uuq),

114

Ununpentium (Uup),

115

Ununoctium (Uuo)

Ununhexium (Uuh),

116

Ununoctium (Uuo)

7. The recurrence of similar properties of the elements after certain definite intervals when the elements are arranged in the order of increasing atomic numbers in the periodic table is termed **periodicity**. The cause of periodicity is the repetition of similar electronic configuration of the atom in the valence shell after certain definite intervals. These definite intervals are 2, 8, 8, 18, 18 and 32.

Periodicity is observed in a number of properties which are directly or indirectly linked with electronic configuration.

- (i) Effective nuclear charge increases across each period.
- (ii) Atomic radii generally decrease across the periods.
- (iii) Atomic radii generally increase on moving from top to bottom in the groups.
- (iv) Atomic radius is of three types:

- (a) Covalent radius: It is half of the distance between the centres of the nuclei of two similar atoms joined by a single covalent bond. This is generally used for non-metals.
- (b) Crystal or metallic radius: It is half of the internuclear distance between two nearest atoms in the metallic lattice. It is generally used for metals.
- (c) van der Waals' radius: It is half of the internuclear distance between two nearest atoms belonging to two adjacent molecules in solid state.

van der Waals' radius > Metallic radius > Covalent radius

(for an atom)

- (v) Cations are generally smaller than anions.
- (vi) Cations are smaller and anions are larger than neutral atoms of the elements.

Cation < Neutral atom < Anion size size size

- (vii) Elements of 2nd and 3rd transition series belonging to same vertical columns are similar in size and properties due to lanthanide contraction.
- (viii) The first element is each group of the representative elements shows abnormal properties, i.e., differs from other elements of the group because of much smaller size of the atom.
  - (ix) The ions having same number of electrons but different nuclear charge are called isoelectronic ions.
     Examples,
    - (a)  $N^{3-}$ ,  $O^{2-}$ ,  $F^-$ ,  $Na^+$ ,  $Mg^{2+}$ ,  $Al^{3+}$
    - (b) P<sup>3-</sup>, S<sup>2-</sup>, Cl<sup>-</sup>, K<sup>+</sup>, Ca<sup>2+</sup>, Sc<sup>3+</sup>

In isoelectronic ions, the size decreases if z/e increases, *i.e.*, greater the nuclear charge, smaller is the size of the ion.

- (x) The energy required to remove the most loosely held electron from the gaseous isolated atom is termed ionisation enthalpy.
- (xi) Ionisation enthalpy values generally increase across the periods.
- (xii) Ionisation enthalpy values generally decrease down the group.
- (xiii) Removal of electron from filled and half filled shells requires higher energy. For example, the ionisation enthalpy of nitrogen is higher than oxygen. Be, Mg and noble gases have high values.

The following trend is observed in the first ionisation enthalpy of the elements of second and third periods. Second period Li < Be > B < C < N > O < F < Ne

or Li < B < Be < C < O < N < F < Ne

Third period Na < Mg > Al < Si < P > S < Cl < Ar or Na < Al < Mg < Si < S < P < Cl < Ar

- (xiv) Metals have low ionisation enthalpy values while nonmetals have high ionisation enthalpy values.
- (xv) Successive ionisation enthalpies of an atom have higher values.

 $IE_I < IE_{II} < IE_{III} \dots$ 

The largest jump in between first ionisation enthalpy and second ionisation enthalpy is in the case of alkali metals as  $ns^1$  configurations change into inert gas configurations.

The largest jump in between second ionisation enthalpy and third ionisation enthalpy is in the case of alkaline earth metals.

- (xvi) The enthalpy change taking place when an electron is added to an isolated gaseous atom of the element is called electron gain enthalpy. The first electron gain enthalpy of most of the elements is negative as energy is released in the process but the values are positive or near zero in case of the atoms having stable configuration such as Be, Mg, N, noble gases, etc.
- (xvii) Electron gain enthalpy becomes more negative from left to right in a period and less negative from top to bottom in a group.
- (xviii) Successive electron gain enthalpies are always positive.
- (xix) The elements with higher ionisation enthalpy have higher negative electron gain enthalpy.
- (xx) Electronegativity is the tendency of an atom to attract the shared pair of electrons towards itself in a bond.
- (xxi) Electronegativity increases across the periods and decreases down the groups.
- (xxii) Metals have low electronegativities and non-metals have high electronegativities.
- (xxiii) Metallic character decreases across the periods and increases down the group.
- (xxiv) Valency of an element belonging to s- and p-block (except noble gases) is either equal to the number of valence electrons or eight minus number of valence electrons.
- (xxv) The reducing nature of the elements decreases across the period while oxidising nature increases.
- (xxvi) The basic character of the oxides decreases while the acidic character increases in moving from left to right in a period.

### SOME IMPORTANT FACTS ABOUT ELEMENTS

- (i) Bromine is a non-metal which is liquid at room temperature.
- (ii) Mercury is the only metal that is liquid at room temperature.
- (iii) Gallium (m.pt. 29.8°C), caesium (m.pt. 28.5°C) and francium (m.pt. 27°C) are metals having low melting points.
- (iv) Tungsten (W) has the highest melting point (3380°C) among metals.
- (v) Carbon has the highest melting point (4100°C) among non-metals.
- (vi) Oxygen is the most abundant element on the earth.
- (vii) Aluminium is the most abundant metal.
- (viii) Iron is the most abundant transition metal.

- (ix) Highest density is shown by osmium (22.59 g cm<sup>-3</sup>) or iridium (22.61 g cm<sup>-3</sup>).
- (x) Lithium is the lightest metal. Its density is  $0.54 \text{ g cm}^{-3}$ .
- (xi) Silver is the best conductor of electricity.
- (xii) Diamond (carbon) is the hardest natural substance.
- (xiii) Francium has the highest atomic volume.
- (xiv) Boron has the lowest atomic volume.
- (xv) The most abundant gas in atmosphere is nitrogen.
- (xvi) Fluorine is the most electronegative element.
- (xvii) Chlorine has the maximum negative electron gain enthalpy.
- (xviii) Helium has the maximum ionisation enthalpy.
- (xix) Caesium or francium has the lowest ionisation enthalpy.
- (xx) Helium and francium are smallest and largest atoms respectively.
- (xxi) H and I ions are the smallest and largest anions respectively.
- (xxii) H<sup>+</sup> and Cs<sup>+</sup> ions are the smallest and largest cations respectively.
- (xxiii) Caesium is the most electropositive element.
- (xxiv) Element kept in water is phosphorus, P<sub>4</sub> (white or yellow).
- (xxv) Elements kept in kerosene oil are Na, K, Rb, Cs, etc.
- (xxvi) Iodine is the element which sublimes.
- (xxvii) Hydrogen is the most abundant element in the universe.
- (xxviii) Only ozone is the coloured gas with garlic smell.
- (xxix) Metalloids have electronegativity values closer to 2.0.
- (xxx) First synthetic (i.e., man-made) element is technetium (At. no. 43).
- (xxxi) Most poisonous metal-Plutonium.
- (xxxii) Rarest element in earth's crust-Astatine.
- (xxxiii) The elements coming after uranium are called transuranic elements. The elements with Z=104-116, and 118 are called transactinides or superheavy elements. All these elements are synthetic, *i.e.*, manmade elements. These are radioactive elements and not found in nature.
- (xxxiv) The elements ruthenium (Ru), germanium (Ge), polonium (Po), francium (Fr) and americium (Am) were named in honour of the countries named Ruthenia (Russia), Germany, Poland, France and America, respectively.

The Swedish town of Ytterby has the distinction of having four elements named after it. These elements are : erbium (Er), ytterbium (Yb), yttrium (Y) and terbium (Tb). An element has been named californium (Cf) after an American state california. Few elements have been named after some famous scientists/people but none of scientist/people discovered the element named after them. These elements are :

- 1. Samarium (Sm)
  2. Gadolinium (Gd)
  3. Curium (Cm)
  4. Einsteinium (Es)
  5. Fermium (Fm)
  6. Mendelevium (Md)
  7. Nobelium (No)
  8. Lawrencium (Lr)
  9. Rutherfordium (Rf)
  10. Seaborgium (Sg)
  11. Bohrium (Bh)
  12. Meitnerium (Mt)
- 13. Röntgenium (Rg)

The following elements have been named after planets and stars.

- 1. Mercury (Hg) 2. Uranium (U)
  3. Neptunium (Np) 4. Plutonium (Pu)
  5. Titanium (Ti) 6. Zirconium (Zr)
- 7. Cerium (Ce)
- (xxxv) The members of the actinide series are radioactive and majority of them are not found in nature.
- (xxxvi) The element rutherfordium (Rf, 104) is also called Kurchatovium (Ku) and element dubnium (Db, 105) is also called hahnium.
- (xxxvii) Promethium (Pm, 61) a member of lanthanide series is not found in nature. It is a synthetic element.
- (xxxviii) Special names are given to the members of these groups in periodic table.

Group 1	or	ΙA	Alkali metals
Group 2	or	IIA	Alkaline earth metals
Group 15	or	VA	Pnictogens
Group 16	or	VIA	Chalcogens
Group 17	or	VIIA	Halogens
Group 18	or	VIIIA	Inert or noble gases
· · ·		(zero)	
Group 11	or	IB	Coinage metals

- (xxxix) Element having maximum number of isotopes—Sn (10 isotopes)
  - (xL) Least conductor among metals Pb (Lead)
  - (xLi) Heaviest naturally occurring element <sup>238</sup><sub>92</sub>U
  - (xLii) Liquid radioactive element -- Fr
- (xLiii) Element with highest tensile stress B
- (xLiv) Number of gaseous elements in the periodic table = 12  $(H_2, He, N_2, O_2, F_2, Cl_2, Ne, Ar, Xe, Kr, Rn and Uno)$
- (xLv) Most malleable metal Au
- (xLvi) Carbon has the maximum tendency for catenation.
- (xLvii) Out of 117 known elements, 90 are found in nature. These are from atomic numbers 1 to 92 with the exception of technetium (<sub>43</sub>Tc-a transition element) and promethium (<sub>61</sub>Pm-a member of lanthanide series). Traces of two posturanic elements neptunium (At. No. 93) and plutonium (At. No. 94) are found in nature in pitchblende ore.

# -•••- PRACTICE PROBLEMS -•••-

### Subjective Type Questions

- 1. Answer the following:
  - (a) Name the scientist who presented 'Law of octave'.
  - (b) Name the scientist who presented modified periodic law
  - (c) What is the basis for modern Mendeleev's periodic table and long form of periodic table?
  - (d) Name the anomalous pairs.
  - (e) Name the pairs showing a diagonal relationship.
  - (f) What are inner-transition elements?
  - (g) How many elements are present in each of the 3d, 4d and 5d-series?
  - (h) Which is the longest period in the long form of periodic table?
  - (i) Which is the shortest period in the long form of periodic table?
  - (j) How many incomplete periods are there in the long form of periodic table?
  - (k) Write the general electronic configuration of *d*-block elements.
  - (l) Write the general electronic configuration of *f*-block elements.
  - (m) Which element has the highest ionisation enthalpy value?
  - (n) Which element has the highest negative electron gain enthalpy value?
  - (o) Which element has the highest electronegativity?
  - (p) For what type of ions the ionic radius is less than the atomic radius?
  - (q) What are the units of ionisation enthalpy or electron gain enthalpy?
  - (r) Name the species (atoms or ions) having same number of electrons.
  - (s) Name three elements that exist in liquid state.
  - (t) How many more elements are to be discovered to complete the last period of the periodic table?
  - (u) How many metals and non-metals are known?
  - (v) Name the extreme left and extreme right groups of the extended form of the periodic table.
  - (w) What name is given to the elements belonging to third period of Mendeleev's periodic table?
  - (x) How many inner-transition elements are known?
- 2. Arrange the following in increasing order of the property indicated:
  - (i) F, Cl, Br and I (electron gain enthalpy) [I.I.T. 1993]
  - (ii)  $Mg^{2+}$ ,  $O^{2-}$ ,  $Na^{+}$ ,  $F^{-}$  and  $N^{3-}$  (ionic size) [I.I.T. 1991]
  - (iii) Cl, S<sup>2-</sup>, Ca<sup>2+</sup> and Ar (size)
  - (iv) Mg, Al, Si and Na (ionisation enthalpy)
  - (v) Br+, Br and Br- (size)
  - (vi) Pb, Pb<sup>2+</sup> and Pb<sup>4+</sup> (size)
  - (vii) HCl, HF, HI and HBr (acid strength)

- (viii) I<sub>2</sub>, F<sub>2</sub>, Br<sub>2</sub> and Cl<sub>2</sub> (reactivity)
  - (ix) Li, Be and B (ionisation enthalpy)
  - (x) Li, Na, K, Rb and Cs (hydrated radii)
  - (xi) SiO<sub>2</sub>, P<sub>2</sub>O<sub>5</sub>, SO<sub>3</sub> and Cl<sub>2</sub>O<sub>7</sub> (acidic nature)
- (xii) F, Cl, Br and I (electronegativity)
- (xiii) Na, Cu and Zn (electropositive character)
- (xiv) Na, Al, Fe and Pb (density)
- (xv) C, N, O and F (2nd ionisation enthalpy)
- 3. With reference to periodic table, indicate:
  - (a) an element that is in group IIIA and third period.
  - (b) an element with an atomic number greater than 16 and chemically similar to the element with atomic number 10.
  - (c) first transition element of fourth period.
  - (d) the inert gases placed in the 2nd and 5th period.
  - (e) the group which accommodates lanthanides and actinides.
  - (f) the group all members of which are metals.
  - (g) position of most electropositive element.
  - (h) position of most electronegative element.
  - (i) the group to which most abundant element belongs.
  - (j) the groups of s-block elements.
- 4. (a) Group the following elements (atomic numbers given) into various blocks noted below:
  - 12, 19, 17, 25, 31, 42, 54, 23, 38
  - (i) s-block (ii) p-block (iii) d-block
  - (b) Which of the following are transition elements? K, Mn, Ca, Cs, Fe, Cu, Pb
  - (c) In how many blocks have the elements of long form of periodic table been divided? Name them.
  - (d) The electronic configurations of some of the elements are given below:
    - $(A) \ 1s^2, \ 2s^2 \ 2p^6, \ 3s^2 \qquad (B) \ 1s^2, \ 2s^2 \ 2p^6 \qquad (C) \ 1s^2, \ 2s^2 \ 2p^3$
    - (D)  $1s^2$ ,  $2s^2$   $2p^6$ ,  $3s^1$  (E)  $1s^2$ ,  $2s^2$   $2p^5$
    - (i) Name the elements.
    - (ii) Which of these has low ionisation enthalpy?
    - (iii) Which is a halogen?
    - (iv) Which is an alkali metal?
    - (v) Which is an inert gas?
- (a) From among the elements, choose the following:
   Cl, Br, F, O, Al, C, Li, Cs and Xe
  - (i) the element with highest electron gain enthalpy.
  - (ii) the element with lowest ionisation enthalpy.
  - (iii) the element whose oxide is amphoteric.
  - (iv) the element which has smallest radius.
  - (v) the element whose atom has 6 electrons in the outermost shell.
  - (vi) the element which belongs to zero group.
  - (vii) the element which forms largest number of compounds.
  - (viii) the element which shows diagonal relationship with Mg.

- (ix) the element which is in liquid state under ordinary atmospheric conditions.
- (b) The elements Na, Mg, Al, Si, P, S, Cl and Ar are arranged in the periodic table in the increasing order of their atomic numbers.
  - (i) Which element is the most electronegative?
  - (ii) Which element is the most electropositive?
  - (iii) Which element is the least reactive?
  - (iv) Which elements are gases at room temperature?
  - (v) Which element is the most abundant metal?
  - (vi) Which element is the strongest oxidising agent?
  - (vii) Which element has the electronic configuration?  $1s^2$ ,  $2s^2$   $2p^6$ ,  $3s^2$   $3p_x^1$   $3p_y^1$   $3p_z^1$
  - (viii) Which element shows +6 oxidation state?
- (c) Pick up from the elements Na, Cl, Si and Ar.
  - (i) the element with highest ionisation enthalpy.
  - (ii) the element with highest electron gain enthalpy.
  - (iii) the element with smallest size.
  - (iv) the element with largest radius.
  - (v) the element with lowest ionisation enthalpy.
- (d) A, B and C are the elements of a short period of a periodic table containing one, two and three electrons in their outermost shell, respectively.

Arrange A, B and C in the increasing order of:

- (i) their ionisation enthalpy
- (ii) basic character of their oxides
- (iii) covalent character in their chlorides and
- (iv) melting points of their chlorides.
- 6. (a) Give the electronic configuration of third alkali metal.
  - (b) Give the electronic configuration of fifth element of first transition series.
  - (c) Give the electronic configuration of ninth element of first transition series.
  - (d) Give the names and atomic numbers of the first and last members of the lanthanide series.
  - (e) Give the names and atomic numbers of the first and last members of the actinide series.

#### 7. Answer the following:

- (a) Name of the groups of elements classified as *s-*, *p-* and *d-*blocks.
- (b) In terms of electronic configuration, what the elements of a given period and a group have in common?
- (c) Name the groups whose elements are called representative elements.
- (d) Write the general electronic configuration of s-, p-, d- and f-block elements.

#### 8. Explain:

- (a) Mg<sup>2+</sup> ion is smaller than O<sup>2-</sup> ion although both have same electronic configuration.
- (b) Why nitrogen has slightly positive electron gain enthalpy?
- (c) Sulphur has more negative electron gain enthalpy than oxygen.
- (d) In a period of normal elements, which element has lowest ionisation enthalpy and which element has highest enthalpy?

- 9. The element 119 has not been discovered. What would be IUPAC name and symbol for this element? On the basis of the periodic table, predict the electronic configuration of this element and also the formula of its most stable chloride and oxide.
- 10. Predict the formulae of stable binary compounds that would be formed by the following pairs of elements:
  - (a) element 114 and fluorine
  - (b) element 120 and oxygen.
- 11. Write short notes on:
  - (i) Döbereiner's triads
  - (ii) Law of octaves
  - (iii) Lother Meyer's curve
  - (iv) The periodic law
  - (v) Groups and periods in modern Mendeleev's periodic table
  - (vi) Groups and periods in extended form of periodic table
  - (vii) Representative elements
  - (viii) Transition elements
  - (ix) Lanthanides
  - (x) Actinides
  - (xi) Defects of Mendeleev's periodic table
  - (xii) Merits of extended form of periodic table
  - (xiii) Isoelectronic species
  - (xiv) Screening effect
  - (xv) Effective nuclear charge
  - (xvi) Ionisation enthalpy
  - (xvii) Electron gain enthalpy
  - (xviii) Electronegativity
  - (xix) Covalent radii
  - (xx) Ionic radii

### 12. Explain the following:

(i) There are only 14 lanthanides and only 14 actinides.[Hint: In lanthanides and actinides, the differentiating

int: In lanthanides and actinides, the differentiating electron enters to (n-2)f-subshell. The maximum capacity of f-subshell is of 14 electrons. Thus, there are only 14 lanthanides  $(4f^{1-14})$  and only 14 actinides  $(5f^{1-14})$ .]

(ii) Why argon (at. mass 39.94) has been placed before potassium (at. mass 39.10) in the periodic table?

[M.L.N.R. 1990]

- [Hint: In modern periodic table, elements have been placed in order of their increasing atomic numbers.

  The atomic number of argon is 18 and that of potassium is 19. Thus, argon has been placed before potassium.]
- (iii) 3d, 4d and 5d series consists of 10 elements each.
  - [Hint: In 3d, 4d and 5d series, the differentiating electron enters to (n-1)d-subshell. The maximum capacity of d-subshell is of 10 electrons. Thus, there are 10 elements each in 3d, 4d and 5d series  $[(n-1)d^{1-10}]$ .]
- (iv) There are 2, 8 and 8 elements in first, second and third periods of periodic table respectively.
  - [Hint: In first period 1s is completed. Its capacity is of two electrons. In second period 2s 2p and in third period 3s 3p are completed. The capacity of these shells is of 8 electrons each. Thus, 2, 8 and 8

elements are present in first, second and third periods respectively.]

(v) Why f-block elements are so called?

[Hint: The differentiating electron enters to (n-2)f-subshell.]

(vi) Why zero group elements are inert?

[Hint: Zero group elements are inert because they have completely filled outermost shells. Neither they have a tendency to lose or gain or share electron/ electrons with other elements.]

(vii) The radius of a cation is lesser than atom while that of an anion is greater than the atom.

[Hint: In a cation, the nuclear charge acts on lesser number of electrons and thus, the electron cloud contracts. Hence, the net result is decrease in size. In an anion, the nuclear charge acts on larger number of electrons and thus, the electron cloud expands. Hence, the net result is increase in size. This can also be explained on the basis of z/e ratio. In cation z/e ratio increases, hence size decreases while in an anion z/e ratio decreases and so the size increases.]

(viii) Why the second ionisation enthalpy of an element is higher than the first?

> [Hint: The electrostatic attraction increases in unipositive ion than in a neutral atom.]

(ix) First ionisation enthalpy of nitrogen is higher than the first ionisation enthalpy of oxygen.

[Hint: Nitrogen has stable configuration as p-orbitals are half filled.  $1s^2$ ,  $2s^2$   $2p^1_x$   $2p^1_y$   $2p^1_z$ . Hence, more energy is required to remove an electron.]

(x) Why are the electron gain enthalpies of halogens so

[Hint: The electron is easily accommodated as halogens acquire inert gas configuration after gaining the electron.]

(xi) Why noble gases have positive electron gain enthal-

[Hint: Noble gases have a stable electronic configuration. Hence, it is difficult to add the electron resulting in positive electron gain enthalpy.]

(xii) Why most of the compounds of the transition elements are coloured?

[Hint: The ions contain unpaired d-electrons.]

(xiii) Why the atomic radii of 5d transition elements is same as 4d transition elements?

> [Hint: The increase in size that arises due to period change is almost compensated by lanthanide contraction.]

(xiv) Chlorine can be converted into chloride ion easily as compared to fluoride ion from fluorine.

> [Hint: Chlorine has higher value of electron gain enthalpy as compared to fluorine.]

(xv) s-block elements are very active.

[Hint: s-block elements have low ionisation enthalpies and thus, easily form cations.]

(xvi) Why Be and Mg atoms do not impart colour in a

[Hint: Be and Mg atoms are comparatively smaller and their ionisation energies are very high. Hence, their electrons are not excited by the energy of the flame to higher energy state. Therefore, these elements do not give any colour in flame.]

(xvii) Why is potassium a strongly electropositive element? [Hint: The ionisation potential of potassium is low. Hence,

it can lose an electron easily. Therefore, it is strongly electropositive in nature.]

(xviii) Why alkali metals do not form dipositive ions?

[Hint: The alkali metals after loss of one electron achieve stable configuration of inert gases. The removal of second electron requires very high energy, hence, alkali metals do not form dipositive ions.]

13. How do the following properties vary in a period and in a group of periodic table?

(a) Covalent radii

(b) Ionic radii

(c) Ionisation enthalpy

(d) Electron gain enthalpy

(e) Electronegativity

(f) Metallic and non-metallic

14. Write down the main characteristics of:

(a) s-block elements

(b) p-block elements

(c) d-block elements

(d) f-block elements

15. Calculate the electronegativity of fluorine from the following data:

 $E_{H-H} = 104.2 \text{ kcal mol}^{-1}$ ,  $E_{H-F} = 134.6 \text{ kcal mol}^{-1}$ ,

 $E_{F-F} = 36.6 \text{ kcal mol}^{-1},$   $X_{H} = 2.1.$  [M.L.N.R. 1996]

Solution: Let the electronegativity of fluorine be X<sub>F</sub>. Applying Pauling equation,

$$X_{\rm F} - X_{\rm H} = 0.208 \left[ E_{\rm H - F} - \frac{1}{2} \left( E_{\rm F - F} + E_{\rm H - H} \right) \right]^{\frac{1}{2}}$$

In this equation, dissociation energies are taken in kcal mol<sup>-1</sup>.

$$X_{\rm F} - 2.1 = 0.208 \left[ 134.6 - \frac{1}{2} \left( 104.2 + 36.6 \right) \right]^{\frac{1}{2}} = 3.76$$

16. Calculate the electronegativity of carbon from the following

 $E_{H-H} = 104.2 \text{ kcal mol}^{-1}$ ,  $E_{C-C} = 83.1 \text{ kcal mol}^{-1}$ ,

 $E_{C-H} = 98.8 \text{ kcal mol}^{-1}, X_H = 2.1.$ 

Solution:

Let the electronegativity of carbon be XC. Applying Pauling equation,

$$X_{C} - X_{H} = 0.208 [E_{C-H} - \frac{1}{2} (E_{C-C} + E_{H-H})]^{\frac{1}{2}}$$

$$X_{C} - 2.1 = 0.208 [98.8 - \frac{1}{2} (83.1 + 104.2)]^{\frac{1}{2}}$$

$$X_{C} = 2.5$$

17. Ionisation enthalpy and electron gain enthalpy of fluorine are 17.42 and 3.45 eV respectively. Calculate the electronegativity of fluorine.

Solution:

According to Mulliken equation,

 $X = \frac{1E + Eg}{5.6}$  when both IE and Eg are taken in eV.

$$X_{\mathbf{F}} = \frac{17.42 + 3.45}{5.6} = 3.726$$

18. The electron gain enthalpy of chlorine is 3.7 eV. How much energy in kcal is released when 2g of chlorine is completely converted to Cl ion in a gaseous state?  $(1 \text{ eV} = 23.06 \text{ kcal mol}^{-1})$ 

Solution:

$$Cl + e \longrightarrow Cl^{-} + 3.7 \text{ eV}$$
  
35.5  $3.7 \times 23.06 \text{ kcal}$ 

:. Energy released for conversion of 2g gaseous chlorine into CI ions

$$= \frac{3.7 \times 23.06}{35.5} \times 2 = 4.8 \text{ kcal}$$

Calculate the electronegativity of silicon using Allred-Rochow method. Covalent radius of silicon is 1.175 Å. Solution:

Allred-Rochow equation is,

$$X = 0.359 \frac{Z_{eff}}{r^2} + 0.744$$

 $X = 0.359 \; \frac{Z_{\it eff}}{r^2} + 0.744$  ( $Z_{\it eff}$  is calculated on the basis of Slater's rules taking all the electrons.)

Electronic configuration of Si is  $1s^2$ ,  $2s^2$   $2p^6$ ,  $3s^2$   $3p^2$ .

$$Z_{eff} = 14 - (0.35 \times 4 + 0.85 \times 8 + 2 \times 1) = 3.80$$
  
 $X = 0.359 \frac{3.80}{(1.175)^2} + 0.744 = 1.73$ 

The first ionisation enthalpy of Li is 5.4 eV and the electron gain enthalpy of Cl is 3.6 eV. Calculate  $\Delta H$  in kcal mol<sup>-1</sup> for the reaction,

 $Li(g) + Cl(g) \longrightarrow Li^+ + Cl^-$ 

Carried out at such low pressure that resulting ions do not combine with each other.

#### Solution:

The overall reaction is written into two partial equations.

$$\text{Li}(g) \longrightarrow \text{Li}^+ + e$$
  $\Delta E_1 = 5.4 \text{ eV}$   
 $\text{Cl}(g) + e \longrightarrow \text{Cl}^ \Delta E_2 = -3.6 \text{ eV}$ 

$$\Delta H = \Delta E_1 - \Delta E_2 = 5.4 - 3.6 = 1.8 \text{ eV}$$

 $= 1.8 \times 23.06 \text{ kcal mol}^{-1} = 41.508 \text{ kcal mol}^{-1}$ 

- Calculate the electronegativity value of chlorine on Mulliken's scale, given that IP = 13.0 eV and EA = 4.0 eV.
- 22. Find the electronegativity of lead with the help of the given values. Screening constant ( $\sigma$ ) of Pb = 76.70, atomic number of lead = 82 and covalent radius of Pb = 5.3 Å.
- The ionisation enthalpies of atoms A and B are 400 and 300 kcal mol<sup>-1</sup> respectively. The electron gain enthalpies of these atoms are 80.0 and 85.0 kcal mol<sup>-1</sup> respectively. Prove that which of the atoms has higher electronegativity?

[Hint: 
$$X_A = \frac{400 + 80}{2 \times 62.5} = 3.84$$
;  $X_B = \frac{300 + 85}{2 \times 62.5} = 3.08$ ]

Ans. A

For the gaseous reaction,

 $\rightarrow$  K<sup>+</sup> + F<sup>-</sup>,  $\Delta H$  was calculated to be 19 kcal under conditions where the cations and anions were prevented by electrostatic separation from combining with each other. The ionisation enthalpy of K is 4.3 eV. What is the electron gain enthalpy of F?

[Hint: 
$$K \longrightarrow K^+ + e$$
  $\Delta E_1 = 4.3 \text{ eV}$   
 $F + e \longrightarrow F^ \Delta E_2 = - EeV$   
 $\frac{19.0}{23.06} = \Delta E_1 - \Delta E_2 = 4.3 - E$   
 $0.82 = 4.3 - E$   
 $E = 3.481$ 

25. How many Cl atoms can you ionise in the process  $Cl \longrightarrow Cl^+ + e$  by the energy liberated for the process  $Cl + e \longrightarrow Cl^{-}$  for one Avogadro number of atoms? Given IE = 13.0 eV and Eg = 3.60 eV.

[Hint: Let n atoms be ionised.

$$6.02 \times 10^{23} \times \text{Eg} = n \times \text{IE}$$

$$n = \frac{6.02 \times 10^{23} \times 3.60}{13} = 1.667 \times 10^{23}$$
]

26. Give the name and atomic number of the inert gas atom in which the total number of d-electrons is equal to the difference in numbers of total p and s-electrons.

[Hint: Inert gas atom is krypton. Its atomic number is 36. The electronic configuration of Kr-atom is:

$$1s^2$$
,  $2s^2$   $2p^6$ ,  $3s^2$   $3p^6$   $3d^{10}$ ,  $4s^2$   $4p^6$ 

Total s-electrons = 8

Total p-electrons = 18

Difference = 18 - 8 = 10

Total d-electrons = 10 ]

### Matching Type Questions

### Match the following:

- (A) (a) Normal element
- (i) Uranium
- (b) Noble gas
- (ii) Copper
- (c) Transition element (iii) Cerium (d) Lanthanide
  - (iv) Radon
- (e) Actinide
- (v) Potassium
- (B) (a) Fluorine
- (i) Highest negative electron gain enthalpy
- - (ii) Most electropositive element
- (b) Helium (c) Chlorine
- (iii) Most electronegative element
- (d) Caesium
- (iv) Strongest reducing agent in soln.
- (e) Lithium
- (v) Highest ionisation enthalpy
- (C) (a) s-block element
- (i) Sulphur
- (b) p-block element
- (ii) Argon
- (c) d-block element
- (iii) Neptunium
- (d) f-block element
- (iv) Iron
- (e) Inert gas
- (v) Radium
- (D)
- (a) IA (i) Liquid metal
- (1) Halogen
- (b) *d*-block (ii) Liquid non-metal (2)  $3s^2$   $3p^4$ elements
- (c) Mercury (iii) Diamond
- (3)  $ns^1$
- (d) Bromine (iv) VIA group
- (4) Variable valency

- (e) Carbon
  - (v) Alkali metals
- (5) Coinage metal
- (f) Sulphur (vi) Noble metal
- (6) Amalgam
- (g) Gold
- (vii) Transition
- (7) Hardest

metals

substance

(E) (a) A reactive non-metal; the atom has a large negative electron affinity

(i) Sodium

- (b) A soft metal; the atom has low
- (ii) Antimony
- ionisation energy (c) A metalloid that forms an oxide
  - (iii) Argon
- of the formula R<sub>2</sub>O<sub>3</sub> (d) A chemically unreactive gas
- (iv) Chlorine
- (F) (a) A reactive, pale yellow gas; the atom has a large negative electron
  - (i) Oxygen
  - affinity (b) A soft metal that reacts with
- (ii) Gallium
- water to produce hydrogen (c) A metal that forms an oxide of formula  $R_2O_3$
- (iii) Barium (iv) Fluorine
- (d) A colourless gas; the atom has moderately large negative electron affinity

### Answers

Answers: Subjective Type Questions

- 1. (a) Newland; (b) Moseley; (c) Atomic numbers of elements; (d) K, Ar; Co, Ni; Te, I; Pa, Th; (e) Li, Mg; Be, Al; B, Si; (f) Lanthanides and actinides; (g) Ten; (h) Sixth; (i) First; (j) one, i.e., 7th period; (k)  $(n-1)d^{1-10} ns^{1 \text{ or } 2}$ ; (l)  $(n-2)f^{1-14} (n-1)d^{0 \text{ or } 1} ns^2$ ; (m) Helium; (n) Chlorine; (o) Fluorine; (p) Cations; (q) eV/atom or kcal/mol or kJ/mol; (r) Isoelectronic; (s)Francium, mercury and bromine; (t) 4; (u) Out of 117 elements 94 metals and 23 non-metals; (v) I or IA (alkali group), zero group, 18 (inert or noble gases); (w) Bridge elements; (x) 28.
- 2. (i) I < Br < F < CI; (ii)  $Mg^{2+} < Na^+ < F^- < O^{2-} < N^{3-}$  [Isoelectronic ions]; (iii)  $Ca^{2+} < Ar < CI^- < S^{2-}$ ; (iv) Na < AI < Mg < Si; (v)  $Br^+ < Br < Br^-$ ; (vi)  $Pb^{4+} < Pb^{2+} < Pb$ ; (vii) HF < HCI < HBr < HI; (viii)  $I_2 < Br_2 < CI_2 < F_2$ ; (ix) Li < B < Be; (xi)  $SiO_2 < P_2O_5 < SO_3 < CI_2O_7$ ; (xii) I < Br < CI < F; (xiii) Cu < Zn < Na; (xiv) Na < AI < Fe < Pb; (xv) C < N < F < O.
- (a) Al; (b) Ar; (c) Sc; (d) Ne, Xe respectively; (e) IIIB; (f) IIA;
   (g) IA group, VIth period, (h) VIIA group, 2nd period; (i) VIA group (oxygen); (j) IA and IIA groups.
- (a) (i) s-block—12, 19, 38, (ii) p-block—17, 31, 54, (iii) d-block—25, 42, 23; (b) Mn, Fe, Cu; (c) Four blocks—(i) s-block, (ii) p-block, (iii) d-block, (iv) f-block; (d) (i) (A) Mg (B) Ne (C) N (D) Na (E) F (ii) D, (iii) E, (iv) D, (v) B.
- (a) (i) Cl, (ii) Cs, (iii) Al, (iv) F, (v) O, (vi) Xe, (vii) C, (viii) Li, (ix) Br.
  - (b) (i) Cl, (ii) Na, (iii) Ar, (iv) Cl; Ar, (v) Al, (vi) Cl, (vii) P, (viii) S.

- (c) (i) Ar, (ii) Cl, (iii) Cl, (iv) Ar, (v) Na.
- (d) (i) A < C < B, (ii) C < B < A, (iii) A < B < C, (iv) C < B < A.
- **6.** (a) K $-1s^2$ ,  $2s^22p^6$ ,  $3s^23p^6$ ,  $4s^1$ 
  - (b) Mn $-1s^2$ ,  $2s^22p^6$ ,  $3s^23p^63d^5$ ,  $4s^2$
  - (c) Cu $-1s^2$ ,  $2s^22p^6$ ,  $3s^23p^63d^{10}$ ,  $4s^1$
  - (d) Ce (Z = 58), Lu (Z = 71)
  - (e) Th (Z = 90), Lr (Z = 103)
- 7. (a) s-block = groups 1, 2
  p-block = groups 13 to 18
  d-block = groups 3 to 12
  - (b) For elements in a period, the number of energy shells is equal and for elements in the group, the number of electrons in the valence shell (outermost shell) is the same.
  - (c) groups 1, 2, 13-18
     (d) s-block : ns <sup>1-2</sup>; p-block : ns<sup>2</sup>np<sup>1-6</sup>
     d-block : (n 1)d<sup>1-10</sup>ns<sup>0-2</sup>;
     f-block : (n 2)f<sup>1-14</sup>(n 1)d<sup>0-1</sup>ns<sup>2</sup>
- 8. (a) Nuclear charge in Mg<sup>2+</sup> is more than O<sup>2-</sup>.
  - (b) N has stable configuration since it has half filled 2p-orbitals.
  - (c) O has much smaller size than S. The electron density is high in oxygen and thus, addition of electron is difficult.
  - (d) Alkali metal has the lowest and noble gas has the highest ionisation enthalpy in a period.
- 9. Ununennium; 2, 8, 18, 32, 32, 18, 8, 1; MCl; M2O.
- **10.** (a) Element 114 belongs to carbon family. Hence, the formula with fluorine will be  $AF_4$ , where A represents the element 114.
  - (b) Element 120 belongs to alkaline earth metal's family. Hence, its formula of the oxide will be MO, where M represents element 120.

## ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. What is the atomic number of last member of the seventh period of the extended form of periodic table?
  - (a) 116

(b) 118

(c) 120

(d) 122

Ans. (b)

[Hint: The last member of the sixth period is radon. Its atomic number is 86. In the seventh period energy shells 7s, 5f,

6d and 7p are completed, i.e., 2 + 14 + 10 + 6 = 32electrons are to be accommodated. Thus, in the 7th period, 32 elements will be present. So, the atomic number of the last member will be 86 + 32 = 118.

- 2. An element 'X' with atomic number 114 has recently been discovered. Its IUPAC name is:
  - (a) Eka-lead
- (b) Ununfortium
- (c) Ununquadium
- (d) Bohrium

Ans. (c)

[Hint: Un - un - quad - ium] 1

3. The process requiring absorption of energy is:

(a)  $F \longrightarrow F$ (c)  $Cl \longrightarrow Cl^-$  (b)  $H \longrightarrow H^-$ (d)  $O \longrightarrow O^{2-}$ 

Ans. (d)

[Hint: Second electron gain enthalpy is an endothermic process as the second electron is added to a negatively charged particle. Energy is needed to overcome force of repulsion.]

- Which transition involves maximum amount of energy?
  - (a)  $M^-(g) \longrightarrow M(g) + e$
  - (b)  $M^{-}(g) \longrightarrow M^{+}(g) + 2e$
  - (c)  $M^+(g) \longrightarrow M^{2+}(g) + e$
  - (d)  $M^{2+}(g) \longrightarrow M^{3+}(g) + e$

Ans. (d)

[Hint: 3rd I.P. > 2nd I.P. > 1st I.P.]

- 5. Na<sup>+</sup>, Mg<sup>2+</sup>, Al<sup>3+</sup> and Si<sup>4+</sup> are isoelectronic ions. Their ionic size follows the order:
  - (a)  $Na^+ < Mg^{2+} < Al^{3+} < Si^{4+}$
  - (b)  $Na^+ < Mg^{2+} < Al^{3+} > Si^{4+}$
  - (c)  $Na^+ < Mg^{2+} > Al^{3+} > Si^{4+}$
  - (d)  $Na^+ > Mg^{2+} > Al^{3+} > Si^{4+}$

Ans. (d)

[Hint:  $\frac{z}{e}$  Na<sup>+</sup> = 1.1, Mg<sup>2+</sup> = 1.2, Al<sup>3+</sup> = 1.3 and Si<sup>4+</sup> = 1.4 As  $\frac{Z}{\rho}$  increases, size decreases.]

- 6. (i) There are four *d*-block series.
  - (ii) Total d-block elements are 40.
  - (iii) Last d-block series starts with element actinium.
  - (iv) All members of d-block series are stable elements and found in nature.

The correct statements are:

- (a) (i), (ii) and (iii)
- (b) (i) and (iii)
- (c) (i) and (iv)
- (d) All

Ans. (a)

- 7. The formula of the binary compound formed by the element with atomic number 120 and sulphur is: (b) X<sub>2</sub>S (c) XS<sub>2</sub>
  - (a) XS

Ans. (a)

[Hint: The electronic configuration of the element X with atomic number 120 is [Uuo]  $8s^2$ . Thus, it belongs to second group and its valency is 2.]

- Elements A, B, C, D and E have the following electronic configurations:
  - (A)  $1s^2$ ,  $2s^2$   $2p^1$
- (B)  $1s^2$ ,  $2s^2 2p^6$ ,  $3s^2 3p^1$
- (C)  $1s^2$ ,  $2s^2 2p^6$ ,  $3s^2 3p^3$
- (D)  $1s^2$ ,  $2s^2 2p^6$ ,  $3s^2 3p^5$
- (E)  $1s^2$ ,  $2s^2 2p^6$ ,  $3s^2 3p^6$ ,  $4s^1$

The elements which belong to the same group of the periodic table are:

- (a) (A) and (C)
- (b) (A) and (B)
- (c) (A) and (D)
- (d) (A) and (E)

Ans. (b)

- 9. In the long form of periodic table, the number of period indicates the value of:
  - (a) atomic number
  - (b) atomic mass
  - (c) principal quantum number
  - (d) azimuthal quantum number

[Hint: The serial number of the period indicates the principal quantum number (n) which is the value of the valence shell of the atoms of the elements present in that period.]

- 10. Which one of the following statements is incorrect in relation to ionisation enthalpy?
  - (a) Ionisation enthalpy increases for each successive electron
  - (b) The greater increase in ionisation enthalpy is experienced on removal of electron from core noble gas configuration
  - (c) End of valence electrons is marked by a big jump in ionisation enthalpy
  - (d) Removal of electron from orbitals bearing lower n value is easier than from an orbital having higher n value

Ans. (d)

[Hint: Removal of electron from orbitals bearing lower value of n is difficult than from the orbital having higher value of

- 11. The correct order regarding electronegativity of hybrid orbitals of carbon is: IC.B.S.E. 2006]
  - (a)  $sp < sp^2 < sp^3$
- (b)  $sp < sp^2 > sp^3$
- (c)  $sp > sp^2 < sp^3$
- (d)  $sp > sp^2 > sp^3$

[Hint: Electronegativity increases as s-character in hybrid orbital increases.]

- 12. The electronic configurations of four elements are :
  - (i) [Xe] 6s<sup>1</sup>
- (ii) [Xe]  $4f^{14}5d^16s^2$
- (iii) [Ar]  $4s^24p^5$
- (iv) [Ar]  $3d^74s^2$

Which one of the following statements about these elements is not correct?

- (a) (i) is a strong reducing agent
- (b) (ii) is a d-block element
- (c) (iii) has high negative electron gain enthalpy
- (d) (iv) shows variable oxidation state

Ans. (b)

[Hint: (ii) is a last member of lanthanide series, i.e., 4f-element.]

- 13. Which of the following ions is most unlikely to exist?
  - (a) Li

(b) Be<sup>2+</sup>

(c) B-

(d) F

Ans. (a)

[Hint: Metals are electropositive, they do not form anion.]

- **14.** The element having very high ionization enthalpy but zero electron gain enthalpy is:
  - (a) H

(b) F

(c) He

(d) Be

Ans. (c)

[Hint: Inert gases have zero electron affinity.]

- 15. The second ionization energy is maximum for :
  - (a) boron
- (b) beryllium
- (c) magnesium
- (d) aluminium

Ans. (a)

**[Hint:**  $B_5 \longrightarrow 1s^2$ ,  $2s^2$ ,  $2p^1$ 

Second electron is to be removed from completely filled s-subshell, which is difficult.]

- **16.** The radii of F,  $F^-$ , O and  $O^{2-}$  are in the order :
  - $(a) O^{2-} > F^- > F > O$
- (b)  $F^- > O^{2-} > F > O$
- (c)  $O^{2-} > O > F^- > F$
- (d)  $O^{2-} > F^{-} > O > F$

Ans. (d)

[Hint: Anions are larger than neutral atoms. Oxygen is larger than fluorine as the nuclear charge is less.]

- 17. In the sixth period, the orbitals are filled as:
  - (a) 6s 5f 6d 6p
- (b) 6s 4f 5d 6p
- (c) 5s 5p 5d 6p
- (d) 6s 6p 6d 6f

Ans. (b)

- **18.** In the periodic table, which of the following trends is correct in a period ?
  - (a) Electron affinity decreases
  - (b) Electronegative character decreases
  - (c) Electropositive character increases
  - (d) Non-metallic nature increases

Ans. (d)

- **19.** The atomic radius of elements of the following series should be nearly the same :
  - (a) Na, K, Rb, Cs
- (b) Na, Mg, Al, Si
- (c) Fe, Co, Ni, Cu
- (d) F, Cl, Br, I

Ans. (c)

[Hint: Transition metals of the same series have nearly the same atomic radius.]

- **20.** In the following, the element with the highest ionisation energy is:
  - (a) [Ne]  $3s^2 3p^1$
- (b) [Ne]  $3s^2 3p^3$
- (c) [Ne]  $3s^2 3p^2$
- (d) [Ne]  $3s^2 3p^4$

Ans. (b)

**[Hint :** [Ne]  $3s^2$   $3p^3$  is a symmetrical configuration. Thus, this atom has extra stability.]

			. · · ·	

### Set I: This set contains questions with single correct answer.

1.	The 'Law of triads' was enunciated by:	12.	The elements which occupy their positions in periodic ta	ıble
	(a) Mendeleev $\square$ (b) Newland $\square$	<u> </u>	just after the members of zero group are:	
	(c) Lother Meyer $\Box$ (d) Döbereiner $\Box$		(a) metals	
2.	The group number of an element in periodic table indicates:		(c) radioactive	
	(a) valency with respect to hydrogen	13.	An element having electronic configuration [Ar] 3d <sup>2</sup>	$4s^2$
	(b) the atomicity	!	belongs to:	
	(c) the number of electrons in the outermost shell $\Box$		(a) $d$ -block $\square$ (b) $f$ -block	
	(d) none of the above		(c) s-block	
3.	Which of the following statements is not correct about	14.	Elements belonging to same subgroup of periodic ta	able
	Lother Meyer's classification in the form of curve?		have generally the same:	
	(a) The elements present at the peaks are chemically very		(a) electronic configuration	
	active		(b) number of electrons in the outermost shell	
	(b) Alkaline earth metals are present at the descending		(c) chemical properties	
	portions of the curve $\Box$		(d) physical properties	
	(c) Halogens occupy ascending portions of the curve $\Box$	15.	The number of elements in fifth period of periodic table	e is:
	(d) The elements present in the troughs are chemically very		(a) 8	
	reactive and are known as representative elements $\square$		(c) 18	
4.	Which element was named Eka-aluminium by Mendeleev?	16.	An element which belongs to third period and fifth gre	oup
	(a) Scandium		has electronic configuration:	
	(c) Germanium $\Box$ (d) Indium $\Box$		(a) $1s^2$ , $2s^22p^6$ , $3s^2$ $3p^3$	
5.	Without looking at the periodic table, select the elements		(c) $1s^2$ , $2s^2 2p^6$ , $3s^2 3p^4 \square$ (d) none of these	
	of IIIA group of the periodic table (Atomic numbers are	17.	Which of the following is a d-block element?	
	given):		(a) Fr	
	(a) 3, 11, 19, 37		(c) Zn	
	(c) 7, 15, 31, 49	18.	d-block elements in long form of periodic table are place	ced:
6.	The transition elements have a characteristic electronic		(a) on the extreme left $\Box$ (b) on the extreme right	
	configuration which can be represented as:		(c) at the bottom $\Box$ (d) none of these	
	(a) $(n-2)s^2p^6d^{1-10}(n-1)s^2p^6ns^2$	19.	Ce (58) is a member of:	•
	(b) $(n-2)s^2p^6d^{1-10}(n-1)s^2p^6d^{1 \text{ or } 2} ns^1$		(a) s-block $\Box$ (b) $p$ -block	
	(c) $(n-1)s^2p^6d^{10} ns^2np^6nd^{1-10}$		(c) $d$ -block $\square$ (d) $f$ -block	
	(d) $(n-1)s^2p^6d^{1-10}ns^1$ or 2	20.	Which of the following is not an actinide?	
7.	The attempt for classifying elements by plotting the atomic		[D.P.M.T. 20	005]
•	masses of elements against the volumes was made by:		(a) Curium	
	(a) Döbereiner		(c) Uranium	
	(c) Lother Meyer	21.	Europium is: [D.P.M.T. 20	
8.	Who presented the law of octave?		(a) s-block $\Box$ (b) p-block	
	(a) Döbereiner		(c) $d$ -block $\square$ (d) $f$ -block	
	(c) Lother Meyer	22.	Variable valency is a general feature of:	
9.	How many elements were known when Mendeleev		(a) s-block elements	
	presented the periodic table?		(c) $d$ -block elements $\square$ (d) none of these	
	(a) 63	23.	Which one of the following ions is paramagnetic?	
	(c) 92		(a) $Ag^+$	
10.	The basis of periodic law presented by Mendeleev was:		(c) $K^+$	
	(a) valency	24.	Mark the group which has maximum number of elem-	ents
	(c) atomic number		in Mendeleev's periodic table:	-
11.	The modern Mendeleev's periodic table consists of		(a) I	
	groups:	-	(c) III	
	(a) seven	25.	Diagonal relationship in periodic table is shown	by
	(c) nine		elements of and periods :	A 14 4

	(a) I and II	l 37.	The halogens are:
	(c) III and IV	. 1:	(a) normal elements
26.	An element (X) which occurs in the second period has ar		(b) noble elements
	outer electronic configuration $s^2p^1$ -what is the formula and		(c) transition elements
	nature of its oxide?		(d) inner-transition elements
	(a) $XO_3$ , basic $\Box$ (b) $X_2O_3$ , acidic $\Box$	38.	^ ^ ·
	(c) $X_2O_3$ , basic $\Box$ (d) $XO_2$ , acidic $\Box$		ionic radii show: [C.B.S.E. (P.M.T.) 2003]
27.	An element of atomic mass 40 has 2, 8, 8, 2 as the electronic	:	(a) an increase from O <sup>2-</sup> to F <sup>-</sup> and then decrease from Na <sup>+</sup>
	configuration. Which one of the following statements	l l	to Al <sup>3+</sup>
	regarding this element is not correct?		(b) a decrease from O <sup>2-</sup> to F <sup>-</sup> and then increase from Na <sup>+</sup>
	(a) It forms an amphoteric oxide		to Al <sup>3+</sup>
	(b) It belongs to IIA group		(c) a significant increase from $O^{2-}$ to $Al^{3+}$
	(c) It belongs to IV period	1	(d) a significant decrease from $O^{2-}$ to $Al^{3+}$
	(d) It has 20 neutrons		Modern extended periodic table was given by:
28.	The most predominantly electrovalent compounds will be	1	(a) Bohr $\square$ (b) Lother Meyer $\square$
	obtained from the combination of elements belonging to		(c) Mosley
	(a) I and VII groups   (b) II and VI groups   (c)		In the modern periodic table, one of the following does not
	(c) III and V groups $\Box$ (d) none of these $\Box$		have appropriate position:
29.	Which one of the following configurations represents a		(a) inert gases
	metallic character?	'	(b) inner-transition elements
	(a) 2, 8, 2	ı	(c) transition elements
	(c) 2, 8, 7		(d) fluorine
30.	The first ionisation enthalpies of Na, Mg, Al and Si are in	l l	Which one of the following grouping represent a collection
	the order of:		of isoelectronic species? (At. numbers, $Cs = 55$ and $Br = 35$ )
	(a) Na $<$ Mg $>$ Al $<$ Si $\square$ (b) Na $>$ Mg $>$ Al $>$ Si $\square$	1	[A.I.E.E.E. 2003]
	(c) Na $<$ Mg $<$ Al $>$ Si $\square$ (d) Na $>$ Mg $>$ Al $<$ Si $\square$		(a) $N^{3-}$ , $F^{-}$ , $Na^{+}$
31.	Ionisation enthalpy of K would numerically the same as		(c) Be, $Al^{3+}$ , $Cl^{-}$
	(a) Electronegativity of K <sup>+</sup>	42.	The formation of $O_{(g)}^{2-}$ starting from $O_{(g)}$ is endothermic
	(b) Electron gain enthalpy of K <sup>+</sup>		by 639 kJ mol <sup>-1</sup> . If electron gain enthalpy of $O_{(g)}$ is -141 kJ
	(c) Electron gain enthalpy of Ar		mol <sup>-1</sup> , the second electron gain enthalpy of oxygen would
	(d) Ionisation enthalpy of Ca	.	be:
32.	The electronegativity of the following elements increases		(a) $-780 \text{ kJ mol}^{-1}$
	in the order of:		(c) + 498 kJ mol <sup>-1</sup> $\Box$ (d) - 498 kJ mol <sup>-1</sup> $\Box$
	(a) C, N, Si, P	ı	[ <b>Hint:</b> $O_{(g)} + 2e^{-} \longrightarrow O_{(g)}^{2-}$ ; $\Delta H = 639 \text{ kJ mol}^{-1}$ (i)
	(c) Si, P, C, N		$O_{(g)} + e^{-} \longrightarrow O_{(g)}^{-}$ ; $\Delta H = -141 \text{ kJ mol}^{-1}$ (ii)]
33.	The order in which the following oxides are arranged		Subtracting equation (ii) from equation (i)
	according to decreasing basic nature is:		$O_{(g)}^{-} + e^{-} \longrightarrow O_{(g)}^{2-}$ ; $\Delta H = 639 + 141 = 780 \text{ kJ mol}^{-1}$ ]
	(a) CuO, Na <sub>2</sub> O, MgO, Al <sub>2</sub> O <sub>3</sub>	43.	Which of the following elements has the maximum electron
	(b) Al <sub>2</sub> O <sub>3</sub> , MgO, CuO, Na <sub>2</sub> O		gain enthalpy?
	(c) MgO, Al <sub>2</sub> O <sub>3</sub> , CuO, Na <sub>2</sub> O		(a) oxygen
	(d) Na <sub>2</sub> O, MgO, Al <sub>2</sub> O <sub>3</sub> , CuO		(c) fluorine
34.	The difference between ions and atoms is of:	44.	The set representing the correct order of first ionisation
	(a) relative size	ı	enthalpy is: [I.I.T. (S) 2001] (a) $K > Na > Li$
	(c) presence of charge $\Box$ (d) all of these $\Box$		
35.	Na <sup>+</sup> is smaller than Na-atom because:		, ,
	(a) nucleus in each case contains different nucleons		If we go from Li to F in the second period, there would be a decrease in:
	(b) sodium atom has an electron lesser than sodium ion	'	
		.	· · ·
	(c) sodium atom has 11 electrons and sodium ion has 16	1	(c) ionisation enthalpy (d) electronegativity (17)
	electrons		The element having electronic configuration [Kr] $4d^{10}$ $4f^{14}$ , $5s^2$ $5p^6$ $5d^1$ , $6s^2$ belongs to:
	(d) the force of attraction is less in Na <sup>+</sup> than in Na-atom	'	
	than in ivaluation	ıİ	
36.	The highest valency of halogens with respect to oxygen is	- I	
	(a) 1		
	(c) 2		(a) Na < Be < B $\Box$ (b) F <sup>-</sup> < O <sup>2-</sup> < N <sup>3-</sup> $\Box$
	. , ,	İ	(c) Na < Li < K $\Box$ (d) Fe <sup>3+</sup> < Fe <sup>2+</sup> < Fe <sup>4+</sup> $\Box$

48.	In going from left to right in a period:			Lowest ionisation enthalpy in periods is shown by:
	(a) the basic nature of the oxides increases			(a) inert gases
	(b) acidic nature decreases			(c) alkali metals □ (d) alkaline earth metals □
•	(c) the basic nature of the oxides decreases		60.	Which of the following is basic?
	(d) no gradation in the nature of oxides is observed			(a) $F_2$ $\square$ (b) $Cl_2$ $\square$
49.	The elements with atomic numbers 58 to 71 are called:			(c) $Br_2$ $\Box$ (d) $I_2$ $\Box$
	(a) normal elements $\square$ (b) transition elements		61.	Strongest reducing agent among the following is:
	(c) lanthanides			(a) F
50.	An element R forms the highest oxide R <sub>2</sub> O <sub>5</sub> . R belongs	to:		(c) Br
	(a) IV group		62.	The elements with atomic numbers 10, 18, 36, 54 and 86 are
	(c) VI group			all:
51.	Transition metals are characterised by the properties exce			(a) light metals
0	(a) variable valency			(c) halogens
	(b) coloured compounds		63.	The elements on the right side of the periodic table are:
	(c) high melting and boiling points		00.	(a) non-metals
	(d) no tendency to form complexes			(c) transition elements $\Box$ (d) metalloids $\Box$
<b>E</b> 2	· -		6.1	
52.	Ionisation enthalpy in the alkali group:		04.	Which of the following atoms has the largest atomic radius?
	(a) increases from Li to Cs			(a) Cs
	(b) decreases from Li to Cs		<b>45</b>	(c) Pb
	(c) remains the same		65.	Which of the following is the weakest acid?
	(d) bears no gradation			(a) HF
53.	The ionisation enthalpy of isotopes of an element will			(c) HBr
	(a) same		66.	Electron affinity of :
	(b) different			(a) carbon is higher than oxygen
	(c) dependent on atomic masses			(b) sulphur is lesser than oxygen
	(d) dependent on the number of neutrons present in			(c) iodine is higher than bromine $\Box$
	nucleus			(d) chlorine is higher than fluorine
54.	The ionic radius of a cation is always:		67.	The correct order of relative stability of half filled and
	(a) less than atomic radius			completely filled shells is:
	(b) more than atomic radius			(a) $p^3 < d^5 < d^{10} < p^6$
	(c) equal to atomic radius			(c) $p^3 < d^{10} < d^5 < p^6$
	(d) cannot be predicted		68.	The electronic configuration of an element A is $1s^2$ , $2s^2$ $2p^5$ .
55.	The screening effect of 'd' electrons is:			The formula of substance containing only A will be:
	(a) much more than s-electrons			(a) $A \square$ (b) $A_2 \square$
	(b) equal to s-electrons			(c) $A_5$ $\square$ (d) $A_7$ $\square$
	(c) equal to p-electrons		69.	The electronic configuration of element A is $1s^2$ , $2s^2$ $2p^6$ ,
	(d) much less than s-electrons			$3s^2$ while of the element B is $1s^2$ , $2s^2$ $2p^5$ . The formula of
56.	Which of the following statements is incorrect?			the compound containing A and B will be:
	(a) Among all the elements, fluorine has the high	nest		(a) $AB$ $\square$ (b) $A_2B$ $\square$
	electron gain enthalpy		İ	(c) $AB_2$ $\square$ (d) $A_2B_6$ $\square$
	(b) Among all the elements, helium has the high	nest	70.	The valency shell of element A contains 3 electrons while
	ionisation enthalpy		İ .	the valency shell of element B contains 6 electrons. If A
	(c) Elements of groups 1, 2, 13, 14, 15, 16 and 17 are ca	lled		combines with B, the probable formula of the compound
	representative elements			formed will be:
	(d) All the <i>d</i> -block elements are metallic in nature			(a) $AB_2$ $\Box$ (b) $A_2B$ $\Box$
57.			1	(c) $A_2B_3$ $\square$ (d) $A_3B_2$ $\square$
	enthalpy?		71	Which one of the following has the highest melting point?
	(a) H		/1.	• • • • • • • • • • • • • • • • • • • •
	(c) He			(a) Na
50	The first ionisation enthalpies of four consecutive elements		72	
58.	<del>-</del> .		12.	Which one of the following is most acidic?
	present in the second period of the periodic table are		1	(a) Al <sub>2</sub> O <sub>3</sub>
	11.3, 14.5 and 13.6 eV respectively. Which one of	me	70	(c) MgO
	following is the first ionisation enthalpy of nitrogen?	1043	73.	Which of the following is an amphoteric oxide?
	[E,A,M,C,E,T, (Med.) 2	_		(a) MgO $\Box$ (b) Al <sub>2</sub> O <sub>3</sub> $\Box$ (c) SiO $\Box$ (d) PrO
	(a) 13.6			(c) $SiO_2$ $\Box$ (d) $P_2O_5$ $\Box$
	(c) 11.3		i	

74.	Which of the following is the correct statement?		ŧ.	In the series carbon, nitrogen, oxygen and fluorine, electron-
	(a) SO <sub>2</sub> is anhydride of sulphuric acid		1	egativity:
	(b) NO <sub>2</sub> is anhydride of nitric acid			(a) decreases from carbon to fluorine
	(c) Cl <sub>2</sub> O <sub>7</sub> is anhydride of perchloric acid .		1	(b) remains constant
	(d) P <sub>2</sub> O <sub>5</sub> is anhydride of orthophosphorus acid		4	(c) decreases from carbon to oxygen and then increases
75.	Which is the most acidic oxide?		1	(d) increases from carbon to fluorine
	(a) $Cl_2O$ $\square$ (b) $Cl_2O_3$		89.	Ionisation energy of nitrogen is more than oxygen because:
	(c) $Cl_2O_5$ $\Box$ (d) $Cl_2O_7$		1	(a) nucleus has more attraction for electrons
76.	Which of the following halides is not oxidised by MnO	$O_2$ ?	and the state of t	(b) half filled $p$ -orbitals are more stable $\square$
	(a) $F^-$		3	(c) nitrogen atom is small
	(c) Br		1	(d) more penetration effect
77.	Which of the following orders is correct for the rela	tive		Lanthanide contraction explains :
•	strength of the acids?			(a) density of the series
	(a) $HClO_4 > HNO_3 > H_2SO_4 > HCl$		1	(b) atomic volume of the series
	(b) $HCIO_4 > HC1 > HNO_3 > H_2SO_4$			(c) chemical activity of the series
•	(c) $HClO_4 > H_2SO_4 > HCl > HNO_3$		1	(d) size of the atoms of the series $\Box$
	(d) $HClO_4 > HNO_3 > H_2SO_4 > HCl$		91.	The outermost electronic configuration of the most electron-
78.	The most non-metallic element among the following i	s:		egative element is:
	(a) $1s^2$ , $2s^2$ $2p^6$			(a) $ns^2 np^3$
	(c) $1s^2$ , $2s^2$ $2p^4$		-	(c) $ns^2 np^5$
79.	The highest bond strength amongst the following, is of		92.	Amongst the following elements (whose electronic config-
, , , .	(a) HF			urations are given below) the one having highest ionisation
*	(c) HBr			energy is: [I.LT. 1990; .C.B.S.E.(P.M.T.) 2009]
80.	An element <i>M</i> has an atomic number 9 and atomic mass		Table and the same	(a) [Ne] $3s^2 3p^1$
	Its ion will be represented by:	, 17.		(c) [Ne] $3s^2 3p^2$
	(a) $M$ $\square$ (b) $M^{2+}$		93.	The electronic configuration of the element which is just
	(c) $M^ \square$ (d) $M^{2-}$			above the element with atomic number 43 in the same
81.				periodic group is:
٠.٠	(a) 92			(a) $1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^5$ , $4s^2$
	(c) 100			(b) $1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^5$
82.				(c) $1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^6$ , $4s^1$
Ű <b>.</b>	(a) angstrom units			(d) $1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^1$ $4p^6$
	(c) cm		94.	The statement that is not correct for the periodic classi-
83.			į	fication of elements is:
	According to law of triads the atomic mass of Na will	-	No. of Contract of	(a) The properties of elements are periodic functions of their
	(a) 23			atomic numbers
	(c) 46			(b) Non-metallic elements are lesser in number than
84.			er residence	metallic elements
	easily?			(c) The first ionisation energies of the elements along the
	(a) Li, Na, K			periods do not vary in a regular manner with the
	(c) O, S, Se		0	increase in atomic number
85.		by:		(d) For transition elements the d-subshells are filled with
	(a) alkali metals	Ó	1	electrons monotonically with increase in atomic
	(b) inert gases			number 🗆
	(c) representative elements		95.	If the atomic number of an element is 33, it will be placed
	(d) halogens		sh na na da	in the periodic table in the:
86.			Thomas Spanis	(a) first group
	group of the periodic table. They are called:		THE PERSON NAMED IN COLUMN NAM	(c) fifth group $\Box$ (d) seventh group $\Box$
	(a) alkaline earth metals □ (b) inert gases		96.	Which one of the following ions has the smallest radius?
	(c) alkali metals		i i	(a) $C^{4-}$
87.		ents	-	(c) $K^+$ $\Box$ (d) $Ca^{2+}$ $\Box$
	most electropositive element?		97.	The most electropositive element is:
	(a) [He] $2s^1$			(a) Cs
	(c) [Xe] $6s^1$	П		(c) Li

	Among the following, the element which is not liquid at	112.	Chloride of an element 'A' gives neutral solution in water.
	room temperature (30°C) is:		In the periodic table, the element 'A' belongs to:
	(a) Ga		(a) first group
	(c) Cs $\square$ (d) Br $\square$	112	(c) fifth group
99.	Which of the block of elements does belong to inert gases?	115.	of elements in the periodic table?
	(a) s-block $\Box$ (b) p-block $\Box$		(a) Lanthanum
	(c) $d$ -block $\square$ (d) $f$ -block $\square$	1	(c) Chromium
100.	Which of the following elements has the lowest ionisation	114.	An element of atomic number 29 belongs to:
	enthalpy?		(a) s-block $\Box$ (b) p-block $\Box$
	(a) Na	1	(c) $d$ -block $\Box$ (d) $f$ -block $\Box$
	(c) Mg	115.	A trend common to both groups 1 and 17 elements in the
101.	Which one of the following is smallest in size?		periodic table as atomic number increases is:
	(a) $Na^+$ $\square$ (b) $O^{2-}$ $\square$		(a) increase in oxidising nature
	(c) $N^{3-}$ $\square$ (d) $F^{-}$ $\square$	ł	(b) increase in atomic radius
102.	Which of the following has the lowest ionisation enthalpy?		(c) increase in maximum valency $\Box$
	(a) $4s^1$ $\Box$ (b) $3d^2$ $\Box$		(d) increase in reactivity with water $\Box$
	(c) $3p^6$ $\Box$ (d) $2p^6$ $\Box$	116.	Which of the following has largest radius?
103	Of the following elements, which one has the highest		(a) $O^{2-}$ $\square$ (b) $Mg^{2+}$ $\square$
100.	electronegativity?		(c) $Na^+$ $\square$ (d) $F^ \square$
	(a) I	117.	Which one is the correct order of the size of the iodine
	(c) C1		species?
104	Which of the following is the smallest cation?		(a) $I > I^+ > I^-$
101.	(a) $Na^+$		(c) $I^+ > I^- > I$
	(c) $Ca^{2+}$ $\Box$ (d) $Al^{3+}$ $\Box$	118.	Which of the following configurations represents atoms of
105			element having a large difference between first and the
105.	Among the following outermost configurations of transition metals which shows the highest oxidation state, is:		second ionisation energy?
			(a) $1s^2$ , $2s^2 2p^4$
	5 2		(c) $1s^2$ , $2s^22p^6$ , $3s^1$
106		119.	In which of the following arrangements, the order is not
100.	Which of the following ions has the lowest magnetic		according to the property indicated against it?
	moment? (a) $Cu^{2+}$ $\Box$ (b) $Ni^{2+}$ $\Box$		[A.I.E.E.E. 2005]
	2.		(a) $Al^{3+} < Mg^{2+} < Na^{+} < F$ increasing ionic size $\Box$
1.05			(b) $B < C < N < O$ increasing first ionisation enthalpy $\Box$
107.	Modern periodic table is based on the atomic number of		(c) I < Br < F < Cl increasing electron gain enthalpy
	the elements. The experiment which proved the significance	1	(with negative sign)
	of the atomic number was:		(d) Li < Na < K < Rb increasing metallic radius □
	(a) Millikan's oil drop experiment	120.	. A sudden large jump between the values of second and third
	(b) Moseley's work on X-ray spectra		ionisation energies of an element would be associated with
	(c) Bragg's work on X-ray diffraction	1	the electronic configuration:
400	(d) Discovery of X-rays by Rontgen		(a) $1s^2$ , $2s^2$ $2p^6$ , $3s^1$
108.	Which of the following pairs has both members from the		(c) $1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^2$ $\Box$ (d) $1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $\Box$
	same group of the periodic table?	121.	. In the long form of the periodic table, all the non-metals
	(a) Na, Ca		are placed with:
	(c) Ca, Cl		(a) s-block $\Box$ (b) p-block $\Box$
109.	Which of the following set of ions represents a collection	Ì	(c) $d$ -block $\square$ (d) $f$ -block $\square$
	of isoelectronic species? [A.I.E.E. 2006]	122.	. The lanthanide contraction is responsible for the fact that :
	(a) $Ba^{2+}$ , $Sr^{2+}$ , $K^+$ , $Ca^{2+}$ $\Box$ (b) $K^+$ , $Cl^-$ , $Ca^{2+}$ , $Sc^{3+}$ $\Box$	1	[A.I.E.E.E. 2005]
	(c) $N^{3-}$ , $O^{2-}$ , $F^{-}$ , $S^{2-}$ $\square$ (d) $Li^{+}$ , $Na^{+}$ , $Mg^{2+}$ , $Ca^{2+}$ $\square$		(a) Zr and Y have about the same radius
110.	Aluminium is diagonally related to:		(b) $Zr$ and $Nb$ have similar oxidation state
	(a) Li		(c) $Zr$ and $Hf$ have about the same radius
	(c) Be		(d) Zr and Zn have the same oxidation state
111.	In the sixth period of the extended form of periodic table,	123	. Of cobalt and zinc salts, which are attracted in magnetic
	the orbitals are filled as:		field?
	(a) $6s$ , $5f$ , $6d$ , $6p$		(a) Cobalt salts
	(c) be by 6d bf $\square$ (d) be 4f 5d by $\square$	1	(c) Both

124.	The electronic configuration of an element is $1s^2$ , $2s^3 3p^3$ . What is the atomic number of the element which below the above element in the periodic table?		<ul> <li>(b) The second ionisation potential of Mg is greater than the second ionisation potential of Na □</li> <li>(c) The first ionisation potential of Na is less than the first</li> </ul>
	(a) 34		ionisation potential of Mg
	(c) 33		(d) The third ionisation potential of Mg is greater than third
125.	Element X belongs to 4th period. It contains 18	and 1	ionisation potential of Al
	electrons in the penultimate and ultimate orbit.	The X	138. Element with atomic number 56 belongs to which block?
	should be:		[A.F.M.C. 2002]
	(a) normal element $\Box$ (b) transition element		(a) $s$ $\Box$ (b) $p$ $\Box$
	(c) inert gas		(c) $d$ $\Box$ (d) $f$
	(d) inner-transition element		139. Which of the following orders is wrong? [C.B.S.E. 2002]
126.	Electron gain enthalpy of X would be equal to:		(a) $NH_3 < PH_3 < AsH_3 - Acidic$
	(a) electron affinity of X		(b) Li $<$ Be $<$ B $<$ C $-$ IE <sub>1</sub>
	(b) ionisation potential of X <sup>-</sup>		(c) $Al_2O_3 < MgO < Na_2O < K_2O - Basic$
	(c) ionisation potential of X		(d) $\operatorname{Li}^+ < \operatorname{Na}^+ < \operatorname{K}^+ < \operatorname{Cs}^+$ – Ionic radius
	(d) none of the above		140. Which is true about electronegativity order of the following
127.	Element with atomic number 35 belongs to:		elements? [B.V. (Pune) 2002]
	(a) 3rd period		(a) $P > Si$ $\square$ (b) $C > N$
	(c) 5th period		(c) $C > Br$ $\Box$ (d) $Sr > Ca$
128.	Most of the man-made synthetic elements occur:		141. Eka-aluminium and Eka-silicon are known as:
	(a) in actinide series $\Box$ (b) in lanthanide series		[M.E.E.(Kerala) 2002]
	(c) in coinage metals	. 🗆	(a) gallium and germanium
	(d) in alkaline earth metals		(b) aluminium and silicon
129.	Which is the largest stable atom?	_	(c) iron and sulphur
	(a) V		(d) proton and silicon
400	(c) Al		142. Two elements whose electronegativities are 1.2 and 3.0, the
130.	Which of the following is strongest base?	_	bond formed between them would be: [P.E.T.(M.P.) 2002]
	(a) $Be(OH)_2$		(a) ionic
101	(c) Al(OH) <sub>3</sub>		. (c) coordinate $\Box$ (d) metallic $\Box$
131.	Which has largest atomic size?		143. Chloride ion and potassium ion are isoelectronic. Then:
	(a) Al		[K.C.E.T. 2002]
	(c) $Al^{3+}$ $\Box$ (d) $Al^{+}$		(a) their sizes are same
132.	Alkaline earth metals form ions of the formula:	_	(b) Cl <sup>-</sup> ion is bigger than K <sup>+</sup> ion
	(a) $M^+$		(c) K <sup>+</sup> ion is relatively bigger
100	(c) $M^{2+}$		(d) their sizes depend on other cation and anion
133.	Which one of these is basic?		144. Identify the least stable ion amongst the following:
	(a) $CO_2$		[I.I.T.(S) 2002]
104	(c) NO <sub>2</sub>		(a) Li
134.	Of cobalt and zinc salts, which are attracted in a ma	agnetic	(c) B <sup>-</sup>
	field?	_	145. Increasing order of electron gain enthalpy is:
	(a) Cobalt salts		[P.E.T.(Raj.) 2003]
105	(c) Both (a) and (b) (d) None		(a) $N < O < Cl < Al$
133.	Which of the following species has the highest electro	on gạin	(c) $Al < N < O < Cl$
	enthalpy? (a) F⁻ □ (b) O	_	146. Which of the following sets is of coinage metals?
	(a) F		[D.P.M.T. 2003]
136	Among the isoelectronic species, K <sup>+</sup> , S <sup>2-</sup> , Cl <sup>-</sup> and C		(a) Cu, Ag, Hg
150.	radii of the ions decrease as:	a uic	(c) Au, Ag, Zn
	(a) $Ca^{2+} > K^+ > C\Gamma > S^{2-}$		147. According to modern periodic law, variations in the
	(a) $Ca^{-} \times K^{-} \times C1^{-} \times S2^{-} \times K^{+} \times Ca^{2+}$		properties of elements is related to their: [A.I.E.E.E. 2003]
			(a) atomic weights $\square$ (b) nuclear weights $\square$
	(c) $S^2 > C\Gamma > K^+ > Ca^{2+}$		(c) atomic numbers □ (d) neutron-proton ratios □
105	(d) $K^+ > Ca^{2+} > S^{2-} > C\Gamma$		148. Which of the following has maximum ionisation enthalpy?
13/.	The incorrect statement among the following is:	h a <i>fi</i>	[P.M.T. (Pb.) 2003]
	(a) The first ionisation potential of Al is less than the ionisation potential of Ma		
	ionisation potential of Mg		

	· · · · · · · · · · · · · · · · · · ·	
	(a) K	158. Which of the following has lowest ionisation energy?
	(c) Mg	[C.P.M.T. 2007]
149.	The electronic configuration of transition elements is	(a) Oxygen □ (b) Nitrogen □
	exhibited by: [P.M.T. (Pb.) 2003]	(c) Fluorine $\Box$ (d) Sulphur $\Box$
	(a) $ns^1$	159. The electronic configuration of the element with maximum
	(c) $ns^2 (n-1)d^{10}$	electron affinity is: [P.E.T. (Kerala) 2008]
150.	General electronic configuration of outermost and penulti-	(a) $1s^2$ , $2s^2$ $2p^3$
	mate shell is $(n-1) s^2 (n-1) p^6 (n-1) d^x n s^2$ . If $n=4$ and	(a) $1s^2$ , $2s^2$ $2p^3$
	x = 5, then number of protons in the nucleus will be:	(e) $1s^2$ , $2s^2$ $2p^6$ , $3s^1$
	[P.E.T. (M.P.) 2003]	160. The first ionisation energy of oxygen is less than that of
	(a) > 25 $\Box$ (b) < 24 $\Box$	nitrogen. Which of the following is the correct reason for
	(c) 25	this observation? [P.E.T. (Kerala) 2008]
151.	Increasing order of density is: [P.E.T. (M.P.) 2003]	(a) Lesser effective nuclear charge of oxygen than nitrogen
	(a) Li $<$ K $<$ Na $<$ Rb $<$ Cs	
	(b) Li $<$ Na $<$ K $<$ Rb $<$ Cs	(b) Lesser atomic size of oxygen than nitrogen □
	(c) $Cs < Rb < K < Na < Li$	(c) Greater inter-electron repulsion between two electrons
	(d) $K < Li < Na < Rb < Cs$	in the same p- orbital counter balances the increase in
152.	Outer electronic configurations of K, Cu and Cr are	effective nuclear charge on moving from nitrogen to
	respectively: [B.H.U. 2003]	oxygen □
	(a) $4s^1$ , $3d^{10}$ $3d^5$ $\Box$ (b) $4s^2$ , $3d^{10}$ $3d^4$ $\Box$	(d) Greater effective nuclear charge of oxygen than nitrogen
	(c) $4s^1$ , $3d^9$ $3d^4$	
153.	Identify the correct order of the size of the following:	(e) Higher electronegativity of oxygen than nitrogen
	[C.B.S.E. 2007, 10]	161. Column I Column II
•	(a) $Ca^{2+} < K^+ < Ar < Cl^- < S^{2-}$	(A) He (i) High electron gain enthalpy (B) C1 (ii) Most electropositive element

### **Objective Questions for IIT ASPIRANTS**

1. The paramagnetic species among the following is:

- (c) Cu<sup>+</sup>
- (d)  $Fe^{3+}$
- [Hint: Paramagnetic species have at least one unpaired electron. Write the electronic configuration and observe the unpaired orbital.
  - $Na^+: 1s^2, 2s^2 2p^6$

- $Zn^{2+}$ :  $1s^2$ ,  $2s^2$   $2p^6$ ,  $3s^2$   $3p^6$   $3d^{10}$  All paired;
- $Cu^+: 1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^{10}$  All paired;
- $Fe^{3+}: 1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^5$  Unpaired orbitals]
- 2. The diamagnetic species among the following is:

- (b) Cd<sup>2+</sup>
- (c) Cr<sup>3+</sup>
- [Hint: Diamagnetic species have all paired electrons.
- $Cu^{2+}: 1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^9$  Unpaired orbital;
- $Cr^{3+}: 1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^3$  Unpaired orbitals;
- $Co^{3+}: 1s^2, 2s^2 2p^6, 3s^2 3p^6 \uparrow \downarrow \uparrow \uparrow \uparrow \uparrow \uparrow$  Unpaired orbitals;
- $Cd^{2+}: 1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^{10}, 4s^2 4p^6 4d^{10}$  All paired ]
- The correct decreasing order of electropositive character among the following elements is:

- (a) Fe > Sc > Rb > Br > Te > F > Ca
- (b) Ca > Rb > Sc > Fe > Te > F > Br
- (c) Rb > Ca > Sc > Fe > Br > Te > F
- (d) Rb > Ca > Sc > Fe > Te > Br > F

[Hint: Remember the following points:

- (i) Alkali and alkaline earth metals are most electropositive. Alkali metals are more electropositive than alkaline earth metals.
- (ii) In d-block series, the elements near alkaline earth metals are more electropositive than rest of the
- (iii) Metalloids are less electropositive than metals.
- (iv) Halogens (Non-metals) are least electropositive. In halogen group, electropositive character increases as atomic number increases.]
- 4. The correct decreasing order of atomic size among the following species is:

- (a)  $Ca^{2+} > K^+ > Ar > Cl^- > S^{2-}$  (b)  $K^+ > Ca^{2+} > Cl^- > Ar > S^{2-}$
- (c)  $S^{2-} > CI^{-} > Ar > K^{+} > Ca^{2+}$  (d)  $S^{2-} > Ar > CI^{-} > Ca^{2+} > K^{+}$
- [Hint : In isoelectronic ions, the atomic size decreases as  $\frac{z}{a}$  ratio

$$S^{2-}\frac{z}{e} = \frac{16}{18}$$
;  $CI^{-}\frac{z}{e} = \frac{17}{18}$ ;  $Ar\frac{z}{e} = \frac{18}{18}$ ;  $K^{+}\frac{z}{e} = \frac{19}{18}$ ;  $Ca^{2+}\frac{z}{e} = \frac{20}{18}$ 

- 5. If each orbital can take maximum of three electrons, the number of elements in the third period of the periodic table will be:
  - (a) 12

(b) 6 .

(c) 8

(d) 24

[Hint: In third period, 3s- and 3p-orbitals are filled. Total orbitals to be filled = one s + three p = 4. Thus, number of elements  $=4\times3$  =12.]

- The number of elements which can be accommodated in the present set-up of the long form of the periodic table is:
  - (a) 120

(b) 118

(c) 122

(d) 124

[Hint: In the present set-up, on the basis of aufbau principle and four blocks of elements, the last period, i.e., 7th period is to accommodate 32 elements  $(7s^2, 5f^{14}, 6d^{10}, 7p^6)$ . Thus, total elements can be accommodated 118 (86 up to 6th period plus 32 in the 7th period).]

- 7. What would be the atomic number of the next halogen if discovered in future?
  - (a) 115

(b) 119

(c) 117

(d) 121

[Hint: The next halogen will have  $7s^27p^5$  outer configuration. Since, the filling of 7p-orbitals will begin after 5f- and 6dorbitals, thus the atomic number of the new halogen will be 112 (up to the filling of 6d-orbitals) plus 5, i.e., 117.]

The energies of the electron in a hydrogen like ion are given

 $E_n = -(2.18 \times 10^{-18}) Z^2 \left(\frac{1}{n^2}\right)$ , where *n* is principal quantum number and Z is the atomic number of the element. The ionisation energy (in kJ mol<sup>-1</sup>) of the Li<sup>2+</sup> ion is:

- (a)  $1.18 \times 10^3$
- (b)  $118 \times 10^3$
- (c)  $0.118 \times 10^3$
- (d)  $11.8 \times 10^3$

[Hint: Ionisation energy =  $(2.18 \times 10^{-18}) Z^2 \left(\frac{1}{n^2}\right) \times N \text{ J mol}^{-1}$  where

N is the Avogadro number.

For 
$$Li^{2+} = (2.18 \times 10^{-18}) \times 3^2 (1) \times 6.02 \times 10^{23} \text{J mol}^{-1}$$

First and second ionisation energies of magnesium are 7.646 and 15.035 eV respectively. The amount of energy in kJ needed to convert all the atoms of magnesium into Mg<sup>2+</sup> ions present in 12 mg of magnesium vapours is :

[Given :  $1eV = 96.5 \text{ k} \text{[ mol}^{-1} \text{]}$ 

(a) 1.1

(c) 2.0

(d) 0.5

[Hint: Total energy needed to convert one Mg atom into Mg2+ (gas) ion =  $IE_{II} + IE_{II}$ 

$$= 22.681 \text{ eV} = 2188.6 \text{ kJ mol}^{-1}$$

12 mg of Mg =  $0.5 \times 10^{-3}$  mole]

- 10. Which of the following has highest electron gain enthalpy?
  - (A) [Ne]  $3s^2 3p^3$ ;
- (B) [Ne]  $3s^2 3p^4$
- (C) [Ne]  $3s^2 3p^5$ ;
- (D) [Ne]  $3s^2 3v^2$
- (a) (A)
- (b) (B)
- (c) (C)
- (d) (D)

[Hint: The element (C) will have highest electron gain enthalpy as it easily gains one more electron to achieve stable configuration of next inert gas.]

- 11. The element with atomic number 35 belongs to :
  - (a) d-block

(b) f-block

(c) p-block

(d) s-block

[Hint: Write the electronic configuration on the basis of aufbau

$$1s^2$$
,  $2s^2 2p^6$ ,  $3s^2 3p^6 3d^{10}$ ,  $4s^2 4p^5$ 

The last electron is accommodated on p-energy shell. ]

- 12. The electronic configurations for some neutral atoms are given below:
  - (A)  $1s^2$ ,  $2s^2 2p^6$ ,  $3s^2$

(B)  $1s^2$ ,  $2s^2 2p^6$ ,  $3s^1$ 

(C)  $1s^2$ ,  $2s^2 2p^6$ ,  $3s^2 3p^2$ 

(D)  $1s^2$ ,  $2s^2 2p^6$ ,  $3s^2 3p^3$ 

Which of these is expected to have the highest second ionisation enthalpy?

(a) (A)

(b) (B)

(c) (C)

(d) (D)

[Hint: B atom after losing outermost electron acquires noble gas configuration (stable configuration). It is difficult to remove the next electron from B+ (1s2, 2s2 2p6) ion.]

- The amount of energy released when 106 atoms of iodine in vapour state are converted to I<sup>-</sup> ions is  $4.9 \times 10^{-13}$  J. What is the electron affinity of iodine in eV per atom?

- (b) 2.5
- (c) 2.75;

[Hint: Amount of energy released for 1 mole of iodine

$$=\frac{4.9\times10^{-13}}{10^6}\times6.02\times10^{23}$$

 $= 29.5 \times 10^4 \text{ J} = 295 \text{ kJ mol}^{-1}$ 

 $1 \text{ eV per atom} = 96.3 \text{ kJ mol}^{-1}$ 

List I

14. Match the following lists and select the correct answer:

(A)	$1s^2$ , $2s^2$	$2p^6$ , $3s^2$	$3p^6, 4s^1$	(1)	d-block element
<b>(B)</b> .	$1s^2$ , $2s^2$	$2p^6, 3s^2$ 3	$3p^6$	(2)	Halogen
(C)	$1s^2$ , $2s^2$	2p <sup>6</sup> , 3s <sup>2</sup> 3	3p <sup>6</sup> 3d <sup>6</sup> , 4s <sup>2</sup>	(3)	Alkali metal
(D)	$1s^2$ , $2s^2$	$2p^{5}$		(4)	Noble gas
	Α	В	С	D	
(a)	1	2	3	4	
(b)	3	4	1	2	
(c)	1	3	2	4	
(d)	2	4	3	1	

- 15. Which of the following is the wrong statement?
  - (a) All the actinide elements are radioactive
  - (b) Alkali and alkaline earth metals are s-block elements
  - (c) Chalcogens and halogens are p-block elements
  - (d) The first member of the lanthanide series is lanthanum
- Which of the following is the correct statement?
  - (a) The second ionisation potential of an atom is always less than the first ionisation potential.
  - (b) The addition of an electron to a neutral atom is an endothermic process
  - (c) Fluorine has the maximum electronegativity

- (d) The size of the cation is always less than the size of the neutral atom
- 17. (A), (B) and (C) are elements in the third short period. Oxide of (A) is ionic, that of (B) is amphoteric and of (C) a giant molecule. (A), (B) and (C) have atomic number in the order:
  - (a) (A) < (B) < (C)
- (b) (C) < (B) < (A)
- (c) (A) < (C) < (B)
- (d) (B) < (A) < (C)

**[Hint:**  $A_c$  B and C are magnesium, aluminium and silicon. Magnesium forms ionic oxide, MgO, aluminium forms amphoteric oxide, Al<sub>2</sub>O<sub>3</sub> and silicon forms a giant molecule, SiO2.]

18. Match the List I with List II and select the correct answer:

### List I

List II

- (A) Most electronegative element
- (1) Chlorine
- (B) The element having highest electron gain enthalpy
- (2) Hydrogen
- (C) Most abundant element in the universe
- (3) Nitrogen (4) Fluorine
- (D) Most abundant gas in atmosphere В C
- 2 3 (a) 4
- 2 3 (b) 4
- (c) 4 1 2 3
- (d)
- The five successive ionisation energies of the element are 800, 2427, 3658, 25024 and 32824 kJ mol<sup>-1</sup> respectively. The number of valence electrons is:
  - (a) 3
- (b) 5

[Hint: Fourth ionisation energy abruptly increases. This shows that fourth electron is removed from inert gas core.]

- Which of the following species has the negative electron gain enthalpy?
  - (a) F<sup>-</sup>

(b) O

(c) O

(d) Na<sup>+</sup>

[Hint: Energy is released when electron is added to O but energy is absorbed in rest of the cases when electron is added.]

- 21. The ionic radius of Cr is minimum in which of the following compounds?
  - (a) CrF<sub>3</sub>
- (b) CrCl<sub>3</sub>
- (c)  $Cr_2O_3$
- (d)  $K_2CrO_4$

[Hint: Cr has maximum oxidation number (+6) in K2CrO4 and thus, has minimum ionic radius.]

- 22. Arrange Ce<sup>3+</sup>, La<sup>3+</sup>, Pm<sup>3+</sup> and Yb<sup>3+</sup> in increasing order of their size:
  - (a)  $Yb^{3+} < Pm^{3+} < Ce^{3+} < La^{3+}$
  - (b)  $Ce^{3+} < Yb^{3+} < Pm^{3+} < La^{3+}$
  - (c)  $Yb^{3+} < Pm^{3+} < La^{3+} < Ce^{3+}$ (d)  $Pm^{3+} < La^{3+} < Ce^{3+} < Yb^{3+}$

[Hint: Lanthanide contraction is observed in these ions, i.e., ionic radius decreases as atomic number increases.]

- 23. Which of the following statements related to the modern periodic table is incorrect?
  - (a) The p-block has 6 vertical columns, i.e., groups
  - (b) The *d*-block has 8 vertical columns

- (c) Each block contains a number of columns equal to the number of electrons that can occupy that subshell
- (d) The block indicates value of azimuthal quantum number (1) for the last subshell that received electrons in building up the electronic configuration.

[Hint: d-block has 10 columns.]

- 24. Following statements regarding the periodic trends of chemical reactivity of the alkali metals and the halogens are given. Which of these statements gives the correct picture?
  - (a) The reactivity decreases in the alkali metals but increases in halogens with increase in atomic number down the group
  - (b) In both the groups, the chemical reactivity decreases with increase in atomic number down the group
  - (c) In both the groups, the chemical reactivity increases with increase in atomic number down the group

- (d) In alkali group, the chemical reactivity increases but decreases in the halogens with increase in atomic number down the group
- 25. The values of electronegativity of atoms A and B are 1.20 and 4.0 respectively. The percentage ionic character of A - B bond is:
  - (a) 50.0%

(b) 72.2%

(c) 55.3%

(d) 43.0%

[Hint: % ionic character =  $16(4 - 1.2) + 3.5(4 - 1.2)^2 = 72.2$ ] The element with atomic number 118 (Uuo) has been discovered recently. Which of the following is not expected

for this element?

- (a) It is radioactive and unstable element
- (b) It is a solid at room temperature
- (c) Its ionisation enthalpy is minimum in the group
- (d) It has  $7s^27p^6$  outer shell configuration

### Auswers

## Matrix Matching Questions for IIT Aspirants

1. Match List-I with List-II:

List-I (Group/Period)\* List-II

(Element)

- (a) 7th period
- (p) Transition elements
- (b) IIIB group
- (q) Inner transition elements
- (c) IA
- (r) Hydrogen
- (d) VIIA
- (s) Halogens
- 2. Match List-I with List-II:

List-I
--------

List-II

- (a) (P + 1) > N
- (p) Al
- (b) (P + 1) = 7
- (q) Pb
- (c) (P + 1) < N
- (r) C
- (d) (P + 1) = N
- (s) Si

Here, P = Number of period.

N = Number of valence electrons.

[Hint:In p-block:

(P + 1) > N; (P + 1) < N, (P + 1) = N

respectively represent metal, non-metal and metalloid.

3. Match the atomic number in List-I, with the block in List-II and groups in List-III:

List-I	List-II	List-III
(Atomic number)	(Block)	(Group)*
·(a) 55	(p) p	(u) VIII
(b) 45	(q) f	(v) IIIB

<sup>\*</sup>Modern Mendeleev's Periodic Table

## **Assertion-Reason Type Questions**

The questions given below consist of an Assertion (A) and Reason (R). Use the following key to choose the correct answer.

- (a) If both (A) and (R) are correct and (R) is the correct explanation of the (A).
- (b) If both (A) and (R) are correct and (R) is not the correct explanation of (A).
- (c) If (A) is correct and (R) is incorrect.
- (d) If both (A) and (R) are incorrect.
- 1. (A) Each d-block series contains ten elements.
  - (R) The maximum capacity of *d*-orbitals is of ten electrons as in each series *d*-orbitals are gradually filled up.
- 2. (A) Helium and beryllium have similar outer electronic configuration  $ns^2$ .
  - (R) Both are chemically inert.

IA.LI.M.S. 199

- **3.** (A) Electron gain enthalpy of oxygen is less than that of fluorine but greater than that of nitrogen.
  - (R) Ionisation enthalpy is as follows:

N > O > F

[A.I.I.M.S. 1998]

- 4. (A) The first ionisation energy of Be is greater than that of B.
  - (R) 2p-orbital is lower in energy than 2s-orbital. [I.I.T. 2001]

- 5. (A) Cu<sup>2+</sup> is diamagnetic.
  - (R) All the orbitals present in Cu<sup>2+</sup> ion are doubly occupied.
- 6. (A) The size decreases as  $Pb > Pb^{2+} > Pb^{4+}$ .
  - (R)  $\frac{z}{e}$  increases, *i.e.*, force of attraction towards nucleus increases.
- **7.** (A) There are fourteen elements in the lanthanide series and fourteen elements in the actinide series.
  - (R) All the elements of the actinide series are radioactive.
- **8.** (A) The group 18 consists of elements which are in gaseous state under ordinary atmospheric conditions.
  - (R) All the elements of group 18 have stable configuration.
- 9. (A) First ionisation energy of nitrogen is lower than oxygen.
  - (R) Across a period effective nuclear charge decreases.

[A.I.I.M.S. 2005]

- 10. (A) F atom has a less negative electron affinity than chlorine.
  - (R) Additional electrons are repelled more effectively by 3*p* electrons in Cl atom than by 2*p* electrons in F atom.
- 11. (A) The ionic size of Mg<sup>2+</sup> is larger than Al<sup>3+</sup>.
  - (R) In isoelectronic species, greater the nuclear charge, less is the size.

<sup>\*</sup>Modern Mendeleev's Periodic Table

# THOUGHT TYPE QUESTIONS

### **THOUGHT 1**

Numerous forms of the periodic table have been devised from time to time. A modern version, which is most convenient and widely used is the long or extended form of periodic table. The aufbau principle and the electronic configuration of atoms provide a theoretical foundation for the periodic classification. The horizontal rows are called periods. There are altogether seven periods. The first period consists of 2 elements. The subsequent periods consist of 8, 8, 18, 18 and 32 elements respectively. The seventh period is incomplete and like the sixth period would have maximum of 32 elements.

Elements having similar outer electronic configurations in their atoms are grouped in vertical columns. These are referred to as groups or families. According to the recommendation of IUPAC, the groups are numbered 1 to 18 replacing the older notation of groups 0, IA, IIA, ......... VIIA, VIII, IB, ......... VII B.

Each successive period in the periodic table is associated with the filling up next higher principal energy level following aufbau sequence. The number of elements in each period is twice the number of atomic orbitals available in the energy level that is being filled. All the elements are classified into four blocks, *i.e.*, *s*-block, *p*-block, *d*-block and *f*-block depending on the type of atomic orbitals that are being filled with electrons.

1. An element belongs to group 17. It is present in third period and its atomic number is 17. What is the atomic number of the element belonging to same group and present in fifth period?

(a) 25

(b) 33

(c) 35

(d) 53

- **2.** Elements in the same vertical group of the periodic table have generally the same :
  - (a) atomic number
  - (b) electronic configuration
  - (c) atomic mass
  - (d) number of electrons in the outermost shell of their atoms
- 3. The element with atomic number 118 is likely to have the same outer shell configuration as the element with atomic number:

(a) 18

(b) 28

(c) 58

(d) 88

- **4.** What is the position of the element in the periodic **table** satisfying the electronic configuration (n-1)  $d^1$   $ns^2$  for n=4?
  - (a) 3rd period and 3rd group
  - (b) 4th period and 3rd group

- (c) 3rd period and 2nd group
- (d) 4th period and 2nd group
- 5. Elements A, B, C, D and E have the following electronic configurations:

(A)  $1s^2$ ,  $2s^2$   $2p^1$ 

(B)  $1s^2$ ,  $2s^2$   $2p^6$ ,  $3s^2$   $3p^1$ 

(C)  $1s^2$ ,  $2s^2$   $2p^6$ ,  $3s^2$   $3p^3$ 

(D)  $1s^2$ ,  $2s^2$   $2p^6$ ,  $3s^2$   $3p^5$ 

(E)  $1s^2$ ,  $2s^2$   $2p^6$ ,  $3s^2$   $3p^6$ 

Which among these will belong to same group in the periodic table ?

(a) (A) and (C)

(b) (A) and (D)

(c) (A) and (B)

(d) (A) and (E)

6. The outer electronic configuration of an element is,  $(n-2) f^7 (n-1) d^1 ns^2$ .

To which block in the long form of the periodic table does this belong?

(a) s-block

(b) p-block

(c) d-block

(d) f-block

7. The elements with atomic numbers 90 to 103 are known as:

(a) d-block elements

(b) lanthanides

(c) actinides

(d) transition elements

8. In Mendeleev's periodic table, silver belongs to IB group. The group to which silver belongs in long form of periodic table is:

(a) first

(b) eleventh

(c) tenth

(d) sixteenth

**9.** The elements in which 4f-orbitals are progressively filled are called as:

(a) lanthanides

(b) actinides

(c) transition elements

(d) chalcogens

10. If aufbau rule is not followed, Ca-20 will be placed in .....block.

(a) s-

(b) p-

(c) d-

(d) f-

[Hint: If aufbau rule is not followed, the electronic configuration of Ca-20 will be  $1s^2$ ,  $2s^2$   $2p^6$ ,  $3s^2$   $3p^6$   $3d^2$ , i.e., last electron will be accommodated on d- orbital.]

## THOUGHT 2

The minimum amount of energy required to remove the most loosely bound electron from an isolated atom in the gaseous state is known as ionisation energy or first ionisation energy or ionisation enthalpy ( $IE_1$ ) of the element. The energy required to remove the second electron from the monovalent cation is called second ionisation enthalpy ( $IE_2$ ). Similarly, we have third, fourth ......... ionisation enthalpies. The values of ionisation energy depends on a number of factors such as (i) size of the atom (ii) screening effect (iii) nuclear charge (iv) half filled and fully filled orbitals (v) shape of orbital.

In a group, the ionisation energy decreases from top to bottom. In a period, the value of ionisation energy increases from left to right with breaks where atoms have somewhat stable configurations.

- 1. Compared to the second ionisation energy ( $IE_2$ ) of an atom, the third ionisation energy  $(IE_3)$  is:
  - (a) the same
- (b) greater
- (c) smaller
- (d) half
- 2. In a period, the ionisation energy is lowest for the:
  - (a) noble gases
- (b) halogens
- (c) alkaline earth metals
- (d) alkali metals
- 3. The electronic configurations of some neutral elements are
  - (A)  $1s^2$ ,  $2s^2$ ; (B)  $1s^2$ ,  $2s^2 2p^1$ ; (C)  $1s^2$ ,  $2s^2 2p^4$ ; (D)  $1s^2$ ,  $2s^2 2p^3$ which of these electronic configurations would be expected to have highest second ionisation energy  $(IE_2)$ ?
  - (a) (A)

(b) (B)

- (c) (C)
- (d) (D)
- The first (IE<sub>1</sub>) and second (IE<sub>2</sub>) ionisation energies (kJmol<sup>-1</sup>) of a few elements are shown below:

	$IE_1$	IE <sub>2</sub>
(A)	2372	5251
(B)	520	7300
(C)	900	1760
(D)	1680	3380
Which	of the above	e elements is likely to be a noble gas?
(a) (A	)	(b) (B)

- (c) (C) (d) (D) 5. In question no. 4, which of the element is likely to be a
  - non-metal?
- (b) (B)

(a) (A) (c) (C)

- (d) (D)
- 6. Which of the order for ionisation energy is correct?
  - (a) Be > B > C > N > O
- (b) B < Be < C < O < N
- (c) B < Be < C < N < O
- (d) B < Be < N < C < O
- 7. Which of the elements Na, Mg, Si and P would have the greatest difference between the first and second ionisation enthalpies?
  - (a) Na

(b) Mg

(c) Si

- (d) P
- 8. The first ionisation energy of Mg, Al, P and S follows the
  - (a) Mg < Al < P < S
- (b) Al < Mg < P < S
- (c) Al < Mg < S < P
- (d) Mg < Al < S < P

## THOUGHT 3

The amount of energy released when an electron is added to an isolated gaseous atom to produce a monovalent anion is called electron affinity or first electron affinity or electron gain enthalpy. The first electron affinity is given a negative sign as the addition of an electron to a neutral atom is an exoergic process. The addition of electron to A requires energy to overcome the force of repulsion. Thus, the second electron affinity is an endoergic process. The magnitude of electron affinity depends on a number of factors such as (i) atomic size (ii) effective nuclear charge (iii) screening effects (iv) half and fully filled orbitals and (v) shape of orbital.

In general, electron affinity increases as the atomic radii decrease in a period. However, there are exceptions when the atoms have stable configurations. In a group, electron affinity decreases as the size increases. However, the members of 3rd period have somewhat higher values than the members in the 2nd period of the same subgroups.

1. What is the  $\Delta H$  of the following reaction?

$$Mg(g) + 2F(g) \longrightarrow Mg^{2+}(g) + 2F^{-}(g)$$
 or  $MgF_2(g)$   
If electron affinity of  $F(g) = -328 \text{ kJ mol}^{-1}$  and  
First ionisation energy of  $Mg = 737.7 \text{ kJ mol}^{-1}$  and  
Second ionisation energy of  $Mg = 1451 \text{ kJ mol}^{-1}$ .

- (a)  $1532.7 \text{ kJ mol}^{-1}$
- (b) 1860.7 kJ mol<sup>-1</sup>
- (c) 2516.7 kJ mol<sup>-1</sup>
- (d) 2844.7 kJ mol<sup>-1</sup>

[Hint: Mg(g) 
$$\longrightarrow$$
 Mg<sup>2+</sup>(g) + 2e  $IE_1 + IE_2 = 2188.7 \text{ kJ mol}^{-1}$   
 $2F(g) + 2e \longrightarrow 2F^ E_A = -2 \times 328 = -656 \text{ kJ mol}^{-1}$   
 $\Delta H = 1532.7 \text{ kJ mol}^{-1}$ 

- 2. Which one of the following arrangements represents the correct order of electron gain enthalpy (with negative sign) of the given atomic species? [C.B.S.E. (P.M.T.) 2005]
  - (a) F < Cl < O < S
- (b) S < O < Cl < F
- (c) O < S < F < CI
- (d) Cl < F < S < O
- 3. Which of the following has least electron affinity?
  - (a) Oxygen
- (b) Argon
- (c) Nitrogen
- (d) Boron
- 4. The electron affinities of halogens are:

$$F = -332$$
,  $Cl = -349$ ,  $Br = -324$ ,  $I = -295$  kJ  $mol^{-1}$ 

The higher value of Cl as compared to that of F is due to:

- (a) higher atomic radius of F
- (b) smaller electronegativity of F
- (c) weaker electron repulsion in Cl
- (d) more vacant p-subshell in Cl
- 5. Which of the following species has the highest electron affinity?
  - (a) F

(b) O

(c) Na<sup>+</sup>

- (d) O
- 6. Which of the following processes is endoergic in nature?
  - (a)  $O^- + e \longrightarrow O^{2-}$  (b)  $Cl + e \longrightarrow Cl^-$ (c)  $S + e \longrightarrow S^-$  (d)  $F + e \longrightarrow F^-$
  - (c)  $S + e \longrightarrow S^-$
- (d)  $F + e \longrightarrow F^-$

### THOUGHT 4

The first  $(\Delta_i H_1)$  and the second  $(\Delta_i H_2)$  ionisation enthalpies in kJ mol<sup>-1</sup> and the electron gain enthalpy in kJ mol<sup>-1</sup> of a few elements are given below:

Elements	$\Delta_i H_1$	$\Delta_i H_2$	$\Delta_{\rm eg} H$
(A)	520	7300	-60
(B)	419	3051	-48
(C)	1681	3374	-328
(D)	1008	1946	295

(E) 2372 5251 +48 (F) 738 1451 -40

Answer the following questions. Only one alternative is correct.

- 1. Which one of the above elements is least reactive?
  - (a) (C)

(b) (D

(c) (E)

- (d) (F)
- 2. Which one of the above elements is most reactive metal?
  - (a) (A)

(b) (B)

(c) (F)

- (d) (D)
- 3. Which one of the above elements is most reactive non-metal?
  - (a) (C)

(b) (D)

(c) (E)

- (d) (F)
- 4. The metal which can form a stable binary halide of the formula  $MX_2$  (X = halogen):
  - (a) (A)

(b) (B)

(c) (F)

- (d) (D)
- 5. Which one of above elements is least reactive non-metal?
  - (a) (C)

(b) (D)

(c) (E)

- (d) (F)
- 6. The metal which can form predominantly stable covalent halide of the formula MX (X = halogen):
  - (a) (F)

(b) (B)

(c) (D)

- (d) (A)
- [Hint: (1) The element (E) having very high ionisation enthalpy and positive electron gain enthalpy would be a noble gas, i.e., least reactive.
  - (2) The element (B) would be most reactive metal as it has low ionisation enthalpy and low negative electron gain enthalpy. Probably it is an alkali metal.
  - (3) The element (C) would be most reactive non-metal as it has high negative value of electron gain enthalpy. Probably it is a halogen.
  - (4) The element (F) would form stable  $MX_2$  as it has first two ionisation enthalpies low and low value of electron gain enthalpy, *i.e.*, it belongs to second group.

- (5) The element (D) would be least reactive non-metal.
- (6) The element (A) has low first ionisation enthalpy but very high second ionisation enthalpy. It would be least reactive alkali metal, *i.e.*, lithium which forms covalent MX.]

### **THOUGHT 5**

Atoms of metals have only a few electrons in their valence shells while atoms of non-metals generally have more electrons in their valence shells. Metallic character is closely related to atomic radius and ionisation enthalpy. Metallic character increases from top to bottom in a group and decreases from left to right in a period. Metallic character is inversely related to electronegativity.

**1.** Which of the following groups contains metals, non-metals and metalloids?

(a) Group 1

(b) Group 17

(c) Group 14

- (d) Group 2
- 2. Non-metals belong to:

(a) s-block elements

(b) p-block elements

(c) d-block elements

- (d) f-block elements
- 3. Considering the elements B, C, N, F and Si, the correct order of their non-metallic character is:

(a) B > C > Si > N > F

- (b) Si > C > B > N > F
- (c) F > N > C > B > Si
- (d)  $F > N > C > S_i > B$
- 4. The electronegativities of the following elements increase in the order:
  - (a) C, N, Si, P

(b) N, Si, C, P

(c) Si, P, C, N

- (d) P. Si. N. C
- 5. Considering the elements B, Al, Mg and K, the correct order of their metallic character is :
  - (a) B > Al > Mg > K
- (b) Al > K > B > Mg
- (c) Mg > Al > K > B
- (d) K > Mg > Al > B
- 6. The element with maximum electronegativity belongs to:
  - (a) period 2, group 17
- (b) period 1, group 18
- (c) period 3, group 17
- (d) period 2, group 16

## INTEGER ANSWER Type Questions

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

- Among the following, the number of elements showing only one non-zero oxidation state is:
   O, Cl, F, N, P, Sn, Tl, Na, Ti
   [I.I.T. 2010]
- **2.** How many groups are occupied by *p*-block elements in long form of periodic table?
- 3. How many diagonal relationships are present in Mendeleev's periodic table?
- **4.** If for an element (X), the values of successive ionisation energies  $I_1$ ,  $I_2$ ,  $I_3$ ,  $I_4$  and  $I_5$  are 800, 2427, 3658, 25024, 32824 kJ mol<sup>-1</sup> respectively, then the number of valence electrons present are :

- 5. How many unpaired electrons are present in Co3+ ion?
- 6. The first ionisation energy of lithium is 5.41 eV and electron gain enthalpy of chlorine is -3.61 eV. The  $\Delta H$  in kJmol<sup>-1</sup> for the reaction :

 $Li(g) + Cl(g) \longrightarrow Li^{+}(g) + Cl^{-}(g)$  is  $1.737 \times 10^{x}$  kJ mol<sup>-1</sup> What is the value of x?

- 7. In a period, the element with largest atomic volume belongs to which of the groups?
- 8. The ionistion energy of lithium is 500 kJ mol<sup>-1</sup>. The amount of energy required to convert 70 mg of lithium atoms in gaseous state into Li<sup>+</sup> ions is:

## Answers

- 1. (2) Na exhibits +1 and F exhibits only -1 oxidation state.
- 2. (6) 13, 14, 15, 16, 17 and 18th groups are occupied by *p*-block elements.
- 3. (3) Li Be B Si Mg Al Si (ii) (iii)
- 4. (3) As the difference between  $I_3$  and  $I_4$  is maximum, so the element (X) has three valence electrons as after losing three electrons, it acquires stable inert gas configuration.
- (4) Co<sup>3+</sup>—24 electrons are present. There are four unpaired electrons.

- 6. (2)  $\Delta H = \text{I.P. of Li} + \text{Eg of Cl} = 5.41 3.61 = 1.8 \text{ eV}$   $\Delta H \text{ mol}^{-1} = 1.8 \times 6.023 \times 10^{23} \text{ eV}$   $= 1.8 \times 6.023 \times 10^{23} \times 1.602 \times 10^{-19} \times 10^{-3} \text{ kJ}$   $= 1.737 \times 10^{2} \text{ kJ}$
- (1) In a period, alkali metal which belongs to group I shows largest atomic volume.
- 8. (5)  $70 \text{ mg} = 70 \times 10^{-3} \text{ g} = \frac{70 \times 10^{-3}}{7} = 1 \times 10^{-2} \text{ mole}$ Amount of energy required =  $1 \times 10^{-2} \times 500 \text{ kJ} = 5 \text{ kJ}$

# 2 INTRODUCTION

From the small number of elements there are derived millions of known compounds, and there are an infinite number possible. This is because there are so many possible ways in which atoms combine to form molecules. This process seems similar to form words of a language from a small number of letters of alphabet. In the formation of words, there are rules of the language which govern the types of possible combination. In the case of atoms, the rules are based on the number and types of electrons which the atoms possess.

Most of the substances are found in nature in the form of clusters or aggregates of atoms. Any such aggregation, in which atoms are held together and which is electrically neutral is called a molecule. The molecules are made of two or more atoms joined together by some force acting between them. The force is termed as a chemical bond. Thus, a chemical bond is defined as a force that acts between two or more atoms to hold them together as a stable molecule or as a force that holds group of two or more atoms together and makes them function as a unit. For example, in water the fundamental unit is the H—O—H molecule, which is described as being held together by the two O—H bonds.

Linus Pauling (1901-1994) won the Nobel Prize in Chemistry in 1954 for his work in chemical bonding

The beginning of our modern theory of bonding can be treated to the concept of valency introduced in 1850. The term valency has been derived from the Latin word 'valentia' which means capacity. Each element was said to have a valency equal to its combining capacity. The number of hydrogen or chlorine atoms with which another atom combines is called its combining capacity. The valency of these two elements was set as, one. Therefore, oxygen which reacts with hydrogen to form H<sub>2</sub>O, was said to have a valency of two. Mg combines with chlorine to form MgCl2, Mg was said to have a valency of two. By using this definition, it is found that elements may have multiple valencies and fractional valencies in certain compounds. For example, nitrogen forms a number of compounds with hydrogen such as NH<sub>3</sub>, N<sub>2</sub>H<sub>4</sub>, N<sub>3</sub>H in which valencies of nitrogen come to 3, 2 and 1/3 respectively.

Thus, the concept of valency as a mere number was very confusing. Later on, the definition of valency was changed. Valency was termed as the number of chemical bonds formed by an atom in a molecule.

The modern concept of valency deals with the interactions between atoms in light of the structure of atoms, *i.e.*, electronic configurations of atoms. The modern concept believes that **electrons are responsible for chemical combination.** It provides tools to find out the answers to the following questions:

- (i) Why do atoms combine?
- (ii) How do atoms combine together?
- (iii) How can the properties of compounds be understood in terms of chemical bonds?

# 2.2 CAUSE OF CHEMICAL COMBINATION

The atoms interact with each other on account of the following reasons:

(i) Decrease in energy: It is a fundamental truth that all natural systems tend to lose potential energy and become more stable. Other things being equal, a system that has stored potential energy is less stable than a system that has none. It is an observed fact that a bonded state is more stable than unbonded state. This is due to the fact that the bonded state has lower potential energy than unbonded state. Hence, when two atoms approach each other, they combine only under the condition that there is a decrease in potential energy.

When two atoms approach each other, new forces of attraction and repulsion come into play. These forces are:

(a) Electrons and nuclei attract one another. Attractive forces are energetically favourable, so an electron attracted to a nucleus is of lower energy and therefore more stable than a free electron.

- (b) Electrons repel each other, raising the energy and reducing the stability.
  - (c) Nuclei repel each other, so reducing the stability also.

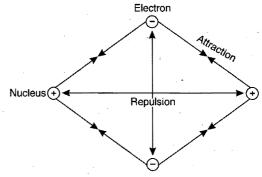

Fig. 2.1 Electrostatic forces in hydrogen molecule

If the net result is attraction, the total potential energy of the system decreases and a chemical bond results. No chemical bonding is possible if net result is repulsion.

(ii) Lewis octet rule: The noble gases are known for their lack of chemical activity. There are no known compounds of helium, neon and argon. Why are these elements so unreactive towards other elements? All these elements have electronic structures that consist of filled cutermost shells. Except for helium, whose electronic configuration is  $1s^2$ , the s-and p-subshells of the highest energy level contain a total of eight electrons. It is, therefore, concluded that  $s^2p^6$  configuration in the outer energy level constitutes a structure of maximum stability and therefore, of minimum energy.

The atoms of all elements when enter into chemical combination try to attain noble gas configuration, *i.e.*, they try to attain either 2 electrons (when only one energy shell) or 8 electrons in their outermost energy level which is of **maximum stability** and hence of **minimum energy**. The tendency of atoms to achieve eight electrons in their outermost shell is known as **Lewis octet rule**. Octet rule was the basis of electronic theory of valency.

Noble gas	Atomic number	Electronic configuration	Configuration of outer energy level
He	2	$1s^2$	$1s^2$
Ne	10	$1s^2$ , $2s^2$ $2p^6$	$2s^2 2p^6$
Ar	18	$1s^2$ , $2s^2 2p^6$ , $3s^2 3p^6$	$3s^2 3p^6$
Kr	36	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$	$4s^2 4p^6$
Xe	54	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ , $5s^2$ $5p^6$	$5s^2 5p^6$
·· Rn	86	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ $4f^{14}$ , $5s^2$ $5p^6$ $5d^{10}$ , $6s^2$ $6p^6$	$6s^2 6p^6$

## 2.3 LEWIS SYMBOLS OF ELEMENTS

Chemical bonding mainly depends on the number of electrons present in the outermost energy level. These electrons are termed as valency electrons. The electronic configuration of sodium (Na) is 2, 8, 1 and that of sulphur has (S) 2, 8, 6. Thus, sodium has one valency electron while sulphur has six valency electrons. In the case of representative elements, the group number (Modern Mendeleev's periodic table) is equal to the number of valency electrons.

The valency electrons in atoms are shown in terms of Lewis symbols. To write Lewis symbol for an element, we write down its symbol surrounded by a number of dots or crosses equal to the number of valency electrons. Paired and unpaired valency electrons are also indicated. The Lewis symbols for hydrogen, sodium, nitrogen, oxygen and chlorine may be written as:

Generalised, Lewis symbols for the representative elements are given in the following table:

#### 2.4 ELECTRONIC THEORY OF VALENCY

The electronic theory of valency owes its rise to the recognition of the existence of electrons in an atom. It was suggested that electrons themselves are responsible for chemical combination. Kossel and Lewis formulated a comprehensive statement which was completed by Langmuir and called electronic theory of valency. The main points of the theory are:

- (i) Valency of an atom depends mainly on the number of electrons present in the outermost orbit. These electrons are termed as valency electrons.
- (ii) Electronic configuration of noble gases is stable, *i.e.*, eight electrons are present in the outermost orbit (except helium having 2 electrons). These gases are chemically inert and do not form any compound.

- (iii) Atoms having less than 8 electrons in the outermost orbit are chemically active. It is the tendency of these atoms to achieve 8 electrons in the outermost orbit. [Hydrogen, lithium, beryllium try to achieve helium configuration.] The number of electrons which take part determines the valency of the atom.
- (iv) There are two ways by which the atoms can acquire noble gas configuration or 8 electrons in the outermost energy level.
  - (a) By losing or accepting electrons.
  - (b) By sharing electrons.

Sharing may be of two types:

- 1. Equal contribution of electrons is made by two atoms and these electrons are then shared equally to form covalent bond, or
- 2. Contribution of an electron pair is made by one atom and both the electrons are shared equally by the two atoms to form coordinate bond. The theory may be summarised in the following way. "The union of two or more atoms involving redistribution of electrons in their outer shells (either by transference or sharing) in such a way so that all the atoms acquire the stable noble gas configuration of minimum energy is known as electronic theory of valency."

Corresponding to the above three ways, there are three types of bonds or linkages which hold the atoms together in a molecule.

- (i) Electrovalent or Ionic bond
- (ii) Covalent bond
- (iii) Coordinate bond

# 2.5 ELECTROVALENT OR IONIC BOND

The chemical bond formed between two or more atoms as a result of the transfer of one or more electrons from electropositive to electronegative atom is called **electrovalent bond**. This bond is also called **ionic** or **polar bond**.

The electron transfer results in the formation of cations and anions. The cations are positively charged ions whereas anions are negatively charged ions. Oppositely charged ions are attracted to each other and a bond between them is formed. The bond existing between the oppositely charged ions is called an ionic or electrovalent or polar bond or the bond formed by the electrostatic attraction between positive and negative ions is called an ionic bond. Compounds containing ionic bonds are called ionic, electrovalent or polar compounds.

[Note: Electrovalent bond is not possible between similar atoms. This type of bonding requires two atoms of different nature, one atom should have the tendency to lose electron or electrons, *i.e.*, electropositive in nature and the other atom should have the tendency to accept electron or electrons, *i.e.*, electronegative in nature. Actually ionic bond is not a true bond but just electrostatic attraction between closely packed ions. It is non-directional in nature.]

# Examples of Electrovalent Bond

(i) Potassium chloride: The free potassium atom has one valency electron (electronic configuration 2, 8, 8, 1), *i.e.*,  $4s^1$  whereas, the chlorine atom has seven valency electrons (electronic configuration 2, 8, 7), *i.e.*,  $3s^2$   $3p^5$ . In forming an ionic bond, the potassium atom loses its valency electron which is accepted by chlorine atom. As a result potassium achieves noble gas configuration of argon (2, 8, 8) and becomes a positive ion (K<sup>+</sup>). Chlorine achieves noble gas configuration of argon (2, 8, 8) and acquires a negative charge (Cl<sup>-</sup>). The attraction between potassium ion and chloride ion is an ionic bond.

A shorthand way of showing the formation of potassium chloride from potassium and chlorine atoms involves electron dot symbols.

$$K^{\times}$$
  $Cl: = K^{+}$   $[\times Cl:]$  or  $K^{+}Cl^{-}$  (2, 8, 8, 1) (2, 8, 7) (2, 8, 8) (2, 8, 8)

(ii) Sodium sulphide: Sodium combines with sulphur to form sodium sulphide, Na<sub>2</sub>S. Two sodium atoms, each loses its valency electron, are converted into sodium ions with neon like configuration (2, 8). Sulphur (2, 8, 6) which has six electrons in the valency shell gains two electrons to achieve the argon like configuration (2, 8, 8).

(iii) Magnesium fluoride: Magnesium combines with fluorine to form  $MgF_2$ . Magnesium atom loses two electrons and is converted into magnesium ion  $(Mg^{++})$  with neon like configuration (2, 8).

Each fluorine atom having seven electrons in valency shell requires one electron to acquire neon configuration (2, 8).

In all ionic compounds, the electrons lost by one or more atoms in achieving the noble gas configuration of a cation are accepted by the requisite number of companion atoms to achieve noble gas configuration of the anions. Thus,

(number of cations formed)  $\times$  (number of electrons lost in forming one cation) = (number of anions formed)  $\times$  (number of electrons gained in forming one anion).

# Conditions for Forming Electrovalent or Ionic Bond

The following conditions favour the formation of an electrovalent bond.

- (i) Number of valency electrons: One atom should possess 1, 2 or 3 valency electrons while the other atom should have 5, 6 or 7 valency electrons. The atom which changes into cation should possess 1, 2 or 3 valency electrons, *i.e.*, it should belong to group IA, IIA or IIIA. It should be metallic or electropositive in nature. The other atom which changes into anion should possess 5, 6 or 7 electrons in the valency shell, *i.e.*, it should belong to group VA, VIA or VIIA. It should be non-metallic or electronegative in nature. The atoms of transition metals can also lose electron or electrons and converted into cations. Thus, they can also form electrovalent bonds but do not acquire inert gas configuration always.
- (ii) Difference in electronegativity: The formation of an electrovalent bond will be easier if the difference in the electronegativities of the two atoms is high. A difference of about 2 is necessary for the formation of an electrovalent bond. The electronegativity of sodium is 0.9 and that of fluorine is 4.0. Since the difference is 3.1 both will readily form an electrovalent bond.
- (iii) Overall decrease in energy: In the formation of an electrovalent bond, there must be overall decrease in energy, *i.e.*, energy must be released. Energy changes are involved in the following steps:
- (a) Energy equivalent to ionisation energy is required to convert a neutral isolated gaseous atom into a cation.

$$A + \text{ionisation energy} = A^+ + e^- \qquad \dots \text{(i)}$$

Lower the value of ionisation energy of an atom, greater will be the ease of formation of the cation from it, *i.e.*, one atom should have low value of ionisation energy.

(b) Energy equivalent to **electron affinity** is released when an electron is added to a neutral isolated gaseous atom to make it univalent anion.

$$B + e^{-} = B^{-} +$$
electron affinity ...(ii)

Higher the value of electron affinity of the atom, greater the ease of formation of the anion from it, *i.e.*, other atom should have high value of electron affinity.

(c) Lattice energy: Cation and anion attract each other by electrostatic force of attraction to give a molecule  $A^+B^-$ .

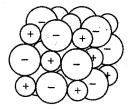

Fig. 2.2 Crystals of ionic compounds

Since the electrostatic field of a charged particle extends in all directions, a positive ion is surrounded by a number of negatively charged ions while each negative ion similarly surrounded by a number of positive ions. These cations and anions arrange systematically in an alternating cation-anion pattern as shown in Fig. 2.2. This is called a crystal lattice. This process of clustering ions increases the force of attraction and thus potential energy decreases. The energy released when the requisite number of positive and negative ions are condensed into crystal to form one mole of the compound is called lattice energy (III step). Higher the lattice energy, greater will be the ease of forming an ionic compound. If the energy released in steps (II) and (III) is greater than the energy used in step (I), the formation of an ionic compound will be favoured.

The value of lattice energy depends on the charges present on the two ions and the distance between them. According to Coulomb's law, the force of attraction (F) between two oppositely charged ions in air with charges equal to  $q_1$  and  $q_2$  and separated by a distance d is given by,

$$F = \frac{1}{4\pi\varepsilon_0 K} \frac{q_1 q_2}{d^2}$$

where d is equal to sum of ionic radii of the two ions and K is dielectric constant of medium.

$$F = \frac{1}{4\pi\varepsilon_0 K} \frac{q_1 q_2}{(r_A^+ + r_B^-)^2}$$

The value of F increases if (i)  $q_1$  and  $q_2$  are high and (ii)  $(r_A^+ + r_B^-)$  is small.

The stability of the ionic compound and the strength of the ionic bond depends on the value of F. Higher the value of F, greater shall be the stability of the ionic compound and hence greater shall be the strength of the ionic bond. For example, NaCl is more stable than CsCl as  $(r_{Na}^+ + r_{Cl}^-)$  is less than  $(r_{Cs}^+ + r_{Cl}^-)$ . MgO is more stable than NaCl as the product  $q_1q_2$  is four times more in MgO than NaCl.

The lattice energy can also be defined as the energy required to separate one mole crystal of an ionic compound into gaseous ions.

$$MX_{(s)} \xrightarrow{+L.E.} M_{(g)}^+ + X_{(g)}^-$$

Theoretically, lattice energy is given by Born-Lande equation.

$$L.E. = \frac{NoMZ^+Z^-e^2}{r} \left[ 1 - \frac{1}{n} \right]$$

where No = Avogadro's number

M = Madelung constant (depends on crystal structure)

 $Z^{+}$  and  $Z^{-}$  = Charges on cation and anion

e = charge on the electron,

 $r = r^+$  (radius of cation) +  $r^-$  (radius of anion)

n = Born constant (depends on the electronic configuration of ions)

Note: In a number of cases, the results obtained from Born-Lande equation are different than experimental values.

Thus, the Born-Lande equation is not perfect and needs modification.

#### Conclusions

- (i) An ionic bond is purely electrostatic in nature.
- (ii) Its formation is favoured by:
- (a) **Low ionisation potential (I.P.)** of the element that forms a cation on losing electron(s). The element should be metal, *i.e.*, electropositive in nature.
- (b) **High electron affinity (E.A.)** of the element that forms an anion on gaining electron(s). The element should be non-metal, *i.e.*, electronegative in nature.

- (c) **High lattice energy (L.E.):** The energy released when isolated ions form a crystal. The value of lattice energy depends on the charges present on the two ions and distance between them. It shall be high if charges are high and ionic radii are small.
- (d) The summation of three energies should be negative, *i.e.*, energy is released.

I.P. + E.A. + L.E. = 
$$-ive$$

- (iii) Highly electropositive elements of groups I and II combine with highly electronegative elements of VI and VII (or 16th and 17th) groups to form electrovalent or ionic compounds. Halides, oxides, sulphides, nitrides and hydrides of alkali and alkaline earth metals are generally ionic.
- (iv) Greater the difference of electronegativity between two atoms, higher will be the possibility of ionic bond formation.
- (v) **Electrovalency**: The capacity of an element to form electrovalent or ionic bond is termed as **electrovalency**. The capacity is measured in terms of the electrons lost or accepted. Thus, electrovalency of an element is equal to the number of electrons lost by an atom of the element or gained by the atom of the element as to acquire inert gas configuration. The elements which lose electron or electrons show positive electrovalency and the elements which gain electron or electrons show negative electrovalency. Generally positive and negative signs are not used in practice and only the number is taken to represent electrovalency.

Element	No: of ele- ctrons lost or gained by an atom	Electro- valency	Change in electronic configuration
Na	1 (lost)	1 (Monovalent)	2, 8, 1 to 2, 8 (Na <sup>+</sup> )
K	1 (lost)	1 (Monovalent)	2, 8, 8, 1 to 2, 8, 8 (K <sup>+</sup> )
Mg	2 (lost)	2 (Divalent)	2, 8, 2 to 2, 8 (Mg <sup>++</sup> )
Ca	2 (lost)	2 (Divalent)	2, 8, 8, 2 to 2, 8, 8 (Ca <sup>++</sup> )
Al	3 (lost)	3 (Trivalent)	2, 8, 3 to 2, 8 (A1 <sup>+++</sup> )
F	1 (gained)	1 (Monovalent)	2, 7 to 2, 8 (F <sup>-</sup> )
Cl	1 (gained)	1 (Monovalent)	2, 8, 7 to 2, 8, 8 (C1 <sup>-</sup> )
О	2 (gained)	2 (Divalent)	2, 6 to 2, 8 (O <sup></sup> )
S	2 (gained)	2 (Divalent)	2, 8, 6 to 2, 8, 8 (S <sup></sup> )
N	3 (gained)	3 (Trivalent)	2, 5 to 2, 8 (N)

# 2.6 DETERMINATION OF LATTICE ENERGY

The lattice energy of an ionic solid is determined experimentally by a process known as **Born-Haber cycle**. This cycle is based on Hess's law, *i.e.*, the formation of an ionic crystal may occur either by direct combination of the elements or by an alternate process in which the following steps are involved. In both cases energy involved is the same.

- (i) The reactants are converted into gaseous state.
- (ii) The gaseous atoms are converted into ions.
- (iii) The gaseous ions are combined to form ionic compound.

For example, the formation of *KF* can occur either directly or in steps.

## **Direct Combination**

$$K(s) + \frac{1}{2}F_2(g) \longrightarrow KF(s)$$

 $\Delta H$  or heat of formation = -562.6 kJ mol<sup>-1</sup>

## In Steps:

(i) Conversion of solid potassium into gaseous state.

$$K(s) \longrightarrow K(g)$$

H.A. or heat of atomisation =  $+89.6 \text{ kJ mol}^{-1}$ 

(ii) Formation of a cation.

$$K(g) \longrightarrow K^+(g) + e^-$$

I.P. or first ionisation potential =  $+419.0 \text{ kJ mol}^{-1}$ 

(iii) Conversion of molecular fluorine into gaseous atomic fluorine.

$$\frac{1}{2}F_2(g) \longrightarrow F(g)$$

1/2 H.D. or 1/2 (heat of dissociation) = + 1/2 (158.2) = 79.1 kJ mol<sup>-1</sup>

(iv) Formation of anion.

$$F(g) + e^{-} \longrightarrow F^{-}(g)$$

E.A. or first electron affinity =-332.6 kJ mol<sup>-1</sup>

(v) Combination of  $K^+(g)$  and  $F^-(g)$  to form KF(s).

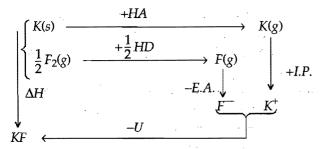

$$K^+(g) + F^-(g) \longrightarrow KF(s)$$

L.E. or lattice energy = -U kJ mol<sup>-1</sup>

On the basis of Hess's law

$$-562.6 = 89.6 + 419.0 + 79.1 - 332.6 - U$$
  
 $U = 817.7 \text{ kJ mol}^{-1}$ ,  
*i.e.*, lattice energy of  $KF = -817.7 \text{ kJ mol}^{-1}$ 

Born-Haber cycle for formation of *KF*(*s*) may be represented as:

Lattice energies of some ionic compounds:

Name of the compound	Lattice energy in kJ mol <sup>-1</sup>	Name of the compound	Lattice energy in kJ mol <sup>-1</sup>
NaCl	769	NaBr	732
KCl	701	CaBr <sub>2</sub>	2132
MgCl <sub>2</sub>	2326	LiI	730
BaCl <sub>2</sub>	2033	NaI	682
Na <sub>2</sub> O	2481	MgI <sub>2</sub>	1944
MgO	37.95	BaI <sub>2</sub>	1831
CaO	3414	CaF <sub>2</sub>	2630
BaO	3029	AlCl <sub>3</sub>	5492

From the above table, it is clear that lattice energy is affected by both the charge and size of the ions. Compounds with higher charges have large lattice energies and lattice energy decreases as the size of one or both the ions, *i.e.*, cation and anion, increases. In general, the compounds having high values of lattice energy possess the following characteristics:

- (i) High stability
- (ii) High melting points
- (iii) Low solubility in water (If lattice energy is higher than hydration energy).

# 2.7 TYPES OF IONS

The following types of ions are encountered.

- (i) Ions with inert gas configuration: The atoms of the representative elements of group I, II and III by complete loss of their valency electrons and the elements of group V, VI and VII by gaining 3, 2 and 1 electrons respectively form ions either with  $ns^2$  configuration or  $ns^2p^6$  configuration.
- (a) Ions with  $1s^2$  (He) configuration:  $H^-$ ,  $Li^+$ ,  $Be^{2+}$ , etc. The formation of  $Li^+$  and  $Be^{2+}$  is difficult due to their small size and high ionisation energy.
- (b) Ions with  $ns^2p^6$  configuration: More than three electrons are hardly lost or gained in the ion formation.

Cations :  $Na^+$ ,  $Ca^{2+}$ ,  $Al^{3+}$ , etc. Anions :  $Cl^-$ ,  $O^{2-}$ ,  $N^{3-}$ , etc. (ii) Ions with pseudo inert gas configuration: The  $\rm Zn^{2+}$  ion is formed when zinc atom loses its outer 4s electrons. The outer shell configuration of  $\rm Zn^{2+}$  ion is  $3s^23p^63d^{10}$ . The  $ns^2np^6nd^{10}$  outer shell configuration is often called pseudonoble gas configuration which is considered as stable one.

(iii) Exceptional configuration: Many d- and f- block elements produce ions with configurations different than the above two. Ions like Fe<sup>3+</sup>, Mn<sup>2+</sup>, etc., attain a stable configuration half filled d-orbitals.

Fe<sup>3+</sup> 
$$3s^2 3p^6 3d^5$$
;  $Mn^{2+} 3s^2 3p^6 3d^5$ 

Examples of other configurations are many.

Ti<sup>2+</sup> 
$$(3s^2 3p^6 3d^2)$$
; V<sup>2+</sup>  $(3s^2 3p^6 3d^3)$   
Cr<sup>2+</sup>  $(3s^2 3p^6 3d^4)$ ; Fe<sup>2+</sup>  $(3s^2 3p^6 3d^6)$ 

However, such ions are comparatively less stable.

- (iv) Ions with  $ns^2$  configuration: Heavier members of groups III, IV and V lose p-electrons only to form ions with  $ns^2$  configuration.  $TI^+$ ,  $Sn^{2+}$ ,  $Pb^{2+}$ ,  $Bi^{3+}$  are the examples of this type. These are stable ions.
- (v) Polyatomic ions: The ions which are composed of more than one atom are called polyatomic ions. These ions move as such in chemical reactions. Some common polyatomic ions are:

$$\mathrm{NH}_{4}^{+}(\mathrm{Ammonium});$$
  $\mathrm{NO}_{3}^{-}(\mathrm{Nitrate});$   $\mathrm{PO}_{4}^{3-}(\mathrm{Phosphate});$   $\mathrm{SO}_{4}^{2-}(\mathrm{Sulphate});$   $\mathrm{SO}_{3}^{2-}(\mathrm{Carbonate});$   $\mathrm{SO}_{3}^{2-}(\mathrm{Sulphite}),$  etc.

The atoms within the polyatomic ions are held to each other by covalent bonds.

The electrovalencies of an ion (any type) is equal to the number of charges present on it.

# 2.8 METHOD OF WRITING FORMULA OF AN IONIC COMPOUND

In order to write the formula of an ionic compound which is made up of two ions (simple or polyatomic) having electrovalencies x and y respectively, the following points are followed:

- (i) Write the symbol of the ions side by side in such a way that positive ion is at the left and negative ion at the right as *AB*.
- (ii) Write their electrovalencies in figures on the top of each symbol as  $A^xB^y$ .
- (iii) Divide their valencies by H.C.F.
- (iv) Now apply criss cross rule as  $A \bowtie B$ , *i.e.*, formula  $A_yB_x$ .

#### Examples:

Calcium chloride $ \begin{array}{cccccccccccccccccccccccccccccccccc$	- Total Prob	and the second of the second o
Potassium phosphate $ \begin{array}{ccccccccccccccccccccccccccccccccccc$	Calcium chloride	$\begin{array}{c} 2 \\ Ca \end{array} \begin{array}{c} 1 \\ C1 = CaCl_2; \end{array}$
Magnesium nitride $\begin{array}{cccccccccccccccccccccccccccccccccccc$	Aluminium oxide	$\begin{array}{c} 3 \\ \text{Al} & O = \text{Al}_2\text{O}_3; \end{array}$
Magnesium nitride $ \begin{array}{cccccccccccccccccccccccccccccccccc$	Potassium phosphate	$ \begin{array}{c} 1 \\ K \end{array} $ $ \begin{array}{c} 3 \\ PO_4 = K_3 PO_4; \end{array} $
Calcium oxide CaO or $Ca \sim 1$ $Ca \sim 0 = CaO;$ $Ca \sim 2$	Magnesium nitride	0 0
Ammonium sulphate $1 \times 2$ $NH_4 \times SO_4 = (NH_4)_2SO_4$	2 2 Calcium oxide CaO or	$1 \setminus 1$
1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1	Ammonium sulphate	$\frac{1}{NH_4}$ $\frac{2}{SO_4} = (NH_4)_2 SO_4$

The following table summarises general formulae of the binary ionic compounds formed by representative elements:

Metal	Non-metal	General formula	Ions present	Example
IA	VIIA	MX	M <sup>+</sup> X <sup>-</sup>	NaCl
IIA	VIIA	$MX_2$	$M^{2+}2X^{-}$	CaCl <sub>2</sub>
IIIA	VIIA	$MX_3$	$M^{3+}3X^{-}$	AlF <sub>3</sub>
IA	VIA	$M_2X$	$2M^{+}X^{2-}$	$K_2S$
IIA	VIA	MX	$M^{2+}X^{2-}$	CaO
IIIA	VIA	$M_2X_3$	$2M^{3+}3X^{2-}$	$Al_2O_3$
IA	VA ·	$M_3X$	3M <sup>+</sup> X <sup>3</sup>	Na <sub>3</sub> P
IIA	VA	$M_3X_2$	$3M^{2+}2X^{3-}$	$Mg_3N_2$
IIIA	VA	MX	$M^{3+}X^{3-}$	AlP

# 2.9 DIFFERENCE BETWEEN ATOMS AND IONS

The following are the points of difference between atoms and ions:

	Atoms	Ions	
1.	Atoms are perfectly neutral in nature, i.e., number of protons equal to number of electrons.  Na (protons 11, electrons 11)	Ions are charged particles, cations are positively charged, <i>i.e.</i> , number of protons more than the number of electrons. Anions are negatively charged, <i>i.e.</i> , number of protons less than the number of electrons.  Na <sup>+</sup> (protons 11, electrons 10) CI <sup>-</sup> (protons 17, electrons 18)	
2.	Except noble gases, atoms have less than 8 electrons in the outermost orbit,	Ions have generally 8 electrons in the outermost orbit, <i>i.e.</i> , $ns^2np^6$ configuration.	
	Na 2, 8, 1; Ca 2, 8, 8, 2 Cl 2, 8, 7; S 2, 8, 6	Na <sup>+</sup> 2, 8; Cl <sup>-</sup> 2, 8, 8 Ca <sup>2+</sup> 2, 8, 8	
3.	Chemical activity is due to loss or gain or sharing of electrons as to acquire noble gas configuration.	The chemical activity is due to the charge on the ion. Oppositely charged ions are held together by electrostatic forces.	

Note: There is a difference in their relative sizes. A positive ion is always smaller and a negative ion is always larger than the corresponding atom.

Na 1.54 Å , *i.e.*, Na<sup>+</sup> < Na 
$$\begin{array}{c} \text{Cl } 0.99 \text{ Å} \\ \text{Cl}^- 1.81 \text{ Å} \end{array}$$
 , *i.e.*, Cl<sup>-</sup> > Cl

# 2.10 GENERAL CHARACTERISTICS OF ELECTROVALENT COMPOUNDS

The compounds having electrovalent bonds are called electrovalent compounds. The following are some of the general properties shown by these compounds:

(i) Crystalline nature: Electrovalent compounds are usually crystalline in nature. The constituent units in an ionic crystal are ions and not molecules. These ions are arranged together in a regular way in an ionic lattice. Force of attraction between the ions is non-directional and extends in all directions. Thus, electrovalent compounds consist of three dimensional solid aggregates. Normally each ion is surrounded by a number of oppositely charged ions and this number is called the coordination number. The coordination numbers of positive and negative ions are the same if there are equal number of both the ions as in NaCl. The geometry of the ionic crystal depends on radius ratio of the cation and anion  $(r_c + /r_{g^-})$ . In the case of NaCl crystal, the coordination number is six that is each Na<sup>+</sup> ion is surrounded by equally spaced six ClT ions placed at the corners of regular octahedron and similarly each Cl ion is surrounded by six equally spaced Na<sup>+</sup> ions placed at the corners of an octahedron (see Fig. 2.3 and 2.4). The shape of NaCl unit cell is cubical.

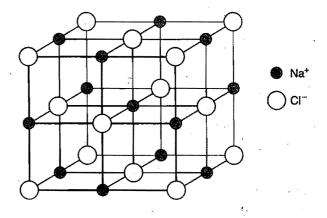

Fig. 2.3 Actual compact structure of sodium chloride crystals

As electrovalent compounds have closed packed structures and ions have no freedom of movement, these are not found in liquid or gaseous states under ordinary conditions of temperature and pressure and exist as solids.

Electrovalent compounds have low volatility and high stability because strong electrostatic forces of attraction bring these ions very close to one another, thereby decreasing the volume of the crystal and hence, these compounds have high density.

(ii) Melting and boiling points: Due to strong electrostatic forces of attraction, the ions are held tightly in their positions in the crystal lattice. To dislodge the ions from their positions, a considerable amount of energy is needed to overcome the forces of attraction. Thus, electrovalent compounds possess high melting and boiling points. Melting point of ionic solid is sharp and fixed. Cooling curve of ionic solids is also not smooth (see cooling curve on Page 76).

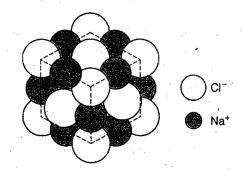

Fig. 2.4 Cubical structure of sodium chloride crystal

(iii) Hard and brittle: Electrovalent compounds are hard in nature. The hardness is due to strong forces of attraction between oppositely charged ions which keep them in their alloted positions. The brittleness of the crystals is due to movement of a layer of a crystal on the other layer by application of external force when like ions come infront of each other. The forces of repulsion come into play. The breaking of crystal occurs on account of these forces or repulsion.

(iv) Solubility: Electrovalent compounds are fairly soluble in polar solvents and insoluble in non-polar solvents. The polar solvents have high values of **dielectric constants.\*** Water, the polar solvent, is one of the best solvents as it has a high value of dielectric constant. Due to high value of dielectric constant, the electrostatic force of attraction between the ions decreases and these ions get separated and ultimately solvated by the molecules of the solvent. The non-polar solvents have very low value of dielectric constants\* and are not capable of dissolving electrovalent compounds.

The values of dielectric constants of some of the compounds are given below:

Compound Water Methyl Alc. Ethyl Alc. Acetone Ether Dielectric constant 81 35 27 21 4.1

Capacity to dissolve electrovalent compounds decreases

The solubility in polar solvents like water can also be explained by saying that the molecule of water is a dipole.

The positive end of the dipole interacts with the negative ion of the electrovalent compound and the negative end of the dipole interacts with the positive ion of the same electrovalent compound as shown in Fig. 2.5. Water molecules pull

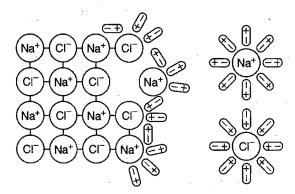

Fig. 2.5 Solvation of NaCl in water

the ions from the crystal lattice. These ions are then surrounded by water dipoles with the oppositely charged ends directed towards them. These solvated ions lead an independent existence and are thus dissolved in water.

The solubility of an electrovalent compound in a polar solvent can also be explained on the basis of lattice and solvation (hydration in case if water is solvent) energies. The electrovalent compound dissolves in a solvent if the value of solvation energy is higher than the lattice energy of the electrovalent compound. When the compound is dissolved in a solvent, first the compound is broken down into ions. The energy required for this process is called lattice energy.

$$AB$$
 + Lattice energy =  $A^+$  +  $B^-$ 

These ions are surrounded by solvent molecules. This process is called solvation. This process is exothermic.

$$A^+ + x(\text{solv.}) \longrightarrow [A (\text{solv.})_x]^+ + \text{energy}$$
  
 $B^- + y(\text{solv.}) \longrightarrow [B (\text{solv.})_y]^- + \text{energy}$ 

The value of solvation energy depends on the relative size of the ions. Smaller the ion more of solvation, hence solvation energy will be high. The non-polar solvents do not form solvated ions and thus no energy is released. Hence, solubility of electrovalent compounds in non-polar solvents is not possible. It is notable point that if an electrovalent compound dissolves in non-polar solvent then colloidal solution is formed, *e.g.*, NaCl form colloidal solution in kerosene.

(v) Electrical conductivity: Electrovalent solids do not conduct electricity. The reason is that the ions, on account of electrostatic forces of attraction, remain intact occupying fixed positions in the crystal lattice. The ions, thus, do not move where electric current is applied.

<sup>\*</sup>The dielectric constant of a solvent is defined as its capacity to weaken the force of attraction between the electrical charges immersed in that solvent.

When electrovalent compounds are melted or dissolved in a polar solvent, the ions become mobile. They are attracted towards the respective electrodes and act as carrier of electric current. Thus, electrovalent compounds in the molten state or in solution conduct electricity.

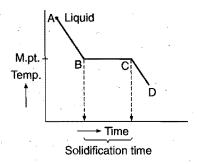

- (vi) Space isomerism: The electrovalent bond is nonrigid and non-directional. Thus, the electrovalent compounds do not show space isomerism or stereo-isomerism.
- (vii) Isomorphism: Compounds having same electronic structures are isomorphous to each other. For example, sodium fluoride and magnesium oxide are isomorphous to each other.

Potassium sulphide, potassium chloride and calcium chloride are isomorphous to each other.

(viii) Ionic reactions: Electrovalent compounds furnish ions in solution. The chemical reactions are due to the presence of these ions. Such reactions are fast. For example, SO<sub>4</sub><sup>2</sup>-ions present in Na<sub>2</sub>SO<sub>4</sub> solution, form white precipitate of BaSO<sub>4</sub> as soon as BaCl<sub>2</sub> solution is added to it.

$$Na_2SO_4 \longrightarrow 2Na^+ + SO_4^2$$
 $BaCl_2 \longrightarrow Ba^{2+} + 2Cl^ Ba^{2+} + SO_4^{2-} \longrightarrow BaSO_4 \downarrow$ 
White precipitate

(ix) Cooling curve: Cooling curve of an ionic compound is not smooth, it has two break points corresponding to time of solidification.

# 2.11 VARIABLE ELECTROVALENCY

Certain elements (metals) show more than one electrovalency in their electrovalent compounds. The atoms of these elements lose different number of electrons under different conditions, thereby showing variable electrovalency. The following are two reasons for variable electrovalency:

(i) Instability of the core: The residue configuration left after the loss of valency electrons (electrons present in the outermost energy level) is called a core or kernel. In the case of the atoms of transition elements, ions formed after the loss of valency electrons do not possess a stable core as the configuration of outermost shell is not ns<sup>2</sup>np<sup>6</sup> but ns<sup>2</sup>np<sup>6</sup>d <sup>1 to 10</sup>. The outershell generally loses one or more electrons giving rise to metal ions of higher valencies. The variable valencies of iron and copper can be explained on this basis.

Fe 26 2, 8, 8 + 6, 2 
$$3s^2 3p^6 3d^6$$
,  $4s^2$   
Fe<sup>2+</sup> 24 2, 8, 8 + 6  $3s^2 3p^6 3d^6$  (Not stable)  
Fe<sup>3+</sup> 23 2, 8, 8 + 5  $3s^2 3p^6 3d^5$  (Stable)

Thus, iron shows +2 and +3 valencies. The compounds, in which iron is in trivalent state, i.e., ferric compounds are more stable than the compounds in which iron is in divalent state (ferrous compounds). The atom of copper possesses one electron in the outermost shell. It loses this electron to form Cu<sup>+</sup> (cuprous) ion.

Cu 29 2, 8, 18, 1 
$$3s^2 3p^6 3d^{10}$$
, 4s  
Cu<sup>+</sup> 28 2, 8, 18  $3s^2 3p^6 3d^{10}$ 

Cu<sup>+</sup> 28 2, 8, 18  $3s^2 3p^6 3d^{10}$ The  $s^2p^6d^{10}$  configuration is not as stable as  $s^2p^6$ configuration and the nuclear charge is not sufficiently strong to hold all the electrons intact in their positions. Thus, Cu<sup>+</sup> ion loses one more electron to form Cu<sup>2+</sup> (cupric) ion. The Cu<sup>2+</sup> ion is quite stable as the nuclear charge is sufficient to hold 27 electrons intact.

Cu<sup>2+</sup> 2, 8, 17 
$$3s^2 3p^6 3d^9$$

Thus, cupric compounds are more stable than cuprous compounds.

The above two explanations fail to account why

- (a) Co<sup>2+</sup> ion cannot be easily converted into Co<sup>3+</sup> ion like Fe<sup>2+</sup> ion.
- (b) Zn2+ ion does not lose one more electron as its configuration  $(3s^2 3p^6 3d^{10})$  is similar to Cu<sup>+</sup> ion.

In general, we can say that whenever the core is unstable, it loses one or more electrons to show higher valency and if the core is comparatively stable it always resists the loss of

The cores of Co<sup>2+</sup> ion and Zn<sup>2+</sup> ion are comparatively stable as the nuclear charges are sufficient to hold all the electrons intact in their positions. Co<sup>2+</sup> ion changes into Co<sup>3+</sup> ion in presence of an oxidising agent, but cobaltous compounds are comparatively more stable than cobaltic compounds.

[Note: Cu2+ is more stable in aqueous solution than Cu+ due to high hydration energy.]

(ii) Inert pair effect: Some of heavier representative elements of third, fourth and fifth groups having configurations of the outermost shell  $ns^2np^1$ ,  $ns^2np^2$  and  $ns^2np^3$ show valencies with a difference of 2, i.e., (1; 3), (2; 4), (3; 5), respectively. In the case of lower valencies, only the electrons present on p-subshell are lost and  $ns^2$  electrons remain intact. The reluctance of s-electron pair to take part in bond formation is known as the **inert pair effect**. A partial explanation of the inert pair effect is due to the fact that outer  $ns^2$  electrons penetrate to some extent to penultimate orbit consisting 18 electrons thereby attracted strongly towards nucleus. Inert pair effect increases in a group as the atomic number increases.

(III group) 2, 8, 18, 32, 18,  $6s^2 6p^1$ Tl  $T1^+$ 2, 8, 18, 32, 18, 6s<sup>2</sup> Only 6p electron is lost (IV group) 2, 8, 18, 18,  $5s^2 5p^2$ Sn Sn<sup>2+</sup>  $2, 8, 18, 18, 5s^2$ Only 5p electrons are lost (IV group) 2, 8, 18, 32, 18,  $6s^2$   $6p^2$ Pb 2, 8, 18, 32, 18,  $6s^2$  Only 6p electrons are lost (V group) 2, 8, 18, 32, 18,  $6s^2 6p^3$ Bi Bi<sup>3+</sup> 2, 8, 18, 32, 18,  $6s^2$  Only 6p electrons are lost

When sufficient energy is available, the s-electrons also enter into bond formation and higher valencies are observed. This tendency to show higher valencies is less in the case of Tl, Pb and Bi but more in the case of comparatively lighter elements such as In, Sn, Sb, etc.

#### **Conclusions**

- 1. In group 13, Ga, In and Tl show variable valencies of +3 and +1. The stability of +3 state decreases while that of +1 state increases. Tl<sup>+</sup> is thus more stable than Tl<sup>3+</sup>.
- 2. In group 14, Ge, Sn and Pb show variable valencies of +4 and +2. The stability of +4 state decreases while that of +2 state increases. Thus, Ge<sup>4</sup> is more stable than Ge<sup>2+</sup> while Pb<sup>2+</sup> is more stable than Pb<sup>4+</sup>.
- 3. In group 15, P, As, Sb and Bi show variable valencies of +5 and +3. The stability of +5 state decreases while that of +3 state increases.

# 2.12 COVALENT BOND

The second mode of combination was first proposed by Lewis, in 1916, that there are atoms which attain noble gas configuration by sharing one or more electron pairs when each atom contributes equally. The pair or pairs of electrons become a common property of both. Such a bond is possible between similar and dissimilar atoms. In this bond the atoms do not acquire any charge as the electron or electrons are not lost completely. The electrons, which are shared, occupy such a position in between the nuclei of the two atoms where there is maximum force of attraction from the two nuclei. The bond is, therefore, termed as non-polar bond.

"A chemical bond formed by sharing one or **more** electron pairs between atoms when each atom contributes equally is called a covalent bond."

Covalent bond may be single, double or a triple bond. Double and triple covalent bonds are called **multiple covalent bonds**. Single covalent bond is formed by sharing of only one electron pair. This bond is represented by single dash (—). Double and triple covalent bonds are formed

when atoms bonded together share two or three electron pairs, respectively. These bonds are represented by double dash (=) and triple dash (=) respectively. Some examples of covalent bonding are given below:

(i) Formation of hydrogen molecule: In the formation of hydrogen molecule, each hydrogen atom contributes one electron and then the pair is shared between two atoms. Both the atoms acquire stable configuration of helium. Thus, the molecule consists of one single covalent bond.

$$H^{\times} + {}^{\bullet}H \longrightarrow H \xrightarrow{\times} H$$
 or  $H \longrightarrow H$ 

(ii) Formation of chlorine molecule: Chlorine atom has seven electrons in the valency shell. In the formation of chlorine molecule, each chlorine atom contributes one electron and then the pair of electrons is shared between two atoms. Both the atoms acquire stable configuration of argon.

(iii) Formation of HCl molecule: Both hydrogen and chlorine contribute one electron each and then the pair of electrons is equally shared. Hydrogen acquires the configuration of helium and chlorine acquires the configuration of argon.

$$H^{\times}$$
 .C1:  $H$  .C1 or  $H$ —C1 (2) (2,8,8)

(iv) Formation of water molecule: Oxygen atom has 6 valency electrons. It can achieve configuration of neon by sharing two electrons, one with each hydrogen atom.

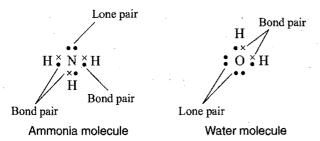

(v) Formation of methane: Carbon has four electrons in the valency shell. It can achieve stable configuration of neon by sharing four electrons with four hydrogen atoms, one with each hydrogen atom. Each hydrogen atom acquires helium configuration.

(vi) Formation of  $O_2$  molecule: Each oxygen atom contributes two electrons and two pairs of electrons are then shared equally. Both the atoms acquire configuration of neon.

(vii) Formation of N<sub>2</sub> molecule: Nitrogen atom has five valency electrons. Both nitrogen atoms achieve configuration of neon by sharing 3 pairs of electrons, *i.e.*, each atom contributes 3 electrons.

$$(2.5) \quad (2.5) \quad (2.8) \quad (2.8) \quad (2.8)$$
 or N\implies N

The shared pairs of electrons present between the atoms are called **bond pairs**. On the other hand, the valency electrons which are not involved in sharing or in the formation of covalent bonds are termed **lone pairs** or **non-bonded electrons**.

#### Conditions for formation of covalent bonds

The following conditions favour the formation of covalent bonds:

- **(i)** Electronegativity: An atom will not transfer the electron or electrons to the other atom if the electronegativity difference between the two atoms is zero or very small (less than 1.6). Such atoms prefer to share electrons, *i.e.*, form covalent bonds.
- (ii) When both the atoms are short in electrons in the valency shell in comparison to stable noble configuration, then such atoms complete the outermost shell by sharing electrons. Except hydrogen which has one electron in valency shell, such atoms have 5, 6 or 7 valency electrons. The non-metals of group VA, VIA and VIIA satisfy this condition.

# 2.13 COVALENCY

It is defined as the number of electrons contributed by an atom of the element for sharing with other atoms as to achieve noble gas configuration. It can also be defined as the number of covalent bonds formed by the atom of the element with other atoms. The usual covalency of an element except hydrogen (which has covalency 1) is equal

to 8-group number of Mendeleev's table to which an element belongs. This is true for the elements belonging to IV, V, VI and VII groups.

Element	Group	(8-Group number)	Covalency
С	IV	8 - 4 = 4	4
Si	ľV	8 - 4 = 4	4
N	V	8 - 5 = 3	3
P	$\mathbf{V}$	8 - 5 = 3	3 ·
Ο .	VI	8 - 6 = 2	2
S	VI	8 - 6 = 2	<b>2</b> ·
$\mathbf{F}$	VII	8 - 7 = 1	1 -
Cl	VII	8 - 7 = 1	1

Generally, the covalency of an element is equal to the total number of unpaired electrons in s- and p-orbitals of the valency shell.

Covalency 15 1 Hydrogen has one unpaired orbital One 2s 2p1 11 11 Fluorine has only one unpaired orbital One 11 11 Oxygen has two unpaired p-orbitals Two Nitrogen has three unpaired p-electrons 1↓ 1 Three

These four elements do not possess *d*-orbitals in their valency shell. However, the elements having vacant *d*-orbitals in their valency shell like P, S, Cl, Br, I, show variable covalency by increasing the number of unpaired electrons under excited conditions, *i.e.*, unpairing the paired orbitals and shifting the electrons to vacant *d*-orbitals. [Such a shifting is not possible in the case of H, N, O and F because *d*-orbitals are not present in their valency shell.]

Phosphorus shows 3 and 5 covalencies.

Phosphorus atom in ground state

Three unpaired electrons covalency = 3

Phosphorus atom in excited state

Five unpaired electrons covalency = 5

Sulphur atom shows 2, 4 and 6 covalencies.

Sulphur atom in ground state

Two unpaired electrons covalency = 2

Sulphur atom in excited state,

(a) When p-orbital is unpaired (first excited state.)

Four unpaired electrons covalency = 4

(b) When s- and p-orbitals are unpaired (second excited state.)  Chlorine shows 1, 3, 5 and 7	Six unpaired electrons covalency = 6 covalencies.	(b) Second excited state when two orbitals are unpaired	Five unpaired electrons covalency = 5
Chlorine atom in ground state	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	(c) Third excited state when one s-and two p-orbitals are unpaired	↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑
Chlorine atom in excited state,  (a) First excited state when p-orbital is unpaired	One unpaired electron covalency = 1  Three unpaired electrons covalency = 3	Thus, variable covalency	covalency = 7  is shown by those elements orbitals in their valency shell.

# 2.14 COVALENT COMPOUNDS

The compounds containing a covalent bond or a number of covalent bonds are termed as **covalent compounds**. Compounds such as HCl, CH<sub>4</sub>, CO<sub>2</sub>, SiO<sub>2</sub>, H<sub>2</sub>O, NH<sub>3</sub>, PCl<sub>3</sub>, SO<sub>2</sub>, etc., are some of the examples of covalent compounds. All organic compounds and the compounds formed by the combination of two different non-metals are covalent in nature.

# 2.15 COVALENT MOLECULES OF ELEMENTS

Some of elements are known to exist in molecular forms under ordinary conditions. These molecules also possess covalent bond or bonds. For example, halogens, sulphur, oxygen, nitrogen, hydrogen, phosphorus, etc., exist in molecular forms. Carbon and silicon have complex structure. In these structures the atoms are also linked by covalent bonds.

Element	Formula of the molecule	St	ructure
Hydrogen	H <sub>2</sub>	H ∗ H	H—H
Halogens (F, Cl, Br, I)	$X_2$	: X : X :	х—х
Oxygen	O <sub>2</sub>	:0::0:	0=0
Nitrogen	$N_2$	: N : N :	N≔N

Phosphorus (Every phosphorus atom is linked to other three P atoms by single covalent bonds.		P	P
	•	- P	,h,

# 2.16 CHARACTERISTICS OF COVALENT COMPOUNDS

(i) Physical state: Under the normal conditions of temperature and pressure, these exist as gases or liquids of low boiling points. This is due to the fact that very weak forces of attraction (van der Waals' forces) exist between discrete molecules.

Some exist as soft solids if their molecular masses are high. Sulphur, phosphorus, iodine are soft solids.

- (ii) Melting and boiling points: With the exception of few which have giant three dimensional structures such as diamond, carborundum (SiC), silica (SiO<sub>2</sub>), others have relatively low melting and boiling points. This is due to the presence of weak attractive forces between the molecules. On supplying heat energy, the molecules are readily pulled out from these forces and move freely having high kinetic energy.
  - (iii) Crystal structure: These are of three types.
- (a) First type: These are the crystals in which the unit is molecules. The molecules are held by van der Waals' forces. These are readily fusible and volatile. Examples are sulphur, iodine, phosphorus pentoxide, etc.
- (b) Second type: This includes crystals which have separate lattice layers. The best example of this type is graphite. Each atom has three neighbours. It is bonded to two of them by single covalent bonds and to the third by double bond. The bonds tie the atoms very tightly together into a layer. These layers can slide on one another. This accounts for the softness of graphite.
- (c) Third type: This includes crystals in which every atom is bonded to four other atoms by single covalent bonds resulting in the formation of giant structure. Examples are diamond, silicon carbide (SiC), aluminium nitride (AlN). These crystals are very hard and possess high melting points.
- (iv) Electrical conductivity: In general, covalent substances are bad conductors of electricity. Substances which have polar character like HCl in solution, can conduct electricity. Covalent solids having giant molecules, are bad conductors since they do not contain charged particles or free electrons. The graphite can conduct electricity since electrons can pass from one layer to the other.
- (v) Solubility: In general, covalent substances are insoluble in polar solvents like water but soluble in non-polar solvents like benzene, carbon tetrachloride, ether, etc. This is based on the principle, "Like dissolves like". Some of the covalent compounds like alcohols, amines dissolve in water due to hydrogen bonding. Covalent solids having giant molecules are practically insoluble in all solvents.
- (vi) Molecular reactions: Covalent substances show molecular reactions. The reaction rates are usually low because it involves two steps (i) breaking of covalent bonds of the reactants and (ii) establishing of new bonds while the ionic reactions involved only regrouping of ions.
- (vii) Isomerism: The covalent bond is rigid and directional. On account of this, there is a possibility of different arrangements of atoms in space. Covalent compounds can, thus, show isomerism (structural and space).

# 2.17

# COMPARISON BETWEEN IONIC AND COVALENT BONDS

	Ionic bond	Covalent bond
1.	Formed by the transference of electron or electrons from electro positive (metal) to electronegative (non-metal) atoms.  Such a bond is possible between dissimilar atoms.	Formed by sharing of electrons between two non-metal atoms when the electrons are equally contributed by both the atoms. Such a bond is possible between similar and dissimilar atoms.
2.	Consists of electrostatic force between atoms.	Consists of shared pair or pairs of electrons which are attracted by both the nuclei.
3.	Non-rigid and non-directional, does not cause isomerism.	Rigid and directional, causes space and structural isomerism.
4.	It is a weak bond, since the electrostatic force between the ions can be broken easily.	It is strong bond, since the paired electrons cannot be separated easily.
5.	It is polar in nature.	It is non-polar if the electronega-

Bad conductors of electricity with few exceptions having layer lat- tice structure.	
Undergo molecular reactions. Rates of reactions are low. Reactions are slow.	

# 2.19 COORDINATE BOND

Ionic compounds

It is a special type of covalent bond in which both the shared electrons are contributed by one atom only. It may be defined as "a covalent bond in which both electrons of the shared pair are contributed by one of the two atoms". Such a bond is also called as dative bond. A coordinate or a dative bond is established between two such atoms, one of which has a complete octet and possesses a pair of valency electrons while the other is short of a pair of electrons.

$$\begin{array}{c} \bullet \bullet \\ A \bullet \bullet \\ \bullet \\ \bullet \end{array} + \begin{array}{c} \bullet \times \times \\ B \times \\ \times \times \end{array} \longrightarrow \begin{array}{c} \bullet \bullet \\ \bullet \\ \bullet \\ \bullet \end{array} \begin{array}{c} \bullet \times \\ \bullet \\ \bullet \\ \times \times \end{array} \end{array}$$
 or  $A \longrightarrow B$ 

This bond is represented by an arrow  $(\rightarrow)$ .

The atom which contributes electron pair is called the **donor** while the atom which accepts it is called **acceptor**.

ote: Coordinate bond after formation is indistinguishable from a covalent bond.

The formation of a coordinate bond can be looked upon as a combination of electrovalent and covalent bonds. The formation may be assumed to have taken place in two steps:

(i) The donor atom loses one electron and transferred to acceptor atom. As a result donor atom acquires a positive charge and the acceptor atom acquires a negative charge.

(ii) These two charged particles now contribute one electron each and this pair is shared by both the atoms.

$$\begin{bmatrix} \vdots & A & \downarrow \\ \vdots & A & \downarrow \end{bmatrix} + \begin{bmatrix} \times \times \\ B & \times \\ \times \times \end{bmatrix} \longrightarrow \begin{bmatrix} \vdots & A^{+} & \vdots & B^{-} \\ B & \times \\ \times \times \end{bmatrix}$$

As the coordinate bond is a combination of one electrovalent bond and one covalent bond, it is also termed as **semi polar bond**.

The compound consisting of the coordinate bond is termed **coordinate compound**. Some examples of coordinate bond formation are given below:

(i) Combination of ammonia and boron trifluoride: Although the nitrogen atom has completed its octet in ammonia, it still has a lone pair of electrons in the valency shell which it can donate. The boron atom in boron trifluoride is short of two electrons which it accepts and completes its octet.

Any atom or ion or molecule which has one unshared electron pair which it can donate is termed as **Lewis base** while those which are capable of accepting the lone pair are termed as **Lewis acids**. In above example ammonia is a Lewis base while boron trifluoride is a Lewis acid.

Note:  $H^+$  ion and cations of transition metals such as  $Cu^{2+}$ ,  $Co^{2+}$ ,  $Fe^{2+}$ ,  $Mn^{2+}$ ,  $Cr^{3+}$ ,  $Ni^{2+}$ , etc., act as Lewis acids. The donors are also called as ligands.

(ii) Formation of ammonium ion: Hydrogen ion (H<sup>+</sup>) has no electron and thus accepts a lone pair donated by nitrogen.

(iii) Formation of  $H_2O_2$ : Oxygen in water has two lone pairs of electrons, out of which one is donated to another oxygen atom forming hydrogen peroxide.

(iv) Formation of ozone: Oxygen molecule consists of two oxygen atoms linked by a double covalent bond. Each oxygen atom has two lone pairs of electrons. When one lone pair of electrons is donated to a third oxygen atom which has six electrons, a coordinate bond is formed.

$$0 = 0 + 0 \times \times \times \longrightarrow 0 = 0 \longrightarrow 0$$
Donor Acceptor

(v) Formation of CO: Carbon has four valency electrons and oxygen has six. Two combine to form a double bond and a coordinate bond as to achieve their octet completed.

# **■** Characteristics of Coordinate Compounds

The properties of coordinate compounds are intermediate between the properties of electrovalent compounds and covalent compounds. The main properties are described below:

- (i) Physical state: These exist as gases, liquids and solids under ordinary conditions.
- (ii) Melting and boiling points: Their melting and boiling points are higher than purely covalent compounds and lower than purely ionic compounds.
- (iii) Solubility: These are sparingly soluble in polar solvents like water but readily soluble in non-polar (organic) solvents.
- (iv) Stability: These are as stable as the covalent compounds. The addition compounds are, however, not very stable. It is also a strong bond because the paired electrons cannot be separated easily.

- (v) Conductivity: Like covalent compounds, these are also bad conductors of electricity. The solutions or fused mass do not allow the passage of electricity.
- (vi) Molecular reactions: These undergo molecular reactions. The reactions are slow.
- (vii) Isomerism: The bond is rigid and directional. Thus, coordinate compounds show isomerism.
- (viii) Dielectric constant: The compounds containing coordinate bond possess high values of dielectric constants.

# 2.20 FAILURE OF OCTET RULE

There are several stable molecules known, in which the octet rule is violated, *i.e.*, atoms in these molecules have number of electrons in the valency shell either short of octet or more than octet. Some important examples are:

(i) BeCl<sub>2</sub> molecule: BeCl<sub>2</sub> (beryllium chloride) is a stable molecule. Be atom forms two single covalent bonds with two chlorine atoms, *i.e.*, it attains four electrons in the outer shell.

$$_{\times}$$
 Be  $_{\times}$  +2 •Cl :  $\longrightarrow$  Cl  $_{\times}$  Be  $_{\times}$  Cl  $_{\times}$  Cl -Be-Cl

(ii) BF<sub>3</sub> molecule: Boron atom forms three single covalent bonds with three fluorine atoms, *i.e.*, it attains six electrons in the outer shell.

(iii) PCl<sub>5</sub> molecule: Phosphorus atom have five electrons in valency shell. It forms five single covalent bonds with five chlorine atoms utilising all the valency electrons and thereby attains 10 electrons in the outer shell.

(iv)  $SF_6$  molecule: Sulphur atom has six electrons in the valency shell. It forms six single covalent bonds with six fluorine atoms utilising all the valency electrons and thereby attains 12 electrons in the outer shell.

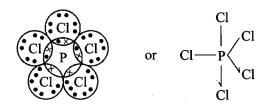

(v)  $IF_7$  molecule: Iodine forms seven single covalent bonds with seven fluorine atoms utilising 7 valency electrons. The iodine atom attains 14 electrons in outermost shell.

To explain the above abnormalities, the following two concepts were introduced:

# 1. Sugden's concept of singlet linkage:

Sugden introduced the idea of singlet linkage in favour of octet rule. According to this concept the maximum number of electrons in the outermost shell of any atom cannot exceed eight. In the molecules of PCl<sub>5</sub>, SF<sub>6</sub>, IF<sub>7</sub>, etc., the central atom is linked with some of the combining atoms by single-electron bonds, called **singlet linkage** while the remaining atoms are linked by the normal two electrons bonds. The bond is represented by a half arrow ( ) with the head pointing from donor towards the acceptor.

In PCl<sub>5</sub>, three chlorine atoms are linked by normal covalent bonds and two chlorine atoms are linked by singlet linkages, thus, phosphorus achieves 8 electrons in the outermost shell.

This structure indicates that the nature of two chlorine atoms is different than the other three as singlet linkage is weaker than normal covalent bond. The above observation is confirmed by the fact that on heating, PCl<sub>5</sub> dissociates into PCl<sub>3</sub> and Cl<sub>2</sub>.

$$PCl_5 \rightleftharpoons PCl_3 + Cl_2$$

Similarly, in SF<sub>6</sub>, four singlet linkages are present while in IF<sub>7</sub>, six singlet linkages are present.

# 2. Sidgwick's concept of maximum covalency

This rule states that the covalency of an element may exceed four and octet can be exceeded. The maximum covalency of an element actually depends on the period of periodic table to which it belongs. The maximum covalency of the elements is tabulated below:

Period	Elements	Maximum covalency	No. of electrons in the outermost orbit
1st	Н	2	4
2nd	Li to F	4	8
3rd	Na to Cl	. 6	12
4th	K to Br	6	12
$^{5 ext{th}}$ $\}$	Rb onwards and rest of	8	16
6th	the elements	}	,

This rule explains the formation of PCl<sub>5</sub> and SF<sub>6</sub>. This also explains, why nitrogen does not form NF5 or NCl5 because nitrogen belongs to second period and the maximum covalency of nitrogen is four.

# 2.21 LEWIS FORMULAE FOR MOLECULES AND POLYATOMIC IONS

Lewis electron-dot formula of a molecule or a polyatomic ion shows how atoms are bonded with each other. Bonding electrons are indicated either by two dots or by a dash. For instance, a water molecule can be represented by either of the following two diagrams.

Lewis dot formula

Dash formula

Lewis dot formulae show only the number of valency electrons, the number and kinds of bonds, but do not depict the three dimensional shapes of molecules and polyatomic ions. Lewis formulae are based on the fact that the representative elements achieve a noble gas configuration in most of their compounds, i.e., 8 electrons in their outermost shell (except for H<sub>2</sub>, Li<sup>+</sup> and Be<sup>2+</sup> ions which have 2 electrons).

The following steps are followed in constructing dot formulae for molecules and polyatomic ions:

- (i) Write a symmetrical 'skeleton' for the molecules and polyatomic ions.
- (a) The least electronegative element is usually taken as the central element except H.

For example: CO<sub>2</sub> has the skeleton OCO.

(b) Oxygen atoms do not bond to each other except in  $O_2$ , O<sub>3</sub>, the peroxides and superoxides. The phosphate ion

$$(PO_4^{3-})$$
 has the skeleton O  $\stackrel{\circ}{P}$  O.

(c) Hydrogen actually bonds to an oxygen atom and not to the central atom in ternary acids (oxyacids).

For example: Nitrous acid HNO2, has the skeleton HONO. However, there are exceptions to this rule, such as for H<sub>3</sub>PO<sub>2</sub>, the skeleton is H P OH.

H

(d) For polycentred species such as C2H4, the most HH

symmetrical skeleton is used. C C is the skeleton for C<sub>2</sub>H<sub>4</sub>. HH

(ii) Calculate the number of electrons available in the valency shell of all the atoms.

For negatively charged ions add to the total number of electrons equal to the charge on the anion and for positively charged ions, subtract the number of electrons equal to the charge on the cations.

The total number of electrons calculated in this way is represented by symbol A.

For example: A for  $H_2SO_4$ 

 $A = 2 \times 1$  (for hydrogen atoms) + 1 × 6 (for S atom)

 $+4 \times 6$  (for O atoms)

= 2 + 6 + 24

= 32 electrons.

A for PO4 ion

 $A = 1 \times 5$  (for P atom) +  $4 \times 6$  (for O atoms)

+ 3 (for charge)

= 5 + 24 + 3

= 32 electrons.

A for NH4 ion

 $A = 1 \times 5$  (for nitrogen atom) +  $4 \times 1$  (for H atoms)

- 1 (for positive charge)

= 5 + 4 - 1

= 8 electrons.

(iii) Calculate the total number of electrons needed by all atoms to achieve noble gas configuration. This number is represented by N.

For example: N for  $H_2SO_4$ 

$$N = 2 \times 2 + 8 \times 1 + 8 \times 4$$

= 4 + 8 + 32

= 44 electrons.

(iv) Calculate the total number of electrons shared. This is represented by S, which is equal to N-A.

For example: S for  $H_2SO_4$ 

S = N - A

= 44 - 32

= 12 electrons.

(v) Place the shared pair of electrons into the skeleton, using double and triple bonds only when necessary.

## for example:

Skeleton

Dot formula

Dash formula

(vi) Place the additional unshared (lone) pairs of electrons to fill the octet to every atom except hydrogen which can have only 2 electrons as the total comes equal to A as calculated in step (ii).

## For H<sub>2</sub>SO<sub>4</sub>

# SOME WORKED EXAMPLES

**Example 1.** Write the Lewis dot formula and dash formula for CO<sub>2</sub>.

**Solution:** Step (i) The skeleton is OCO.

Step (ii)

 $A = 1 \times 4$  (for C) + 2 × 6 (for O) = 4 + 12 = 16 electrons Step (iii)

 $N = 1 \times 8$  (for C) + 2 × 8 (for O) = 8 + 16 = 24 electrons Step (iv) S = N - A = 24 - 16 = 8 electrons shared

Step (v)

O::C::O

Step (vi) : O:: C:: O:

**Example 2.** Write the Lewis dot formula and dash formula for the  $SO_4^{2-}$  ion.

**Solution:** Step (i) The skeleton  $\begin{bmatrix} O \\ O S O \\ O \end{bmatrix}^{2-}$ 

Step (ii)

 $A = 1 \times 6$  (for S) +  $4 \times 6$  (for O) + 2 (for negative charge) = 6 + 24 + 2

= 32 electrons

Step (iii)

 $N = 1 \times 8 \text{ (for S)} + 4 \times 8 \text{ (for O)}$ 

= 8 + 32

= 40 electrons

Step (iv) S = N - A = 40 - 32 = 8 electrons shared

Step (v) 
$$O: S: O^{2-} O - S - O^{2-} O$$

**Example 3.** Write the Lewis dot formula or dash formula for the  $CO_3^2$  ion.

**Solution:** Step (i) Skeleton O C  $O^{2-}$ 

Step (ii)

 $A = 1 \times 4$  (for C) +  $3 \times 6$  (for O) + 2 (for negative charge)

= 4 + 18 + 2

= 24 electrons

Step (iii)

 $N = 1 \times 8$  (for C) +  $3 \times 8$  (for O)

= 8 + 24

= 32 electrons

Step (iv)

S = N - A

= 32 - 24

= 8 electrons shared (4 pairs shared)

Step (vi) 
$$: O: C:: O:^{2-}$$
 or  $: O - C = O^{2-}$

  $\stackrel{\times}{\times}$   $\stackrel{\times}$ 

# 2.22 FORMAL CHARGE

In case of the polyatomic ions, the net charge is possessed by an ion as a whole and not by a particular atom. However, for some purposes each atom in a polyatomic ion or molecule is assigned a **formal charge**. It is defined as the difference between the number of valence electrons in an isolated (*i.e.*, free) atom and the number of electrons assigned to that atom in a Lewis structure. The counting of electrons is based on the assumption that the atom in the molecule owns one electron of each shared pair and both the electrons of a lone pair.

Formal charge on an atom = total number of valence electrons in the free atom - total number of non bonding (lone pair) electrons -  $\frac{1}{2}$  total number of bonding (shared) electrons

The concept of formal charge can be explained by nitrous oxide molecule,  $N_2O$ . The electron dot structure for  $N_2O$  can be written as :

Using the given relationship, the formal charges on the three atoms can be calculated as follows:

## (a) Terminal nitrogen atom:

Valence electrons = 5

Lone pair = one (two electrons)

Total number of bonding electrons = 6

Formal charge 
$$= 5 - 2 - \frac{1}{2} \times 6 = 0$$

#### (b) Central nitrogen atom:

Valence electrons = 5

Lone pair = nil

Total number of bonding electrons = 8

Formal charge =  $5 - \frac{1}{2} \times 8 = +1$ 

#### (c) Terminal oxygen atom:

Valence electrons = 6

Lone pair = three (six electrons)

Total number of

bonding electrons = 2

Formal charge = 
$$6 - 6 - \frac{1}{2} \times 2 = -1$$

Thus, the structure can be written as follows:

The advantage of calculation of formal charges is that it helps to select the most stable structure of the molecule or ion. The most stable structure is the one which has the smallest formal charges on the atoms or zero formal charges on the atoms. Negative formal charges should appear on the most electronegative atoms. Adjacent atoms in the structure should not carry the formal charges of same sign. The total formal charges on the atoms in a Lewis structure must be zero for a neutral molecule and must equal to net charge for a polyatomic ion.

**Example 4.** Calculate the formal charges on atoms in (a)  $CS_2$  and (b)  $CO_3^{2-}$  ion

Solution: (a) Lewis structure of CS<sub>2</sub> is

$$\dot{S} = C = \dot{S}$$

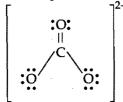

Formal charge on each sulphur atom = valence electrons – lone pair electrons – (1/2) bonding electrons

$$=6-4-(1/2)\times 4=0$$

Formal charge on carbon atom = valence electrons – lone pair electrons – 1/2 bonding electrons

$$= 4 - 0 - (1/2) \times 8 = 0$$

(b) Lewis structure of  $CO_3^{2-}$  ion is

Formal charge on carbon atom =  $4 - (1/2) \times 8 = 0$ Formal charge on double bonded O atom

$$=6-4-(1/2)\times 4=0$$

Formal charge on single bonded O atom

$$= 6 - 6 - (1/2) \times 2 = -1$$

**Example 5.** Select the most stable correct structure of COCl<sub>2</sub>

**Solution :** (a) FC on O atom =  $6 - 6 - (1/2) \times 2 = -1$ 

FC on C atom =  $4 - 0 - (1/2) \times 8 = 0$ 

FC on Cl atom =  $7 - 6 - (1/2) \times 2 = 0$ 

FC on Cl atom =  $7 - 4 - (1/2) \times 4 = +1$ 

(b) FC on C atom =  $4 - 4 - (1/2) \times 4 = -2$ 

FC on O atom =  $6 - 0 - (1/2) \times 8 = +2$ 

FC on Cl atom =  $7 - 6 - (1/2) \times 2 = 0$ 

(c) FC on O atom =  $6 - 4 - (1/2) \times 4 = 0$ 

FC on C atom =  $4 - 0 - (1/2) \times 8 = 0$ 

FC on Cl atom =  $7 - 6 - (1/2) \times 2 = 0$ 

Structure (c) with formal charges of zero is the most stable correct structure.

# 2.23 POLARITY OF COVALENT BOND

In all homonuclear diatomic molecules like hydrogen molecule  $(H_2)$ , chlorine molecule  $(Cl_2)$ , fluorine molecule  $(F_2)$ , oxygen molecule  $(O_2)$ , the electron pair or pairs is shared equally between the two atoms. This means that shared electrons are equally attracted to both the nuclei and therefore spend equal amounts of time near each nucleus. As a result, the molecule is **neutral** or **non-polar**.

When the heteronuclear diatomic molecule is considered the situation is not simple. Electronegativity is defined as the tendency of an atom to attract electrons towards itself in a chemical bond. Thus, in heteronuclear diatomic molecule, both the atoms joined by the covalent bond possess different electronegativity. As a result, the atom having higher value of electronegativity attracts the shared electron pair much more strongly than the other atom. For example, in HF the electron pair is more attracted towards F as it is more electronegative than hydrogen. Due to this, the fluorine end of the molecule appears negative and the hydrogen end positive. Such molecules having two oppositely charged poles are called polar molecules and the bond is said to be a polar covalent bond.

A covalent bond, in which electrons are shared unequally and the bonded atoms acquire a partial positive and negative charge, is called a polar covalent bond or a covalent bond between two dissimilar atoms is a polar covalent bond.

Two kinds of notation are used to indicate a polar covalent bond.

Polar covalent bonds may be thought of as being intermediate between the non-polar bonds and pure ionic bonds.

Bond polarity is described in terms of ionic character which usually increases with increasing difference in the electronegativity (EN) between bonded atoms.

Ionic character decreases as the difference in electronegativity decreases

Pauling has estimated the approximate percentage of ionic character in various A—B covalent bonds from the ( $X_A$  –  $X_B$ ) values, *i.e.*, electronegativity difference of the two atoms forming the covalent bond.

$X_A - X_B$		Percentage of ionic character	Nature of A—B bond
	0	0	Purely covalent
	0.1 to 0.8	0.5 - 15	Covalent
	0.9 to 1.8	19 - 47	Polar covalent
	1.9	50	50% ionic and 50% covalent
	2 to 3.2	55-93	Ionic

Hanny and Smyth gave the following equation for calculating the percentage of ionic character in A—B bond on the basis of the values of electronegativity of the atoms A and B. Percentage of ionic character =  $[16(X_A - X_B) + 3.5(X_A - X_B)^2]$ 

This equation gives approximate calculation of percentage of ionic character, *e.g.*, 50% ionic character corresponds to  $(X_A \sim X_B)$  equal to 2.1.

**Example 6.** Calculate the percentage of ionic character in Cs—Cl bond in CsCl molecule. The electronegativity values of Cs and Cl are 0.7 and 3.0 respectively.

**Solution :** 
$$X_A - X_B = X_{CI} - X_{Cs} = (3.0 - 0.7) = 2.3$$
  
Percentage of ionic character in Cs—Cl bond  
=  $[16 \times 2.3 + 3.5 \times (2.3)^2]$   
=  $[36.8 + 18.51]$   
=  $55.31$ 

**Example 7.** Arrange molecules HF, HCl, HBr and HI in the decreasing order of the percentage of ionic character. Electronegativity values are as follows:

$$H = 2.1$$
,  $F = 4.0$ ,  $Cl = 3.0$ ,  $Br = 2.8$ ,  $I = 2.5$   
Solution: Percentage of ionic character in H—F  
 $= [16 \times 1.9 + 3.5 \times (1.9)^2]$   
 $= 43$   
% ionic character in H—Cl =  $[16 \times 0.9 + 3.5 \times (0.9)^2]$   
 $= 17.2$   
% ionic character in HBr =  $[16 \times 0.7 + 3.5 \times (0.7)^2]$   
 $= 12.9$   
% ionic character in HI =  $[16 \times 0.4 + 3.5 \times (0.4)^2]$   
 $= 7.0$   
Order HF > HCl > HBr > HI

# 2.24 DIPOLE MOMENT

Difference in polarities of bonds is expressed on a numerical scale. The polarity of a molecule is indicated in terms of **dipole moment** ( $\mu$ ). To measure dipole moment, a sample of the substance is placed between two electrically charged plates. Polar molecules orient themselves in the electric field causing the measured voltage between the plates to change.

The dipole moment is defined as the product of the distance separating charges of equal magnitude and opposite sign, with the magnitude of the charge. The distance between the positive and negative centres is called the bond length. Thus,

$$\mu = \text{electric charge} \times \text{bond length}$$

$$= q \times d$$

As q is in the order of  $10^{-10}$  esu and d is in the order of  $10^{-8}$  cm,  $\mu$  is in the order of  $10^{-18}$  esu cm. Dipole moment is measured in 'Debye' unit (D).

$$1 D = 10^{-18}$$
 esu cm =  $3.33 \times 10^{-30}$  coulomb metre

Generally, as electronegativity difference increases in diatomic molecules, the value of dipole moment increases. Greater the value of dipole moment of a molecule, greater the polarity of the bond between the atoms.

Molecule	HI	H-Br	H—C1	H-F
% ionic character	7	12.9	17.2	43
$(X_A - X_B)$	0.4	0.7	0.9	1.9
Dipole moment-	0.38 D	0.78 D	1.03 D	1.92 D

Dipole moment is a vector quantity, *i.e.*, it has both magnitude as well as direction. The overall value of the dipole moment of a polar molecule depends on its geometry and shape, *i.e.*, vectorial addition of dipole moment of the constituent bonds. A symmetrical molecule is non-polar even though it contains polar bonds. For example, CO<sub>2</sub>, BF<sub>3</sub>, CH<sub>4</sub>, CCl<sub>4</sub> being symmetrical molecules have zero resultant dipole moments and hence are non-polar since dipole moments summation of all the bonds present in the molecule cancel each other. Dipole moment is usually indicated by an arrow having + on the tail (+—), above the polar bond and pointing towards the negative end.

$$0 \stackrel{\longleftarrow}{=} C \stackrel{\longleftarrow}{=} 0 \qquad \qquad \downarrow \\ F \stackrel{\longrightarrow}{=} B \qquad \qquad \downarrow \\ F \stackrel{\longleftarrow}{=} C \stackrel{\longleftarrow}{\longrightarrow} H$$

Unsymmetrical non-linear polyatomic molecules always have net value of dipole moment, thus such molecules are polar in nature. H<sub>2</sub>O, CH<sub>3</sub>Cl, NH<sub>3</sub>, etc., are polar molecules as they have some positive values of dipole moments.

$$H = 0$$

$$H = 1.84D$$

$$Water \mu = 1.84D$$

$$Cl$$

$$H = 1.60D$$

$$H = 1.60D$$

$$H = 1.60D$$

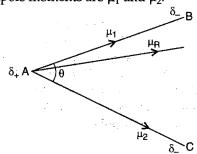

$$H = 1.60D$$

$$H = 1.46D$$

$$H = 1.46D$$

# **■** Calculation of Resultant Bond Moments

Let AB and AC are two polar bonds inclined at an angle  $\theta$ , their dipole moments are  $\mu_1$  and  $\mu_2$ .

Resultant dipole moment may be calculated using vectorial method.

$$\mu_R = \sqrt{\mu_1^2 + \mu_2^2 + 2\mu_1\mu_2\cos\theta}$$

when,  $\theta = 0$ , the resultant is maximum.

$$\mu_R = \mu_1 + \mu_2$$
when,  $\theta = 180^\circ$ , the resultant is minimum.

 $\mu_R = \mu_1 \sim \mu_2$ 

#### **DIPOLE MOMENT OF SOME COMMON SUBSTANCES**

Compound	Dipole moment (D)	Compound	Dipole moment (D)	Compound	Dipole moment (D)
HF	1.92	NH <sub>3</sub>	1.46	CH <sub>3</sub> Cl	1.86
HCl	1.03	H <sub>2</sub> O	1.84	C <sub>2</sub> H <sub>5</sub> OH	1.68
HBr	0.78	H <sub>2</sub> S	0.92	CH <sub>3</sub> COCH <sub>3</sub>	1.30
HI	0.38	SO <sub>2</sub>	1.60	C <sub>6</sub> H <sub>5</sub> Cl	1.57

# **■** Applications of Dipole Moment

- (i) To decide polarity of the molecule: Molecules having zero dipole moment\* are said to be non-polar molecules and those having  $\mu_R \neq 0$  are polar in nature.
- (ii) To determine percentage of ionic character: The value of dipole moment can be used for determining the amount of ionic character in a bond. Consider a diatomic molecules say HCl. Suppose this molecule is completely ionic. Under this condition  $H^+$  and  $Cl^-$  ions would bear a unit charge equal to  $4.8 \times 10^{-10}$  esu and the bond distance between H and Cl atoms = 1.27 Å.

Thus, theoretical value of  $\mu$  (considering molecule completely ionic)

$$= 4.8 \times 10^{-10} \times 1.27 \times 10^{-8} = 6.09 \text{ D}$$

Dipole moment of HCl is also determined experimentally. Let the experimental value be 1.03 D.

Percentage of ionic character in H—Cl bond in HCl molecule

= Experimental value of 
$$\mu$$
  
Theoretical value of  $\mu$  × 100 =  $\frac{1.03}{6.09}$  × 100 = 16.9

Thus, percentage of ionic character

Experimental value of dipole moment

- Theoretical value of dipole moment × 100
- (iii) To determine geometry of molecules: The values of dipole moments provide valuable information about the structure of molecules.
- (a)  $CO_2$ ,  $CS_2$  molecules are linear as values of their dipole moments are zero.
- (b)  $H_2O$  is not a linear molecule as it has dipole moment. Actually, it has V-shaped structure and the bond angle is  $105^\circ$ . Similarly,  $SO_2$  has a bent structure.
- (c) In ammonia, three hydrogen atoms do not lie symmetrically with respect to nitrogen as it has dipole moment. It has pyramidal structure.

#### MOLECULAR GEOMETRY AND DIPOLE MOMENT

General formula	Molecular geometry	Dipole moment	Example
$\overline{AX}$	Linear	May be non-zero	HF, HCl
$AX_2$	Linear	Zero	CO <sub>2</sub> ,CS <sub>2</sub>
	Bent or V-shape	Non-zero	$H_2O$ , $NO_2$
$AX_3$	Triangular planar	Zero	BF <sub>3</sub>
	Pyramidal	Non-zero	NH <sub>3</sub> , PCl <sub>3</sub>
	T-shape	Non-zero	ClF <sub>3</sub>
$AX_4$	Tetrahedral	Zero	CH <sub>4</sub> , CCl <sub>4</sub>
	Square planar	Zero	XeF <sub>4</sub>
	See-saw	Non-zero	SF <sub>4</sub> , TeCl <sub>4</sub>
$AX_5$	Trigonal bipyramidal	Zero	PCl <sub>5</sub>
	Square pyramidal	Non-zero	BrCl <sub>5</sub>
$AX_6$	Octahedral	Zero	SF <sub>6</sub>
	Distorted octahedral	Non-zero	XeF <sub>6</sub>
$AX_7$	Pentagonal bipyramidal	Zero	IF <sub>7</sub>

(iv) To distinguish *cis* and *trans* forms of geometrical isomers: Experimental values of dipole moment of the isomers (*cis* and *trans*) are determined. The *trans* isomer usually possesses either zero dipole moment or very low value in comparison to *cis* form.

It should be noted that if two groups have opposite inductive character then *trans* isomer will have greater dipole moment of,

 $CH_3$  H

 $CH_3$  H

(v) To determine orientation in benzene ring: Dipole moment is useful to ascertain the orientation of substituents. The greater the dipole moment, the greater is the asymmetry. In general, dipole moment follows the order:

<sup>\*</sup>In the symmetrical molecules having polar bonds, centre of positive and negative poles coincides leading to zero dipole moment.

In ortho isomers, experimental value of dipole moment is found different from theoretical value of dipole moment. This difference is due to dipole-dipole interaction of two groups.

(vi) Bond moment: The contribution of individual bond in the dipole moment of a polyatomic molecule is termed bond moment. The measured dipole moment of water molecule is 1.85 D. This dipole moment is the vectorial sum of the individual bond moments of two O—H bonds having bond angle 104.5°.

Thus, 
$$\mu_{\text{obs}} = 2\mu_{\text{O}}$$
 cos 52.25  
or  $1.85 = 2\mu_{\text{O}}$  × 0.6129  
 $\mu_{\text{O}}$  = 1.51 D

#### Conclusions

- (i) Dipole moment ∞ Electronegativity difference For example, HF > HCl > HBr > HI
- (ii) Dipole moment 

  Number of lone pairs of electrons
  For example, HF > H<sub>2</sub>O > NH<sub>3</sub>

  Fluorine has 3 lone pairs, oxygen has 2 lone pairs
  and nitrogen has one lone pair.
- (iii) Dipole moment  $\propto 1/\theta$

X X 60° 120° 180°

(iv) Homoatomic molecules and molecules having normal shapes such as linear, trigonal, tetrahedral possess zero dipole moment.

For example, Cl<sub>2</sub>, N<sub>2</sub>, O<sub>2</sub>, CO<sub>2</sub>, BCl<sub>3</sub>, CCl<sub>4</sub>, SiCl<sub>4</sub>

- (v) Molecules having distorted shapes like angular, pyramidal, sea-saw, etc, show dipole moments. For example, H<sub>2</sub>O, SO<sub>2</sub>, H<sub>2</sub>S, NH<sub>3</sub>, SF<sub>4</sub>
- (vi) Dipole moment of a cis-alkene is more than transalkene. In trans-alkenes, it is zero due to similar groups (symmetry).
  It should be noted that if two groups have opposite inductive character, then trans isomer will have

greater dipole moment.

# 2/25 POLARISATION (CHANGE OF IONIC CHARACTER TO COVALENT CHARACTER)

When two oppositely charged ions of unequal size approach each other closely (during formation of an electrovalent bond), the ion smaller in size attracts outermost electrons of the other ion and repel its nuclear charge. The net result is distortion or polarisation of the bigger ion. This distortion is usually done by the cation as its size is smaller than the anion. The electron cloud of anion no longer remains symmetrical but is elongated towards the cation. The ability of a cation to polarise the nearby anion is called its **polarising power** and the tendency of an anion to get distorted or

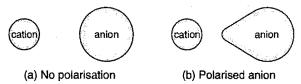

Fig. 2.6 Representation of Polarisation

deformed or polarised by the cation is called its **polarisability**. Due to polarisation, sharing of electrons occur between two ions to some extent and the bond shows some covalent character. This is shown in Fig.2.6.

The magnitude of polarisation depends upon a number of factors or the increased covalent character is favoured by a number of factors. These factors were suggested by Fajan and are known as Fajan's rules.

(i) Charge on cation: As the charge on the cation increases, its tendency to polarise the anion increases. This brings more and more covalent nature in the electrovalent compound.

For example, in the case of NaCl, MgCl<sub>2</sub> and AlCl<sub>3</sub> the polarisation increases, thereby covalent character becomes more and more as the charge on the cation increases.

Cation	Cation charge	Formula of the chloride	Melting point of t chloride, °C	
Na <sup>+</sup>	+1	NaCl	800	Covalent
Mg <sup>++</sup>	+2	MgCl <sub>2</sub>	712	character
$Al^{+++}$	+3	AlCl <sub>3</sub>	Sublimes	increases

Similarly, lead forms two chlorides  $PbCl_2$  and  $PbCl_4$  having charges +2 and +4 respectively.  $PbCl_4$  shows covalent nature.

In general, if a metal forms more than one halide, the halide having higher charge on the cation (i.e., higher oxidation state) is usually more covalent in nature in comparison to halide having a cation with lower charge, i.e., lower oxidation state or in other words, the melting point of the halide having higher oxidation state is less than the melting point of halide having lower oxidation state.

(ii) Size of the cation: Polarisation of the anion increases as the size of the cation decreases, *i.e.*, the electrovalent compounds having smaller cations show more of the covalent nature. For example, in the case of halides of alkaline earth metals, the covalent character decreases.

Cation	Radius of the cation Å	Formula of the chloride	Melting point of the chloride, °C	
Be <sup>2+</sup>	0.31	BeCl <sub>2</sub>	405	t te
$Mg^{2+}$ $Ca^{2+}$	0.65	MgCl <sub>2</sub>	712	ent ter ses point
	0.99	CaCl <sub>2</sub>	772	Covalent character increases increases slting po
Sr <sup>2+</sup>	1.13	SrCl <sub>2</sub>	872	getti ji g C
Ba <sup>2+</sup>	1.35	BaCl <sub>2</sub>	960	2

Low melting point indicates more covalent nature.

(iii) Size of anion: The larger the size of the anion, more easily it will be polarised by the cation, *i.e.*, as the size of the anion increases for a given cation, the covalent character increases. For example, in the case of halides of calcium, the covalent character increases from  $F^-$  anion to  $I^-$  anion.

Cation	Anion	Anion size Å	Formula of the halide	Melt	ing point of the halide, °C
Ca <sup>2+</sup>	F-	1.36	CaF <sub>2</sub>	1932	nt ss ss oint
	Cl <sup>-</sup>	1.81	CaCl <sub>2</sub>	772	alent racter eases ng poi
	Br <sup></sup>	1.95	CaBr <sub>2</sub>	730	Cov Shar incre settin
	I-	2.16	CaI <sub>2</sub>	575	Ţ , "ŢŞ ,

Similarly, in the case of trihalides of aluminium, the covalent character increases with increase in size of halide anion.

(iv) Configuration of cation: The cations with 18 electrons in outermost shell bring greater polarisation of the anion than those with inert gas configuration even if both the cations have same size and same charge. For example, CuCl is more covalent than NaCl.

Cu <sup>+</sup> Ion	2, 8, 18	Na <sup>+</sup> 2, 8
Size	0.96 Å	0.95 Å
Malima maint	C-C1 4429C	NI-C1 000

Melting point CuCl, 442°C NaCl, 800°C Cations having more of core electrons are more

Cations having more of core electrons are more polarising and thus, favour covalency.

In general, all those electrovalent compounds having high values of polarisation (more covalent character) are found to be less soluble in water but more soluble in organic solvents. The following examples support this view:

- (i) Sulphides are less soluble in water than oxides of the same metal.
  - (ii) Lithium salts are soluble in organic solvents.
- (iii) Beryllium compounds are less soluble than corresponding other alkaline earth metal compounds.
- (iv) The solubility of aluminium halides decreases from AlF<sub>3</sub> to AlI<sub>3</sub>.

# Points to Remember

- (i) On moving down a group, the polarising power of the cations goes on decreasing.
- (ii) Polarising power of the cations increase in moving left to right in a period.
- (iii) The polarisability of the anions by a given cation decreases in moving left to right in a period.
- (iv) The polarisability of the anions by a given cation increases moving down a group.
- (v) Increase of polarisation brings more of covalent character in an ionic compound. The increased covalent character is indicated by the decrease in melting point of the ionic compound. Examples:

Polarisation increases →
Covalent character increases →

Melting point decreases -----

# 2.26 HYDROGEN BONDING

In 1920, **Latimer** and **Rodebush** introduced the idea of "hydrogen bond" to explain the nature of association in liquid state of substances like water, hydrogen fluoride, ammonia, formic acid, etc. In a hydrogen compound, when hydrogen is bonded to highly electronegative atom (such as F, O, N) by a covalent bond, the electron pair is attracted towards electronegative atom so strongly that a dipole results, *i.e.*, one end carries a positive charge (H–end) and other end carries a negative charge (X–end).

If a number of such molecules are brought nearer to each other, the positive end of one molecule and negative end of the other molecule will attract each other and weak electrostatic force will develop. Thus, these molecules will associate together to form a cluster of molecules.

The attractive force that binds hydrogen atom of one molecule with electronegative atom of the other molecule of the same or different substance is known as **hydrogen bond**. This bond is represented by 3 dotted line.

Hydrogen bonding is of two types.

(a) Intermolecular hydrogen bonding: This type of bonding results between the positive and negative ends of different molecules of the same or different substances.

## Examples 8.

#### (i) Hydrofluoric acid:

#### (ii) Ammonia:

#### (iii) Water:

(iv) Formic acid:

#### (v) p-chlorophenol:

$$--\frac{\delta_{-}}{Cl} \longrightarrow O-H--Cl \longrightarrow O-H--Cl$$

$$\longrightarrow O-H--Cl$$

$$\longrightarrow O-H--Cl$$

This type of hydrogen bonding increases the boiling point of the compound and also its solubility in water. The increase in boiling point is due to association of several molecules of the compound.

Intermolecular hydrogen bond is also responsible for increase in the viscosity. Greater is the extent of hydrogen bonding more is the viscosity.

C.P. stands for centipoise.

(b) Intramolecular hydrogen bonding: This type of bonding results between hydrogen and an electronegative element both present in the same molecule. This type of bonding is generally present in organic compounds. Examples are *o*-chlorophenol, *o*-nitrophenol, *o*-hydroxy benzoic acid, etc.

This type of bonding decreases the boiling point of the compound. The solubility of the compound also decreases.

# ■ Nature and Importance of Hydrogen Bond

- (i) Hydrogen bond is merely an electrostatic force rather than a chemical bond.
  - (ii) Hydrogen bond never involves more than two atoms.
- (iii) Bond energy of hydrogen bond is in the range of 3 to 10 kcal/mole (10 to 40 kJ per mole), *i.e.*, about 1/10 the energy of a covalent bond (strength 50–100 kcal mol<sup>-1</sup>).
- (iv) With the increase of electronegativity and decrease in size of the atom to which hydrogen is covalently linked, the strength of the hydrogen bond increases. It is evident from the energies of hydrogen bonds in the three elements.

$$H - F - - - H > H - O - - - H > H - N - - - H$$
10 kcal mol<sup>-1</sup>
7 kcal mol<sup>-1</sup>
2 kcal mol<sup>-1</sup>

Energy of some hydrogen bonds in neutral molecules are tabulated below:

Bond	Average bond energy kJ mol <sup>-1</sup>
F—HO	40–45
F—HF	2325
O-H-O	20–30
OHS	15–20
OHF	12–15
NHN	12–25
NHO	20–25

(v) All the three atoms in X—H- - - X lie in the straight line.

Without hydrogen bonding water would have existed as a gas like hydrogen sulphide. In that case, no life would have been possible on this earth. Hydrogen bonding exists in molecules of living organisms. It exists in various tissues, blood, skin, bones, etc. The cotton, silk or synthetic fibres possess rigidity and tensile strength due to hydrogen bonding. The stickiness of glue or honey is also due to hydrogen bonding. Thus, hydrogen bonding has great importance in everyday life.

# ■ Properties Explained by Hydrogen Bonding

- (a) High boiling and melting points of  $NH_3$ ,  $H_2O$  and HF in comparison to hydrides of other elements of V, VI and VII groups to which N,O and F belong, respectively, are due to hydrogen bonding.  $H_2O$  exists in liquid state under ordinary condition while  $H_2S$  in gaseous state as hydrogen bonding exists in water and no hydrogen bonding exists in  $H_2S$ .
- (b) Unique properties of water and ice are due to hydrogen bonding. Density of ice is less than water and water contracts when heated between 0°C to 4°C. These two unique properties are on account of open cage structure of ice due to hydrogen bonding.
- (c) Strength of certain acids and bases can be explained on the basis of hydrogen bonding.
- (d) Solubility: A substance is said to be insoluble in water if it does not form hydrogen bonding with water. The organic compound like alkanes, alkenes, ethers, etc., are insoluble in water as they do not form hydrogen bonding with water, while alcohols and acids are soluble because they readily form hydrogen bonds with water.

Note: Chlorine has the same electronegativity as nitrogen but does not form strong hydrogen bonds. This is because of the larger size than that of nitrogen with the result that its electrostatic attractions are weak.

# 2.27 MODERN CONCEPT OF COVALENT BOND

The Lewis or octet concept does not explain the following points:

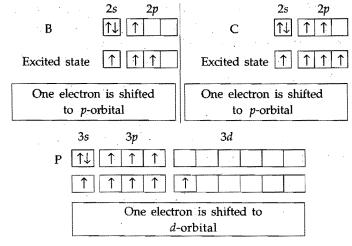

- (i) The cause of covalent bond formation.
- (ii) Nature of the forces operating between the atoms forming a covalent bond.
- (iii) Why different amounts of energies released during the formation of different molecules.
  - (iv) Shape and geometry of molecules.
- (v) Why the molecules are stable in which central atoms have either less than 8 electrons or more than 8 electrons in the outermost shell.

To explain the above limitations, the following two theories based on quantum mechanics have been proposed.

- (a) The valence bond theory and
- (b) Molecular orbital theory.

The valence bond theory: This theory was presented by Heitler and London, in 1927, to explain how a covalent bond is formed. This theory was extended by Pauling and Slater, in 1931. The main points of the theory are:

- (i) A covalent bond is formed by overlapping of atomic orbitals of valency shell of the two atoms\*.
- (ii) Only half filled atomic orbitals, *i.e.*, orbitals singly occupied can enter into overlapping process. The resulting bond acquires a pair of electrons with opposite spins.
- (iii) The atoms with half filled orbitals must come closer to one another with their axes in proper directions for overlapping.
- (iv) As a result of overlapping, there is maximum electron density somewhere between the two atoms. A large part of bonding force comes into existence from the electrostatic attraction between the nuclei and the accumulated electron cloud between them.
- (v) Greater the overlapping, higher is the strength of the chemical bond. The amount of energy released per mole during overlapping is termed bond energy. This energy stabilises the system. Hence, the molecule formed has less energy and consequently more stability than the isolated atoms.
- (vi) Electrons which are already paired in valency shell can enter into bond formation if they can be unpaired first and shifted to vacant orbitals of slightly higher energy of the same main energy shell (valency shell). This point explains the trivalency of boron, tetravalency of carbon, pentavalency of phosphorus, hexavalency of sulphur and heptavalency of halogens (Cl, Br, I) inspite of the fact that these atoms have paired orbital or orbitals in the valency shell.

\*Only symmetrical overlap bring out the covalent bond formation, e.g.,

(vii) Between two orbitals of the same stability (i.e., having same energy) one more directionally concentrated would form a stronger bond. Dumb-bell shaped *p*-orbitals will form stronger bond as compared to spherically symmetrical s-orbital. It is formed by head on or axial overlap.

(viii) Two types of bonds are formed on account of overlapping. These are (a) Sigma ( $\sigma$ ) and (b) Pi ( $\pi$ ) bonds.

# 麗 (a) Sigma (σ) Bond

A bond formed between two atoms by the overlap of singly occupied orbitals along their axes (end to end overlap) is called **sigma** ( $\sigma$ ) **bond**. In such a bond formation, maximum overlap is possible between electron clouds and hence, it is a strong bond. Electron cloud of this bond is symmetrical about the line joining the two nuclei of the two atoms. Sigma bond can, thus, be defined as:

"Bond orbital which is symmetrical about the line joining the two nuclei is known as sigma bond." It is formed by head on or axial overlap.

Sigma bonds are formed by three types of overlapping:

(i) s-s overlapping (Formation of hydrogen molecule): Each hydrogen atom has one electron in 1s-orbital which is spherical. 1s-orbital of both the hydrogen atoms approach each other closely and when they reach a point of maximum attraction by the two nuclei, they overlap and form a sigma bond.

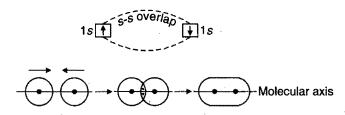

Fig. 2.7 Formation of H<sub>2</sub> molecule by s-s overlapping

The bond has two electrons which have opposite spins. The probability of finding these electrons is maximum in the region between the two nuclei on the molecular axis. The electron density of the bond is distributed symmetrically about the molecular axis.

- (ii) s-p overlapping (Formation of HF, H<sub>2</sub>O, NH<sub>3</sub> molecules) :
- (a) Formation of HF molecule: In the formation of HF molecule the 1s-orbital of hydrogen overlaps with the positial of fluorine containing unpaired electron.

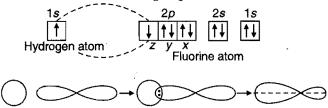

Fig. 2.8 Formation of HF molecule by s-p overlapping

**(b)** Formation of water molecule: Oxygen atom has the configuration of valency shell  $1s^2 2p_z^2 p_y^1 p_x^1$ , *i.e.*, it has two orbitals singly occupied. These two orbitals overlap with 1s-orbital of two hydrogen atoms forming sigma bonds.

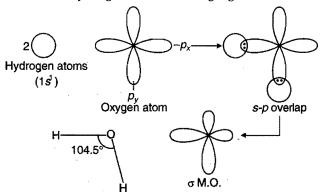

Fig. 2.9 Formation of water molecule by s-p overlapping

Since the two orbitals of oxygen are at right angle to each other an angle of 90° is expected between two sigma bonds but actual bond angle observed is 104.5°.

(c) Formation of ammonia molecule: Nitrogen atom has the configuration of valency shell  $2s^2 2p_x^1 2p_y^1 2p_z^1$ , *i.e.*, three singly occupied orbitals are present. These orbitals overlap with 1s-orbitals of three hydrogen atoms forming three sigma bonds.

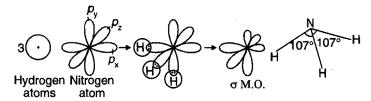

Fig. 2.10 Formation of NH3 molecule by s-p overlapping

Since the three orbitals of nitrogen are at right angle to each other, the expected angle between two sigma bonds should be 90 but actual bond angle observed is 107°.

(iii) p-p overlapping (Formation of fluorine molecule): This is illustrated by the formation of fluorine molecule. The electronic configuration of fluorine atom is  $1s^2 2s^2 2p_x^2 2p_y^2 2p_z^1$ , *i.e.*, one orbital is singly occupied. When p-orbitals of two fluorine atoms approach each other with their heads directly towards one another, they overlap and form a sigma bond.

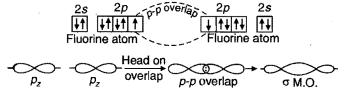

Fig. 2.11 Formation of F2 molecule by p-p overlapping

**Note :** Strongness of overlapping follows the following order : p-p > s-p > s-s

# 🗟 (b) Pi (π) Bond

 $\pi$ -bonds are formed by the sidewise or lateral overlapping of p-orbitals. The overlapping takes place at the side of two lobes and hence, the extent of overlapping is relatively smaller. Thus,  $\pi$ -bond is a weaker bond in comparison to sigma bond. The molecular orbital is oriented above and below the plane containing nuclear axis.

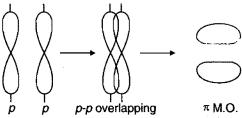

Fig. 2.12 Formation of  $\pi$ -bond

**Formation of oxygen molecule :** Oxygen atom has two p-orbitals singly occupied in the valency shell. When two oxygen atoms approach each other, one set of p-orbitals experiences head on overlap forming a sigma bond while other set of p-orbitals overlaps sidewise to form a  $\pi$ -bond. Thus, oxygen molecule has one  $\sigma$ - and one  $\pi$ -bond.

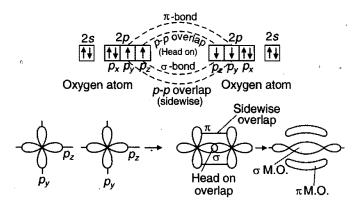

Fig. 2.13 Formation of O2 molecule

Similarly, the formation of nitrogen molecule can be explained. It has one sigma bond and two  $\pi$ -bonds.

## COMPARISON OF SIGMA ( $\sigma$ ) AND PI ( $\pi$ ) BOND

	Sigma bond	Pi bond
1.	•	
2.	It is a strong bond.	It is a weak bond.
3.	Electron cloud is symmetrical about the line joining the two nuclei.	Electron cloud is unsymmetrical.
4.	There can be free rotation of atoms around this bond.	Free rotation is not possible around this bond.
5.	These are less reactive.	These are more reactive.

6. The shape of the molecule is	These bonds do not affect the
determined by these bonds.	shape of the molecule.
<ol> <li>σ-electrons are referred as localized.</li> </ol>	$\pi$ -electrons are referred as mobile electrons.
8. σ-bond can have independent existence.	$\pi\text{-bond}$ always exists along with a $\sigma\text{-bond}.$

All single bonds are sigma bonds. A double bond consists of one sigma and one  $\pi$ -bond while a triple bond consists of one sigma and two  $\pi$ -bonds.

(i) **Bond energy** increases from a single bond to a triple bond.

Bond energy: Single bond < Double bond < Triple bond (ii) **Bond** strength increases from a single bond to a triple bond.

Bond strength: Single bond < Double bond < Triple bond (iii) **Bond length** of a multiple bond (double or triple) is always shorter than the corresponding single bond.

. Bond length: Single bond > Double bond > Triple bond

(iv) **Reactivity** of a multiple bond is always more than the single bond. This is due to the fact that  $\pi$ -electrons are mobile in nature.

Reactivity: Single bond < Double bond < Triple bond.

# 2.28 HYBRIDIZATION

The valence bond theory (overlapping concept) explains satisfactorily the formation of various molecules but it fails to account the geometry and shapes of various molecules. 31 does not give explanation why BeCl2 is linear, BF3 is plana: CH<sub>4</sub> is tetrahedral, NH<sub>3</sub> is pyramidal and water is V-shaped molecule. In order to explain these cases, the valence bond theory has been supplemented by the concept of hybridization. This is a hypothetical concept and has been introduced by Pauling and Slater. According to this concept any number of atomic orbitals of an atom which differ in energy slightly may mix with each other to form new orbitals called hybrid orbitals. The process of mixing or amalgamation of atomic orbitals of nearly same energy to produce a set of entirely new orbitals of equivalent energy is known as hybridization. The following are the rules of hybridization:

- (i) Only orbitals (atomic) of nearly same energy belonging to same atom or ion can take part in hybridization.
- (ii) Number of the hybrid orbitals formed is always equal to number of atomic orbitals which have taken part in the process of hybridization.
- (iii) Most of the hybrid orbitals are similar but they are not necessarily identical in shape. They may differ from one another in orientation in space.
- (iv) Actually the orbitals which undergo hybridization and not the electrons. For example, for orbitals of nitrogen atom  $(2s^2 2p_x^{1}2p_y^{1}2p_z^{1})$  belonging to valency shell when hybridize, form four hybrid orbitals,one of which has two electrons (as before) and other three have one electron each.

No. of atomic orbitals involved in hybridization	Type of hybridization	No. of hybrid orbitals	Shape of molecules		Bond angles	Examples	
. 2	sp (s + p)	2	Linear	**************************************	180°	BeCl <sub>2</sub> , BeF <sub>2</sub>	
3	$sp^2$ $(s+p+p)$	3	Plane triangular		120°	BF <sub>3</sub> , BCl <sub>3</sub>	
4	$sp^3$ $(s+p+p+p)$	4	Tetrahedral		109° 28′	CH <sub>4</sub> , CCl <sub>4</sub>	
4	$dsp^{2}$ one'd' $(d_{x}^{2}-y^{2})$ + one 's' + two 'p'	4	Square planar		90°	[Ni(CN) <sub>4</sub> ] <sup>2-</sup> , [PtCl <sub>4</sub> ] <sup>2-</sup>	
5	$dsp^3$ or $sp^3d$ one 's' + three 'p' + one $d(d_z^2)$	5	Trigonal bipyramid		120° and 90°	PCl <sub>5</sub>	
				*			
6	$d^{2}sp^{3}$ or $sp^{3}d^{2}$ one 's' + three 'p' + two 'd' $(d_{x}^{2}-y^{2},d_{z}^{2})$	6	Octahedral		90°	SF <sub>6</sub>	
7	$d^3sp^3$ or $sp^3d^3$ one 's' + three 'p' + three 'd' ( $d_{xy}$ , $d_{yz}$ , $d_{zx}$ )	. 7 I	Pentagonal bipyramid		72° and 90°	. IF <sub>7</sub>	

(v) The electron waves in hybrid orbitals repel each other and this tend to the farthest apart.

(vi) Hybrid orbitals form only sigma bonds. A hybrid bond is always stronger than a non-hybrid bond. Hybridization increases stability and decreases reactivity and energy of the molecule.

(vii) Depending on the number and nature of orbitals undergoing hybridization, various types of hybrid orbitals directing towards the corners of specified geometrical figures come into existence. The molecule has a **regular geometry** if all the hybrid orbitals after overlapping contain shared pair of electrons, *i.e.*, there are no orbitals containing lone pairs in the valency shell. If, however, the central atom is surrounded by one or more orbitals containing lone pairs of electrons in the valency shell, the geometry of the molecule is **distorted** to some extent. Thus, the presence of one or more orbitals with lone pairs affect the bond angle to some extent due to repulsion between lone pair (pairs) with bonded pair

(pairs). This type of observation has been made, for example, in the molecules of ammonia and water. The following table shows the type of hybridization and the geometry of the molecules containing only bond pairs of electrons.

# Some Typical Cases of Hybridization

(i)  $BeF_2$  molecule: Beryllium atom has the configuration  $1s^2$ ,  $2s^2$ . Since there are no unpaired electrons in the valency shell, it cannot form any covalent bond. Thus, 2s-orbital is first unpaired and an electron is shifted to 2p-orbital.

 Now, there is hybridization between one s- and one p-orbital. Two orbitals (hybrid) of same shape and energy come into existence. These overlap with p-orbital (singly occupied) each of the two fluorine atoms forming two sigma bonds. The molecule formed is linear with a bond angle  $180^{\circ}$ .

Fig. 2.14 Formation of BeF<sub>2</sub> molecule

(ii) BF<sub>3</sub> molecule: Boron atom has configuration  $1s^2$ ,  $2s^2$   $2p^1$ . In ground state, it has one unpaired orbital which can

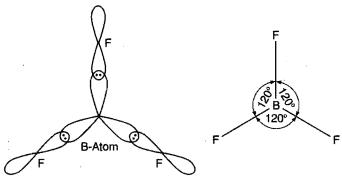

Fig. 2.15 Formation of BF3 molecule

only form only one covalent bond. To get trivalency, the 2s-orbital is unpaired and the electron is shifted to 2p-orbital. Now in excited state the three unpaired orbitals undergo hybridization giving rise to three hybrid orbitals which are 120° apart. The three hybrid orbitals overlap with three p-orbitals from three fluorine atoms forming three sigma bonds. The molecule formed is triangular and planar.

(iii)  $CH_4$  molecule: Carbon atom has configuration  $1s^2$ ,  $2s^2 2p_x^{-1}2p_y^{-1}$ . In ground state, it has two unpaired orbitals which can form only two covalent bonds. To get tetravalency, 2s-orbital is unpaired and the electron is shifted to 2p-orbital. Now in excited state the four unpaired orbitals undergo hybridization giving rise to four hybrid orbitals which are  $109^{\circ}28'$  apart. The four hybrid orbitals overlap with s-orbital of each of the four hydrogen atoms forming four sigma bonds. The molecule formed is tetrahedral.

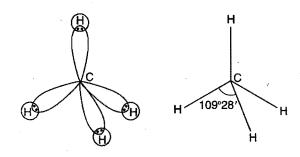

Fig. 2.16 Formation of CH<sub>4</sub> molecule

(iv) PCl<sub>5</sub> molecule: P-atom has configuration  $1s^2$ ,  $2s^22p^6$ ,  $3s^23p_x^1 3p_y^1 3p_z^1$ . In ground state, it can form three covalent bonds as three unpaired orbitals are present in the valency

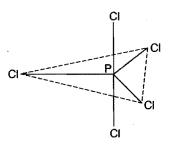

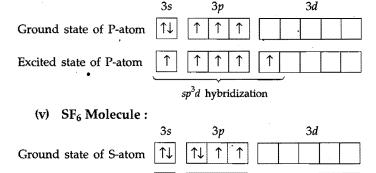

Fig. 2.17 Trigonal bipyramid

shell. To get pentavalency, 3s-orbital is unpaired and the electron is shifted to 3d-orbital. Now, in the excited state the five orbitals involving one s-, one d- and three p-orbitals undergo hybridization giving birth to five hybrid orbitals which overlap with five chlorine atoms forming five sigma bonds. Out of five  $\sigma$ -bonds, three bonds which are located at  $120^{\circ}$  angle are equitorial and the remaining two are axial. Axial bond length is greater.

3s- and paired 3*p*-orbital are unpaired and electrons are shifted to *d*-orbitals. After hybridization six hybrid orbitals directed towards the corners of a regular octahedron come

 $sp^3d^2$  hybridization

Excited state of S-atom

into existence which overlap with six fluorine atoms. The SF<sub>6</sub> molecule has octahedral structure.

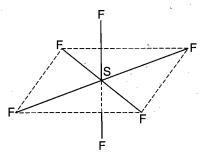

Fig. 2.18

# Geometry of Some Molecules Containing Lone Pairs of Electrons

(i) NH<sub>3</sub> molecu: Nitrogen atom undergoes  $sp^3$  hybridization forming four hybrid orbitals. Three of the hybrid orbitals contain one electron each while the fourth

2s

2p

Ammonia

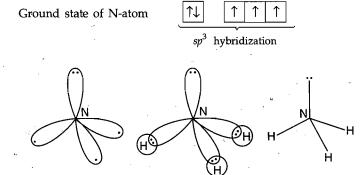

Fig. 2.19

Overlapping with

hydrogen atoms

Hybrid orbitals of N

one has a pair of electrons. Three hybrid orbitals having one electron each overlap with three hydrogen atoms forming three sigma bonds while the lone pair of fourth hybrid orbital remains unused.

The expected bond angle should be 109°28′ but the actual bond angle is 106°45′ because of the repulsion between lone pair and bonded pairs due to which contraction occurs. Thus, ammonia molecule is pyramidal in shape.

(ii) Water molecule: Oxygen atom undergoes  $sp^3$  hybridization forming four hybrid orbitals. Two of the hybrid orbitals contain one electron each while other two a pair of electrons each. The hybrid orbitals having one electron each overlap with hydrogen atoms forming two sigma bonds while the lone pairs of the other hybrid orbitals remain unused.

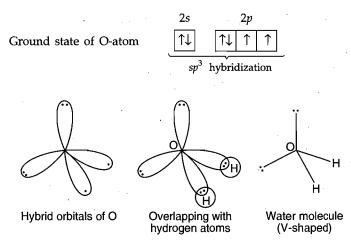

Fig. 2.20

The expected bond angle is 109°28′ but the actual bond angle is 104°35′. This is due to the presence of two lone pairs which repel each other and the bonded pairs more strongly and cause them to come closer and thereby reducing the bond angle from 109°28′ to 104°35′. Similarly, the geometry of PH<sub>3</sub>, PCl<sub>3</sub>, NF<sub>3</sub>, H<sub>2</sub>S, etc., can be explained. It is clear from the above two structures that **higher the number of lone pairs present on a central atom**, **the greater is the contraction caused in the bond angle**. The bond angle is also decreased as the size of the central atom increases. The bond angle in PH<sub>3</sub> is 93°20′.

# Geometry of Molecules Involving Sigma (σ) and Pi (π) Bonds

It is observed that it is not necessary to involve all the orbitals present in the valency shell of the atom in the process of hybridization. The following two examples illustrate this fact;

(i) Ethylene molecule ( $C_2H_4$ ): Ethylene molecule is formed as a result of  $sp^2$  hybridization of carbon. Each carbon atom in excited state undergo  $sp^2$  hybridization giving rise to three hybrid orbitals each. These hybrid orbitals lie in the xy plane while the fourth unhybridized orbital lies at right angle to the hybridized orbitals. In the formation of ethylene two hybrid orbitals, *i.e.*, one from each carbon atom form a sigma bond by head on overlap while the remaining overlap with hydrogen atoms. The unhybridized p-orbitals undergo sidewise overlap to form a  $\pi$ -bond.

Ground state of carbon atom 
$$\uparrow \downarrow$$
  $\uparrow \uparrow \uparrow$ 

Excited state of carbon atom  $\uparrow \downarrow$   $\uparrow \uparrow \uparrow \uparrow$ 
 $p^2$  hybridization

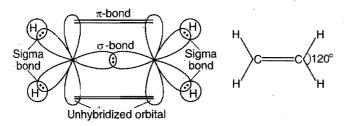

Fig. 2.21 Formation of Ethylene molecule

The molecule of ethylene is planar one:

(ii) Acetylene molecule ( $C_2H_2$ ): Acetylene molecule is formed as a result of sp hybridization of carbon. Each carbon atom in excited state undergoes sp hybridization giving rise to two hybrid orbitals each. Each carbon atom is left with two unhybridized p-orbitals.

Ground state of carbon atom 
$$\uparrow \downarrow \uparrow \uparrow \uparrow \uparrow$$

Excited state of carbon atom  $\uparrow \uparrow \uparrow \uparrow \uparrow \uparrow \uparrow$ 
 $p$  hybridization

The two hybrid orbitals of each carbon atom are used up in forming C—C and C—H sigma bonds. The unhybridized orbitals overlap sidewise to form two  $\pi$ -bonds.

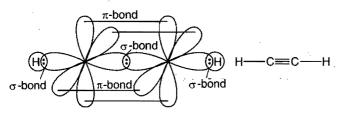

Fig. 2.22 Formation of acetylene molecule

Acetylene has linear structure.

# 2.29 RESONANCE

It is generally observed that a single valence bond structure of a molecule cannot correctly account for the properties of the molecule. In such cases, the concept of resonance is introduced. According to this concept if two or more alternate valence bond structures can be written for a molecule, the actual structure is said to be a resonance or mesomeric hybrid of all these alternate structures. For example, carbon dioxide molecule can be represented by the following three structures:

$$O = C = O \longleftrightarrow \overset{+}{O} = C - \overset{-}{O} \longleftrightarrow \overset{-}{O} - C = \overset{+}{O}$$

The calculated values of bond distances between carbon and oxygen in C=O and C=O are 1.22 Å and 1.10 Å, respectively but the observed bond distance between carbon

and oxygen in carbon dioxide is 1.15 Å. Thus, none of the above structures correctly explains the observed bond length. It is, thus, said that a hybrid form of these structures can provide the exact explanation. The various structures of which the molecule is a resonance hybrid are known as canonical forms or mesomeric forms. Actually resonance hybrid does not oscillate between the canonical forms of a mixture of these forms but it is a definite form and has a definite structure which cannot be written on paper.

# Rules for Selecting Canonical Forms or Mesomeric Forms :

- (i) The relative position of all the atoms in each of the canonical forms must be the same. They should differ only in the position of electrons.
- (ii) The number of unpaired and paired electrons in each of the canonical forms must be same.
- (iii) The contributing structures should not differ much in energy.
- (iv) The contributing structures should be such that negative charge resides on more electronegative and positive charge on the electropositive. Like charges should not reside on atoms close together in the canonical forms.

Formal charges on the atoms in the molecule help us in choosing the most appropriate resonance structure. For example, nitrous oxide molecule is represented by two resonance electron dot structures, one of which has a negative formal charge on the oxygen atom and the other of which has a negative charge on the terminal nitrogen atom.

$$:N \equiv \stackrel{\uparrow}{N} - \stackrel{\circ}{O} : \stackrel{-}{\longleftrightarrow} \stackrel{-}{N} = \stackrel{\uparrow}{N} = \stackrel{\circ}{O}$$

Since oxygen is a more electronegative element than nitrogen, the structure that places a negative formal charge on oxygen is probably lower in energy than the structure that has a negative formal charge on nitrogen.

Thus, the actual structure of  $N_2O$  is  $:N = \stackrel{+}{N} - \stackrel{\bullet}{O}:$ 

(v) As a result of resonance, the bond order changes in many molecules or ions.

Bond order = 
$$\frac{\text{Total number of bonds between two}}{\text{atoms in all the structures}}$$

$$e.g., (a) \longleftrightarrow B.O. = \frac{2+1}{2} = 1.5$$

B.O.=
$$\frac{2+1+1}{3}$$
= 1.33

# Resonance Energy

It has been observed that the molecule which shows resonance has greater heat of formation than the calculated heat of formation of any one of canonical forms. The difference is represented by  $\Delta E$  and its called resonance energy.

$$\Delta E = \begin{pmatrix} \text{Experimental value} \\ \text{of heat of formation} \end{pmatrix} \sim \begin{pmatrix} \text{Calculated value of heat} \\ \text{of formation of most} \\ \text{stable canonical form} \end{pmatrix}$$

On account of  $\Delta E$ , the hybrid form is more stable than any of the canonical forms.

Energy difference between most stable resonating structure and resonance nybrid structure is called resonance energy.

# **■ Some Examples Showing Resonance**

(i) Nitric oxide molecule: It is a resonance hybrid of following two structures:

$$\stackrel{\times}{\times}\stackrel{\times}{N}=0$$
:  $\stackrel{\times}{\longleftarrow}\stackrel{\times}{\times}\stackrel{\times}{N}^{-}=0$ :

(ii) Nitrogen dioxide molecule: It is a resonance hybrid of the following structures:

(iii) Carbonate ion: It is the resonance hybrid of the following forms:

(iv) Ozone:

$$\emptyset$$
  $\longleftrightarrow$   $\emptyset$ 

(v) SO<sub>2</sub> molecule:

(vi)  $NO_3^-$  ion:

$$\begin{bmatrix} 0 \\ 1 \\ N \\ 0 \end{bmatrix} \longleftrightarrow \begin{bmatrix} 0 \\ 1 \\ N \\ 0 \end{bmatrix} \longleftrightarrow \begin{bmatrix} 0 \\ \uparrow \\ N \\ 0 \end{bmatrix}$$

# 2.30 PREDICTION OF GEOMETRY (SHAPE) OF COVALENT MOLECULES

Geometry of a molecule or ion can be predicted if the state of hybridization at central atom is known. The type of hybridization can be known by the following methods:

First Method: The state of hybridization at central atom in a molecule can be known by counting the number of orbitals involved in co-axial overlappings and the number of orbitals with lone pair of electrons, *i.e.*, by counting the number of  $\sigma$ -bonds and the number of lone pair of electrons at central atom. Adding the two, if the total is 4, the hybridization is  $sp^3$ . If this total is 3, the hybridization is  $sp^2$  and if this total is 2, the hybridization is sp.

A few examples are being given below:

#### (a) Beryllium chloride (BeCl<sub>2</sub>)

No. of  $\sigma$ -bonds at Be atom = 2

No. of lone pair of electrons at Be atom = 0

$$Total = 2 + 0 = 2$$

Hybridization is *sp, i.e.*, BeCl<sub>2</sub> is linear and bond angle is 180°.

#### (b) Boron trichloride (BCl<sub>3</sub>)

No. of  $\sigma$ -bonds at B atom = 3

No. of lone pair of electrons at B atom = 0

Total = 3

Hybridization is  $sp^2$ , *i.e.*, BCl<sub>3</sub> is trigonal planar and bond angles are 120° each.

#### (c) Carbon tetrachloride (CCl<sub>4</sub>)

No. of  $\sigma$ -bonds at C atom = 4

No. of lone pair of electrons at C atom = 0

Total = 4

Hybridization is  $sp^3$ , i.e., CCl<sub>4</sub> is tetrahedral and bond angles are  $109^{\circ}28'$  each.

#### (d) Ammonia (NH<sub>3</sub>)

No. of  $\sigma_1$ bonds at N atom = 3

No. of lone pair of electrons at N atom = 1

Total = 3 + 1

= 4

Hybridization is  $sp^3$ .

Shape is trigonal pyramidal (not tetrahedral) and bond angles are not 109°28' but 106°45'.

#### (e) Water (H2O)

No. of  $\sigma$ -bonds at O atom = 2

No. of lone pair of electrons at O atom = 2

Total = 
$$2 + 2 = 4$$

Hybridization is  $sp^3$ .

Shape is angular or V-shape (not tetrahedral) and bond angle is not 109°28′ but 104°35′.

**Second Method:** Number of electron pairs in the valency shell of the central atom can be determined by applying the following formula:

#### For neutral molecules:

No. of electron pairs

= No. of atoms bonded to it  $+\frac{1}{2}$  [Group number

of central atom - Valency of the central atom]

No. of electron pairs at the central atom in CH<sub>4</sub>

$$=4+\frac{1}{2}[4-4]=4$$
 (sp<sup>3</sup> hybridization)

No. of electron pairs at the central atom in PCl<sub>5</sub>

$$= 5 + \frac{1}{2}[5 - 5] = 5$$
 (sp<sup>3</sup>d hybridization)

No. of electron pairs at the central atom in SF<sub>6</sub>

$$= 6 + \frac{1}{2}[6 - 6] = 6$$
 (sp<sup>3</sup>d<sup>2</sup> hybridization)

No. of electron pairs at the central atom in BF<sub>3</sub>

$$= 3 + \frac{1}{2}[3 - 3] = 3$$
 (sp<sup>2</sup> hybridization)

No. of electron pairs at the central atom in H<sub>2</sub>O

$$= 2 + \frac{1}{2}[6 - 2] = 4$$
 (sp<sup>3</sup> hybridization)

#### For ions:

No. of electron pairs = No. of atoms bonded to it

 $+\frac{1}{2}$ [Group number of central atom – Valency of the central atom  $\pm$  No. of electrons]

No. of electron pairs in NH<sub>4</sub><sup>+</sup>

$$=4+\frac{1}{2}[5-4-1]=4$$
 (sp<sup>3</sup> hybridization)

No. of electron pairs in  $SO_4^{2-}$ 

$$=4+\frac{1}{2}[6-8+2]=4$$
 (sp<sup>3</sup> hybridization)

No. of electron pairs in BF<sub>4</sub>

$$=4+\frac{1}{2}[3-4+1]=4$$
 (sp<sup>3</sup> hybridization)

No. of electron pairs	Geometrical figure	Examples	
2	Linear	BeCl <sub>2</sub> , CO <sub>2</sub> , ZnCl <sub>2</sub>	
3	Triangular Planar	BCl <sub>3</sub> , SO <sub>3</sub> , CO <sub>3</sub> <sup>2-</sup>	
4	Tetrahedral	CH <sub>4</sub> , H <sub>2</sub> O, NH <sub>3</sub>	
5	Trigonal bipyramid	PF <sub>5</sub> , ClF <sub>3</sub> , SF <sub>4</sub>	
6	Octahedral	SF <sub>6</sub> , IF <sub>5</sub> , SiF <sub>6</sub> <sup>2-</sup>	

**Third Method:** The number of orbitals involved in hybridization can be determined by the application of the following formula:

$$H = +\frac{1}{2}[V + M - C + A]$$

where H = number of orbitals involved in hybridization

V = valence electrons of central atom

M = number of monovalent atoms linked with central atom

C = charge on the cation

A = charge on the anion

From the value of H, the type of hybridization can be predicted.

Value of H	2	3	4	5	6	7 .	
Hybridization	sp	$sp^2$	$sp^3$	$sp^3d$	$sp^3d^2$	$sp^3d^3$	

### Type 1. Neutral molecules:

(i) 
$$CO_2$$
:  $V = 4$ ,  $M = 0$ ,  $C = 0$ ,  $A = 0$   
 $H = \frac{1}{2} [4 + 0 - 0 + 0] = 2$ ,  $sp$  hybridization

(ii) 
$$SO_2$$
 or  $V = 6$ ,  $M = 0$ ,  $C = 0$ ,  $A = 0$ 

$$SO_3$$
:  $H = \frac{1}{2} [6 + 0 - 0 + 0] = 3$ ,  $sp^2$  hybridization

(iii) 
$$BCl_3$$
:  $V = 3$ ,  $M = 3$ ,  $C = 0$ ,  $A = 0$ 

$$H = \frac{1}{2} [3 + 3 - 0 + 0] = 3$$
,  $sp^2$  hybridization

(iv) 
$$SiCl_4$$
:  $V = 4$ ,  $M = 4$ ,  $C = 0$ ,  $A = 0$ 

$$H = \frac{1}{2} [4 + 4 - 0 + 0] = 4$$
,  $sp^3$  hybridization

(v) 
$$ClF_3$$
:  $V = 7$ ,  $M = 3$ ,  $C = 0$ ,  $A = 0$ 

$$H = \frac{1}{2} [7 + 3 - 0 + 0] = 5, sp^3 d$$
 hybridization

(vi) 
$$XeF_4$$
:  $V = 8$ ,  $M = 4$ ,  $C = 0$ ,  $A = 0$ 

$$H = \frac{1}{2} [8 + 4 - 0 + 0] = 6, sp^3 d^2$$
 hybridization

#### Type 2. When the species is a cation:

(i) 
$$NH_4^+$$
:  $V = 5$ ,  $M = 4$ ,  $C = 1$ ,  $A = 0$   
 $H = \frac{1}{2} [5 + 4 - 1 + 0]$   
 $= 4$ ,  $sp^3$  hybridization

(ii) 
$$CH_3^+$$
:  $V = 4$ ,  $M = 3$ ,  $C = 1$ ,  $A = 0$   
 $H = \frac{1}{2} [4 + 3 - 1 + 0]$   
 $= 3$ ,  $sp^2$  hybridization

(iii) NO<sub>2</sub><sup>+</sup>: V = 5, M = 0, C = 1, A = 0  
H = 
$$\frac{1}{2}$$
 [5 + 0 - 1 + 0]  
= 2, sp hybridization

### Type 3. When the species is an anion:

(i) 
$$CO_3^{2-}$$
:  $V = 4$ ,  $M = 0$ ,  $C = 0$ ,  $A = 2$   
 $H = \frac{1}{2} [4 + 0 - 0 + 2]$   
 $= 3$ ,  $sp^2$  hybridization

(ii) 
$$SO_4^{2-}$$
:  $V = 6$ ,  $M = 0$ ,  $C = 0$ ,  $A = 2$   
 $H = \frac{1}{2}[6 + 0 - 0 + 2] = 4$ ,  $sp^3$  hybridization  
(iii)  $ICl_4^-$ :  $V = 7$ ,  $M = 4$ ,  $C = 0$ ,  $A = 1$   
 $H = \frac{1}{2}[7 + 4 - 0 + 1] = 6$ ,  $sp^3d^2$  hybridization

# 2.31 VALENCE SHELL ELECTRON PAIR REPULSION (VSEPR) THEORY

Lewis-Langmuir concept of covalent bonding is unable to explain the shapes of the covalent molecules. In case of covalent molecules having three or more atoms, one of the atoms acts as a central atom and rest of the atoms are linked to it in definite directions in space. This definite arrangement of the bonded atoms with the central atom in a molecule is known as shape or geometry of the molecule.

The first simple theory that was put forward to predict the geometry or shape of a covalent molecule is known as Valence Shell Electron Pair Repulsion Theory (or VSEPR theory). This theory was first proposed by Sidgwick and Powell in 1940 and was further developed by Nyholm and Gillespie in 1957.

The theory, known as VSEPR theory, is primarily based on the fact that in a polyatomic molecule, the direction of bond around the central atom depends upon the total number of electron pairs (bonding as well as non-bonding) in its valence shell. These electron pairs place themselves as far apart as possible in space in order to have minimum forces of repulsion between them. The minimum repulsions correspond to the state of minimum energy and maximum stability of the molecule.

The main postulates of VSEPR theory are as follows:

- (i) The shape of a molecule depends upon the number of valence shell electron pairs (bonded or non-bonded) around the central atom.
- (ii) Pairs of electrons in the valence shell repel one another since their electron clouds are negatively charged.
- (iii) The positions of the electron pairs in space around central atom are such that minimise repulsion and thus maximise distance between them.
- (iv) The magnitudes of the different types of electronic repulsions follows the order given below:

These repulsive forces alter the bond angles of the molecule or ion.

(v) The electronic repulsion between two pairs of electrons will be minimum if they are as far apart as possible. On this basis, the following geometrical arrangements are most suited.

No. of 2 3 4 5 6 electron pairs 
Geometrical Linear Triangular Tetra- Trigonal Octafigure 
Examples BeCl<sub>2</sub>, BCl<sub>3</sub>, SO<sub>3</sub> CFl<sub>4</sub>, H<sub>2</sub>O PF<sub>5</sub>, CIF<sub>3</sub>, SF<sub>6</sub>, IF<sub>5</sub> CO<sub>2</sub>, ZnCl<sub>2</sub> 
$$CO_3^{2-}$$
 NH<sub>3</sub> SF<sub>4</sub> SiF $_6^{2-}$ 

(vi) If the central atom is linked to similar atoms and is surrounded by bond pairs of electrons, the repulsions between them are similar. As a result the shape of the molecule is **symmetrical** and the molecule is said to have a **regular geometry**. On the other hand, the molecules in which the repulsive interactions between the electron pairs around the central atom are unequal have **irregular** or **distorted geometry**. In fact, the presence of lone pairs in addition to bond pairs in the molecule causes distortion in the geometry of the molecule. For example, in the NH<sub>3</sub> and H<sub>2</sub>O molecules, the bond angles are not 109°28' but 106.5° and 104.5° respectively due to presence of one lone pair in NH<sub>3</sub> and two lone pairs in H<sub>2</sub>O.

[In the VSEPR notation used to describe molecular geometries, the central atom is denoted as A, terminal atoms as X and lone pairs as E.  $AX_2E_2$  describes a structure with two terminal atoms and two lone pairs around a central atom, for example water molecule. Similarly,  $AX_3E_2$  describes a structure with three terminal atoms and two lone pairs around a central atom. For example CIF<sub>3</sub> molecule.]

(vii) A multiple bond is treated as if it is a single electron pair and two or three electron pairs of a multiple bond are treated as a single super pair.

(viii) Where two or more resonance structures can represent a molecule, the VSEPR model is applicable to any such structure.

## A Strategy for Applying VSEPR Method

To predict the shape of a molecule or polyatomic ion, the following four steps can be followed:

**Step 1:** Draw a Lewis structure of the molecule or polyatomic ion. The structure must be plausible but it does not need to be the best one.

**Step 2:** Determine the number of electron groups around the central atom (bonding and non-bonding both). A double and a triple bond each is counted as one electron group.

**Step 3:** Identify the electron group geometry. This may be linear, trigonal planar, tetrahedral, trigonal bipyramidal or octahedral corresponding to two, three, four, five and six electron groups respectively.

**Step 4:** Identify the molecular geometry. This is based on the positions around the central atom occupied by other atoms (not by lone pairs).

Molecular Geometry Around Atoms with 2, 3, 4, 5 and 6 charge clouds (Total number electron pairs-bonding and non-bonding)

Number of Bonds (a)	Number of Lone Pairs (b)	Total Number of Charge Clouds (a + b)	notation	Molecular Geometry	Example

### illustration of the Theory by Considering a Few Examples

#### (A) Molecules containing bond pairs only

(i) Shape of BeF<sub>2</sub> molecule: Be-atom is surrounded by two bond pairs of electrons. These should be localised in such a way that there is minimum repulsion between them, *i.e.*, bond angle should be 180°, hence BeF<sub>2</sub> molecule is **Linear**.

Molecules such as BeCl<sub>2</sub>, ZnCl<sub>2</sub>, HgCl<sub>2</sub>, etc., have a linear shape.

(ii) Shape of  $BF_3$  molecule: The Lewis structure of  $BF_3$  is:

$$F \overset{\bullet}{\underset{\bullet}{\times}} B \overset{\bullet}{\underset{\bullet}{\times}} F$$

B-atom is surrounded by three bond pairs. According to VSEPR theory they must be situated at an angle of 120° as they will experience minimum repulsion, *i.e.*, shape of BF<sub>3</sub> is **triangular planar**.

Molecules such as BCl<sub>3</sub>, AlCl<sub>3</sub>, etc., have a triangular planar shape.

(iii) Shape of  $CH_4$  molecule: The Lewis structure of  $CH_4$  is:

C-atom is surrounded by four bond pairs. These four bond pairs adopt tetrahedral structure as to remain as far apart as possible in order to have minimum repulsion. The bond angle is  $109^{\circ}28'$  (or approximately  $109.5^{\circ}$ ). Species such as  $SiF_4$ ,  $CCl_4$ ,  $SiH_4$ ,  $NH_4^{\dagger}$ , etc., have tetrahedral structure.

(iv) Shape of PCl<sub>5</sub> molecule: The Lewis structure of PCl<sub>5</sub> is:

P-atom is surrounded by five bond pairs. To have minimum energy, the bond pairs of electrons should be as far apart as possible from each other. This is possible if the molecule acquires a **trigonal bipyramidal** shape. In this geometry all the bond angles are not equal. The axial bonds are of 90° and the bond angles in the triangle plane are of 120°. Two axial P—Cl bonds are longer as compared to three equatorial bonds. This is due to the fact that axial bond experiences greater repulsion from other bonds.

Molecules such as PF<sub>5</sub>, SbCl<sub>5</sub>, etc., have same shape.

(v) Shape of  $SF_6$  molecule: The Lewis structure of  $SF_6$  is:

S-atom is surrounded by six bond pairs. According to VSEPR theory these bond pairs adopt an **octahedral** geometry. In this geometry, all the bond angles are  $90^{\circ}$  each. The molecule is symmetrical and stable, *i.e.*, less reactive. TeF<sub>6</sub> molecule is also expected to have the same shape.

#### (B) Molecules containing lone pairs and bond pairs

(1) Molecules containing two bonding electron pairs and one lone pair  $(AX_2E)$ : The molecule contains three electron pairs. Thus, it should have a trigonal planar geometry. Due to the presence of one lone pair, the geometry gets distorted. For example,  $SO_2$  has a V-shaped geometry. The bond angle is reduced to 119.5°.

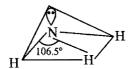

Shape of SO<sub>2</sub> molecule

- (2) Molecule containing four electron pairs
- (a) Molecules containing three bonding electron pairs and one lone pair  $(AX_3E)$

Shape of  $NH_3$  molecule: The Lewis structure of  $NH_3$  is:

N-atom is surrounded by four electron pairs (three bonded and one lone pair). These four pairs adopt tetrahedral geometry. Due to presence of lone pair, NH<sub>3</sub> has a distorted tetrahedral geometry. The bond angle is not 109°28' but it is 106.5°. The actual shape of ammonia molecule is **pyramidal**.

Shape of NH<sub>3</sub> molecule

Molecules such as  $PCl_3$ ,  $NF_3$ ,  $H_3O^+$ , etc., have same shape. (b) Molecules containing two bonding electron pairs and two lone pairs  $(AX_2E_2)$ 

**Shape of water molecule:** The Lewis structure of water is:

O-atom is surrounded by four electron pairs (two bonded and two lone pairs). These four electron pairs adopt

tetrahedral arrangement. The presence of two lone pairs brings distortion in the geometry of the molecule. The lone pairs repel the bond pairs more effectively resulting in the decrease of bond angle from 109°28' to 104.5°. The actual shape of the water molecule is V-shape.

Molecules/ions such as  $F_2O$ ,  $NH_2^-$ ,  $SCl_2$ ,  $PbCl_2$ , etc., have shape similar to water molecule.

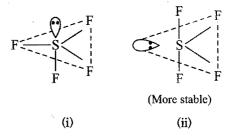

Shape of H<sub>2</sub>O molecule

(3) Molecules containing five electron pairs

(a) Molecules containing four bonding electron pairs and one lone pair  $(AX_4E)$ 

The example is  $SF_4$  molecule. The molecule has five electron pairs and should have trigonal bipyramidal geometry in which one position is occupied by a lone pair.

Therefore, SF<sub>4</sub> molecule can have either of the following two structures.

In structure (i) the lone pair is on axial position while in structure (ii) the lone pair is on equatorial position. The structure (ii) will therefore, experience lesser repulsions than structure (i). Thus the structure (ii) which is described as distorted tetrahedron or a folded square or see-saw will be a more stable correct structure of SF<sub>4</sub>. The bond angles are 89° and 117° instead of 90° and 120° respectively.

## -(b) Molecules containing three bonding electron pairs and two lone pairs $(AX_3E_2)$

The example is ClF<sub>3</sub>. The molecule has five electron pairs and it should have a trigonal bipyramidal geometry in which two positions are occupied by lone pairs. Therefore, the molecule, ClF<sub>3</sub>, can have either of the following three structures.

Structure (i) is most stable as it will experience lesser repulsions in comparison to structures (ii) and (iii). Thus, the molecule has a T-shaped structure and bond angle is 87.6°.

# (c) Molecules containing two bonding electron pairs and three lone pairs $(AX_2E_3)$

The example is XeF<sub>2</sub>. It has five electron pairs and it should have a trigonal bipyramidal geometry in which three positions are occupied by lone pairs. If the three lone pairs are present on the corners of an equatorial triangle, the net repulsion will be zero.

Thus, the most correct and stable shape will be linear.

Linear shape

#### (4) Molecules containing six electron pairs

# (a) Molecules containing five bonding electron pairs and one lone pair $(AX_5E)$

The example is BrF<sub>5</sub>. It has six electron pairs and it should have an octahedral geometry in which one position is occupied by a lone pair. Since all the six positions in octahedron are equivalent, the lone pair can be present on any one position. Thus, the molecule has a square pyramidal geometry.

# (b) Molecules containing four bonding electron pairs and two lone pairs $(AX_4E_2)$

The example is XeF<sub>4</sub>. It has six electron pairs and should have octahedral geometry in which two positions are occupied by lone pairs.

The shape of the molecule is square planar.

## 2.32 BOND CHARACTERISTICS

Covalent bonds are characterised by the following four parameters:

- (1) Bond length
- (2) Bond energy
- (3) Bond angle
- (4) Bond order

#### (1) Bond Length:

The distance between the nuclei of two atoms bonded together is termed bond length or bond distance. It is expressed in angstrom (Å) or picometre (pm) units:

$$[1 \text{ Å} = 10^{-8} \text{ cm}; 1 \text{ pm} = 10^{-12} \text{ m}]$$

#### **BOND LENGTHS**

Bond	Bond length (Å)	Bond	Bond length (Å)
НН	0.74	H—F	0.92
(in H <sub>2</sub> )	-	(in HF)	·
Cl—Cl	1.99	H—Cl	1.27
(in Cl <sub>2</sub> )		(in HCl)	
Br-Br	2.28	HBr	1.41
(in Br <sub>2</sub> )		(in HBr)	
II	2.67	H—I	1.61
$(in, I_2)$		(in HI)

Bond lengths are measured spectroscopically or by X-ray diffraction of solids and electron diffraction of gases. In ionic compounds, bond length is obtained by adding up of the ionic radii of two bonded ions.

Bond length in ionic compound =  $r_c^+ + r_a^-$ 

Similarly, in a covalent compound, bond length is obtained by adding up the covalent (atomic) radii of two bonded atoms.

Bond length in covalent compound  $(AB) = r_A + r_B$ 

The factors such as resonance, electronegativity, hybridization, steric effects, etc., which affect the radii of atoms, also apply to bond lengths, *i.e.*, the values of bond lengths do not hold good for all the compounds. Bond lengths of some common bonds are tabulated in the table given above.

When there is large difference in electronegativity of the two atoms, the bond length is generally less than the sum of the covalent radii of the two atoms.

#### Important features:

(i) The bond length of the homonuclear diatomic molecules are twice the covalent radii. Bond length increases with the increase in the size of atoms.

(ii) The lengths of double bonds are less than the lengths of single bonds between the same two atoms and triple bonds are even shorter than double bonds.

Single bond > Double bond > Triple bond

(iii) Bond length decreases with increase in s-character since s-orbital is smaller than a p-orbital.

$$sp^3$$
 C—H = 1.112 Å;  $sp^2$  C—H = 1.103 Å; (25% s-character as in alkanes) as in alkenes)  $sp$  C—H = 1.08 Å (50% s-character as in alkynes)

- (iv) Bond length of polar bond is smaller than the theoretical non-polar bond length.
- (v) Bond length is affected by resonance and hyperconjugation.

#### (2) Bond Energy or Bond Strength:

Bond energy or bond strength is defined as the amount of energy required to break a bond in a molecule. Each bond has a characteristic value of this energy and is measure of the strength of the bond. It is generally observed that shorter the bond length, greater is the bond strength or bond energy of the bond.

$$H \rightarrow H(g) \longrightarrow 2H(g)$$
  $\Delta H = 436 \text{ kJ mol}^{-1}$  (Bond length = 0.74 Å)  
 $Cl \rightarrow 2Cl(g)$   $\Delta H = 242 \text{ kJ mol}^{-1}$  (Bond length = 1.99 Å)  
 $H \rightarrow Cl(g) \longrightarrow H(g) + Cl(g)$   $\Delta H = 431 \text{ kJ mol}^{-1}$  (Bond length = 1.27 Å)

Consider the dissociation of water molecule which consists of two O—H bonds.

$$H-O-H(g) \longrightarrow 2H(g) + O(g);$$
  $\Delta H = 926 \text{ kJ mol}^{-1}$ 

The average bond energy of O—H bond =  $\frac{926}{2}$  = 463 kJ

Similarly, the average bond energy of C—H bond in  $CH_4$  is equal to one-fourth of the energy of dissociation of  $CH_4$  into (C+4H). However, the bond energy of each C—H bond in  $CH_4$  is different.

$$CH_4(g) \longrightarrow CH_3(g) + H(g);$$
  $\Delta H = 426 \text{ kJ mol}^{-1}$   
 $CH_3(g) \longrightarrow CH_2(g) + H(g);$   $\Delta H = 439 \text{ kJ mol}^{-1}$   
 $CH_2(g) \longrightarrow CH(g) + H(g);$   $\Delta H = 451 \text{ kJ mol}^{-1}$   
 $CH(g) \longrightarrow C(g) + H(g);$   $\Delta H = 347 \text{ kJ mol}^{-1}$   
 $CH_4(g) \longrightarrow C(g) + 4H;$   $\Delta H = 1663 \text{ kJ mol}^{-1}$ 

Hence, average bond energy C—H =  $\frac{1663}{4}$  = 416 kJ mol<sup>-1</sup>

Thus, the bond energy of C—H bond depends on the order in which the particular hydrogen atom is lost from the molecule. A similar situation exists for all molecules with more than two atoms. The strengths of the bonds depend on the order in which they are broken. Average bond energies of some common bonds are listed below:

BOND ENERGIES IN kJ mol<sup>-1</sup>

	. *		
Bond	Bond energy	Bond	Bond energy
Н—Н	436	Cl—Cl	242
O=O	497	Br—Br	193
N≡N	945	I—I ·	151
F—F	158	$H$ $\longrightarrow$ $F$	563
H—Cl	431	N—H	389
:		(in NH <sub>3</sub> )	·.
H—Br	366	О—Н	464
		(in water)	
H—I	299	C—C	346
C—H	416	C = C	598
(in methane)		(in C <sub>2</sub> H <sub>4</sub> )	

#### Important features:

- (i) The magnitude of the bond energy depends on the type of bonding. Most of the covalent bonds have energy between 50 to 100 kcal  $\text{mol}^{-1}$  (200–400 kJ  $\text{mol}^{-1}$ ). Strength of sigma bond is more than that of a  $\pi$ -bond.
- (ii) A double bond in a diatomic molecules has a higher bond energy than a single bond and a triple bond has a higher bond energy than a double bond between the same atoms.

$$C \equiv C > C = C > C - C$$

- (iii) The magnitude of the bond energy depends on the size of the atoms forming the bond, *i.e.*, bond length. Shorter the bond length, higher is the bond energy.
- (iv) Resonance in the molecule affects the bond energy.
- (v) The bond energy decreases with increase in number of lone pairs on the bonded atom. This is due to electrostatic repulsion of lone pairs of electrons on the two bonded atoms.
- (vi) Homolytic and heterolytic fission involve different amounts of energies. Generally the values are low for homolytic fission of the bond in comparison to heterolytic fission.
- (vii) Bond energy decreases down the group in case of similar molecules.
- (viii) Bond energy increases in the following order:

$$s 
C—C > N—N > O—O
346 163 146.4 kJ mol<sup>-1</sup>
(No lone pair) (One lone pair) (Two lone pairs)$$

(ix) Bond energy of covalent molecule can be calculated using Pauling's formula.

$$E_{A-B} = 1/2 [E_{A-A} + E_{B-B}] + 23 (x_A - x_B)^2$$
 where  $E_{A-B}$ ,  $E_{A-A}$  and  $E_{B-B}$  are the bond energies of the molecules  $A-B$ ,  $A_2$  and  $B_2$  respectively and  $xA$  and  $xB$  are the electronegativity of  $A$  and  $B$ .  $A$  more accurate

value is obtained when geometric mean  $\sqrt{E_{A-A}\times E_{B-B}}$  is used instead of arithmetic mean,  $\frac{E_{A-A}+E_{B-B}}{2}$ .

## ■ (3) Bond Angles

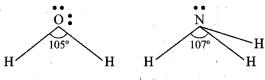

Angle between two adjacent bonds at an atom in a molecule made up of three or more atoms is known as the bond angle. Bond angles mainly depend on the following three factors:

(i) **Hybridization**: Bond angle depends on the state of hybridization of the central atom.

Hybridization	$sp^3$	$sp^2$	sp
Bond angle	109°28′	120°	180°
Example	$CH_4$	$BCl_3$	BeCl <sub>2</sub>

It is observed that as s-character increases in the hybrid bond, the bond angle increases.

(ii) Lone pair repulsion: Bond angle is affected by the presence of lone pair of electrons at the central atom. A lone pair of electrons at the central atom always tries to repel the shared pair (bonded pair) of electrons. Due to this, the bonds are displaced slightly inside resulting in a decrease of bond angle. The bond angle in NH<sub>3</sub> is  $107^{\circ}$  and bond angle in H<sub>2</sub>O is  $105^{\circ}$  inspite of the fact that N-atom and O-atom undergo  $sp^3$  hybridization.

Water molecule

Ammonia molecule

(iii) **Electronegativity**: If the electronegativity of the central atom decreases, bond angle decreases.

In case the central atom remains the same, bond angle increases with decrease in the electronegativity of the surrounding atoms.

#### (4) Bond order

Bond order is defined as the number of bonds or number of shared electron pairs between two atoms in a molecule.

Н—Н	or	H : H	Bond order = $1$
O=O	or	0::0	Bond order $= 2$
N≡N	or	N : N	Bond order $= 3$
C≡O	or	C : O	Bond order $= 3$

Isoelectronic molecules or ions have same bond order.

For example,  $F_2$  and  $O_2^{2-}$  (18 electrons) have bond order 1.  $N_2$ , CO and  $NO^+$  (14 electrons) have bond order 3.

It is observed that with increase in bond order, bond enthalpy increases while bond length decreases.

## 2.33 ODD ELECTRON BONDS

In 1916 Luder postulated that there are number of stable molecules in which double bonds are formed by sharing of an odd number of electrons, i.e., one, three, five, etc., between

the two bonded atoms. The bonds of this type are called odd electron bonds.

An example of one electron bond is found in the hydrogen molecule ion,  $H_2^+$ . It has a bond energy of 61 kcal/mol. The ion is less stable than  $H_2$  molecule as a bond length is longer than two electrons bond in  $H_2$ . The excited state of alkali metal molecules involve odd electron bonds. Thus,  $\text{Li}_2^+$ ,  $\text{K}_2^+$ ,  $\text{Na}_2^+$  are all bound by one electron.

 $\text{He}_2^+$  ion,  $\text{O}_2$  molecule, nitric oxide molecule, nitrogen dioxide molecule, etc., are the examples of three electrons bonds.  $\text{He}_2^+$ ion is a resonance hybrid of following two forms:

$$He_{\times}^{\times} \cdot He^{+} \longleftrightarrow He^{+} \cdot_{\times}^{\times} He$$

The normal valence bond structure of oxygen molecule,  $\overset{\star\star}{\cdot \circ} = \overset{\star\times}{O_{\times}}^{\times}$ , fails to account for the paramagnetic nature of oxygen. Thus, structure involving three electrons bond has been suggested by Pauling. The following structure:

explains the paramagnetic nature and high dissociation energy of oxygen molecule.

#### **№** Properties of Odd Electron Bonds

- (i) The odd electron bonds are generally established either between two like atoms or between different atoms which have not more than 0.5 difference in their electronegativities.
- (ii) Odd electron bonds are approximately half as strong as a normal covalent bond.
- (iii) Molecules containing odd electrons are extremely reactive and have the tendency to dimerise.
- (iv) Bond length of one electron bond is greater than that of a normal covalent bond. Whereas the bond length of a three electron bond is intermediate between those of a double and a triple bond.
- (v) One electron bond is a resonance hybrid of the following two structures:

$$A \bullet B \longleftrightarrow A \bullet B$$

Similarly, a three electron bond is a resonance hybrid of the following two structures:

$$A \bullet B \longleftrightarrow A \bullet B$$

## 2.34 MOLECULAR ORBITAL THEORY

The valence bond theory is based on the assumption that the formation of a molecule involves an interaction between the electron waves of only those atomic orbitals of the participating atoms which are half filled. These atomic orbitals mix with one another to form a new orbital of greater stability while all other orbitals on the atoms remain undisturbed or maintain their individual identity. But this cannot be correct because the nucleus of one approaching atom is bound to affect the electron waves of nearly all the orbitals of the other atom. Besides this, the valence bond theory fails to explain the formation of coordinate bond, the

paramagnetic character of  $O_2$  molecule and the formation of odd electron molecules or ions such as  $H_2^+$  ion where no pairing of electron occurs.

Molecular orbital theory of chemical bonding is more rational and more useful in comparison to valence bond theory. This theory was put forward by Hund and Mullikan. According to this theory, all the atomic orbitals of the atoms participating in molecule formation get disturbed when the concerned nuclei approach nearer. They all get mixed up to give rise to an equivalent number of new orbitals that belong to the molecule now. These are called molecular orbitals. The electrons belonging originally to the participating atoms are now considered to be moving along the molecular orbitals under the influence of all the nuclei. Thus, molecular orbitals are polycentric. Molecular orbital is defined as the region in space comprising the nuclei of the combining atoms around which there is maximum probability of finding the electron density.

Molecular orbitals are of varying energies and are arranged in the order of increasing energy levels as in the case of atomic orbitals. The filling of electrons in the molecular orbitals follows, aufbau principle and Hund's rule.

## Linear Combination of Atomic Orbitals (LCAO)

Molecular orbitals of a molecule are obtained by the linear combination of atomic orbitals of the bonded atoms. The electron waves that describe the atomic orbitals have positive and negative phase or amplitude just as there are positive (upward) and negative (downward) amplitudes associated with standing wave. When waves are combined, they may interact either constructively or destructively. If the two identical waves are added, they combine constructively to produce the wave with double the amplitude and same wavelength. Conversely, if they are subtracted, they combine destructively to produce the wave with zero amplitude. This has been shown in Fig. 2.23.

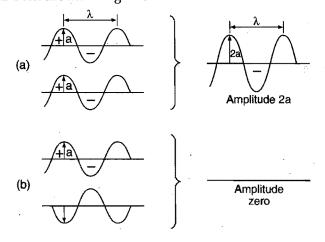

Fig. 2.23

Likewise when two atomic orbitals overlap they can be in phase (added) or out of phase (subtracted). If they overlap in phase, constructive interaction occurs in the region between two nuclei and a **bonding orbital** is produced. When they overlap out of phase, destructive interference reduces the probability of finding an electron in the region between the nuclei and **antibonding orbital** is produced.

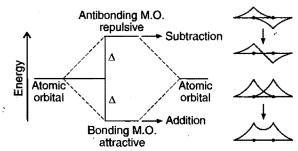

Fig. 2.24 Formation of bonding and antibonding molecular orbitals

This can be shown mathematically also. Suppose  $\psi_A$  and  $\psi_B$  represent the amplitude (or also called wave functions) of the electron waves of the atomic orbitals of the two atoms A and B respectively. When these waves overlap, two cases may arise:

Case I. When the two waves are in phase, *i.e.*, constructive interference occurs, the waves are added so that the amplitude of the new wave is

$$\phi = \psi_A + \psi_B$$

Case II. When the two waves are out of phase, *i.e.*, destructive interference occurs, the waves are subtracted from each other so that the amplitude of the new wave is

$$\phi' = \psi_A - \psi_B$$

The probable electron density is given by the square of the amplitude, therefore we have

$$\phi^{2} = (\psi_{A} + \psi_{B})^{2} = \psi_{A}^{2} + \psi_{B}^{2} + 2\psi_{A}\psi_{B}$$
and
$$\phi'^{2} = (\psi_{A} - \psi_{B})^{2} = \psi_{A}^{2} + \psi_{B}^{2} - 2\psi_{A}\psi_{B}$$
i.e.,
$$\phi^{2} > \psi_{A}^{2} + \psi_{B}^{2}$$
whereas  $\phi'^{2} < \psi_{A}^{2} + \psi_{B}^{2}$ 

The above relation shows that the probability of finding the electrons in the bonding molecular orbital increases whereas it decreases in the antibonding molecular orbital. In other words, it can be said that electron density is high between the nuclei of two bonded atoms due to increased attraction in case of bonding molecular orbital whereas most of the electron density is located away from the space between the nuclei due to repulsion in case of antibonding molecular orbital. In fact, there is a nodal plane between the two nuclei of antibonding molecular orbital where electron density is zero.

Just as letters s, p, d, etc., are used to denote the atomic orbitals, similarly Greek symbols,  $\sigma$ ,  $\pi$ ,  $\delta$ , etc., are used to denote the bonding molecular orbitals and asterisk symbols

 $\sigma^*$ ,  $\pi^*$ ,  $\delta^*$ , etc., are used to represent antibonding molecular orbitals.

Note: Crests of the electron waves are given '+' sign and troughs a '-' sign. Thus, bonding molecular orbital is formed by combination of '+' with '+' and '-' with '-' part of the electron waves whereas antibonding molecular orbital is formed by combination of '+' with '-' part of the electron waves.

The energy of the bonding molecular orbital is always lower than the energy of the atomic orbitals of the combining atoms whereas the energy of the antibonding molecular orbital is higher than the energy of the combining atomic orbitals as bonding molecular orbital is more stable and antibonding molecular orbital is less stable. However, it should be noted that compared with the energy of the combining atomic orbitals, the energy of the antibonding molecular orbital is raised by an amount greater than the amount by which the energy of the bonding orbital is lowered but the sum of the energies of bonding molecular orbital and antibonding molecular orbital is equal to the sum of energies of the combining atomic orbitals. The lowering in energy ( $\Delta$ ) of the bonding molecular orbital than the combining atomic orbital is called stabilization energy while increase in energy ( $\Delta'$ ) of the antibonding molecular orbital is called destabilizing energy.

#### Distinction between Atomic and Molecular Orbitals

	Atomic orbital	Molecular orbital
1.	<i>i.e.</i> , electron cloud extends around the nucleus of a single	Molecular orbital is polycentric, i.e., the electron cloud extends around all the nuclei of bonded atoms in
•	atom.	the molecule.
2.	It is less stable.	It is more stable.
3.	It has simple shape.	It has complex shape.
4.	Atomic orbitals are designated	Molecular orbitals are designated
	as <i>s</i> , <i>p</i> , <i>d</i> , etc.	as σ, σ*, π, π*, etc.

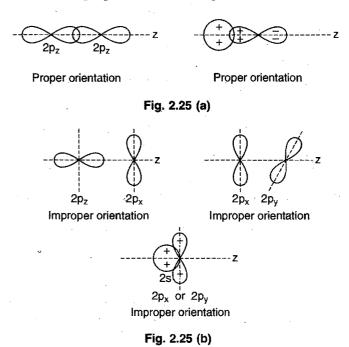

## Comparison of Bonding and Antibonding Molecular Orbitals

Bonding molecular orbitals	Antibonding molecular orbitals
combination of two atomic	It is formed by linear combination of two atomic orbitals when their wave functions are subtracted.
2. Its energy is less than the combining atomic orbitals.	Its energy is more than the combining atomic orbitals.
3. It increases the electron density between the nuclei. It therefore stabilises the molecule.	It decreases the electron density between the nuclei. It therefore destabilises the molecule.
4. It has no nodal plane (plane where electron density is zero).	It has nodal plane. It is symmetrical about inter-
5. It is symmetrical about internuclear axis.	nuclear axis and about a line perpendicular to it.
6. Designated by $\sigma$ , $\pi$ , $\delta$ , etc.	Designated by σ, π, δ, etc.

## Conditions for Combination of Atomic Orbitals to form Molecular Orbitals

The formation of molecular orbitals by linear combination of atomic orbitals can take place only if the following conditions are fulfilled:

- (i) The combining atomic orbitals must have same or nearly same energy, *i.e.*, comparable energy. For homonuclear diatomic molecule,  $A_2$ , 1s atomic orbital of one atom can combine with 1s atomic orbital of another atom or 2s can combine with 2s, 2p with 2p and so on. 1s cannot combine with 2s or 2s cannot combine with 2p as the energy difference is appreciably high. However, such combination can take place for heteronuclear diatomic molecules, AB, if the energy difference is not very high.
- (ii) The combining atomic orbitals must have proper orientation, *i.e.*, same symmetry about the molecular axis. For example, taking z-axis as the molecular axis,  $2p_z$  orbital of one atom can overlap with  $2p_z$  orbital of another atom but not with  $2p_x$  or  $2p_y$  orbitals because of their different symmetries. Similarly 2s orbital of one atom can overlap with  $2p_z$  orbital but not with  $2p_x$  or  $2p_y$  orbital of another atom on account of improper orientation (Fig. 2.25 a and 2.25 b).

(iii) The combining atomic orbitals must overlap to the maximum extent. Greater the extent of overlap, the greater will be the electron density between the nuclei of a molecular orbital.

#### Salient Features of Molecular Orbital Theory

From the above discussion, the main features of the molecular orbital theory can be summed up as follows:

- (i) Like valence bond theory, this theory starts with atomic orbitals but the atomic orbitals of the atoms approaching for bonding overlap to undergo constructive interference as well as destructive interference to form molecular orbitals. As a result, the atomic orbitals lose their individual identity and all the electrons in the molecule are associated with molecular orbitals.
- (ii) When two atomic orbitals overlap, they form two new orbitals called molecular orbitals. One of which is called bonding molecular orbital and other is called antibonding molecular orbital. These are formed by addition and subtraction of wave functions respectively.
- (iii) Molecular orbitals are the energy states of a molecule in which the electrons of the molecule are filled.
- (iv) Bonding molecular orbital has energy lower than the combining atomic orbitals while antibonding orbital has higher energy than the combining atomic orbitals.
- (v) Only those atomic orbitals can overlap to form molecular orbitals which have comparable energies and proper orientation.
- (vi) Electrons present in the bonding molecular orbital contribute towards the stability of molecule while electrons present in antibonding molecular orbital contribute to the repulsions between the nuclei of the atoms.
- (vii) The bonding molecular orbitals are denoted as  $\sigma$ ,  $\pi$ ,  $\delta$ , etc., while antibonding molecular orbitals are denoted as  $\sigma^*$ ,  $\pi^*$ ,  $\delta^*$ , etc.
- (viii) A molecular orbital (bonding or antibonding cannot accommodate more than two electrons. Both the electrons must have opposite spins (Pauli's exclusion principle).
- (ix) Molecular orbitals are filled in order of increasing energies starting with the orbital of minimum energy (aufbau principle).
- (x) In molecular orbitals of same energy (degenerate orbitals), the electron pairing occurs only when all of them are singly filled (Hund's rule).
- (xi) The shapes of the molecular orbitals formed depend upon the type of the combining orbitals.

### Types of Molecular Orbitals Formed

When the two atomic orbitals overlap along the internuclear axis, the molecular orbitals formed are called  $\sigma$  and  $\sigma^*$  molecular orbitals and when overlap sideways, the molecular orbitals formed are called  $\pi$  and  $\pi^*$  molecular orbitals. As s-orbitals are spherical symmetrical, their wave function has same sign in all directions while in case of p-orbitals, one lobe is given '+' sign and other a '-' sign. Overlapping of '+' lobes or '-' lobes of two p-orbitals forms bonding molecular orbital and overlapping of one '+' lobe of one orbital and '-' lobe of other orbital forms antibonding

molecular orbital. '+' lobe interaction with '+' lobe means addition of wave functions while '+' lobe interaction with '-' lobe means subtraction of wave functions. Few simple cases of combination of atomic orbitals are discussed:

(i) Molecular orbitals from s-atomic orbitals: The formation of molecular orbitals by linear combination of 1s atomic orbitals of two atoms is shown in Fig. 2.26.

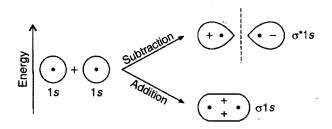

Fig. 2.26

The wave functions of two 1s atomic orbitals can combine in two ways:

- (a) When both have same sign, *i.e.*, addition of wave functions occur and  $\sigma$  1s molecular orbital is formed. This overlap takes place along the internuclear axis.
- (b) When both have opposite sign, *i.e.*, subtraction of wave functions occur and  $\sigma^*$  1s molecular orbital (antibonding) is formed. This overlap takes place also along the internuclear axis. The dotted line between the two lobes indicates a nodal plane where the probability of finding the electron density is zero.

Each of the two molecular orbitals can accommodate two electrons each and four in all. Similarly, the combination of two 2s-orbitals forms two molecular orbitals  $\sigma$ 2s (bonding)  $\overset{*}{\sigma}$ 2s (antibonding).

- (ii) Molecular orbitals from *p*-atomic orbitals: The two 2*p*-orbitals can combine together in either of the two ways, *i.e.*, end-to-end or side-by-side.
- (a) End-to-end overlap: Let z-axis be the line joining the two nuclei in the molecule. Thus, only  $2p_z$  orbitals will combine in end-to-end fashion. When  $2p_z$  orbitals on two atoms combine in phase (addition), bonding molecular orbital designated as  $\sigma 2p_z$  and when these overlap out of phase (subtraction), antibonding molecular orbital  $\sigma 2p_z$  come into existence. The formation is shown in Fig. 2.27.
- (b) Side-by-side overlap: When two  $2p_y$  orbitals or  $2p_x$  orbitals on two atoms, which have mutually parallel axis, interact to give rise molecular orbitals that are not symmetrical about nuclear axis and are called  $\pi$ -molecular orbitals. These are designated as  $\pi 2p_y$  (bonding) and  $\pi 2p_y$  (antibonding). Similarly, when two  $2p_x$  orbitals on the two atoms interact they form two  $\pi$ -molecular orbitals which are designated as  $\pi 2p_x$  (bonding) and  $\pi 2p_x$  (antibonding). The formation has been shown in Fig. 2.27.

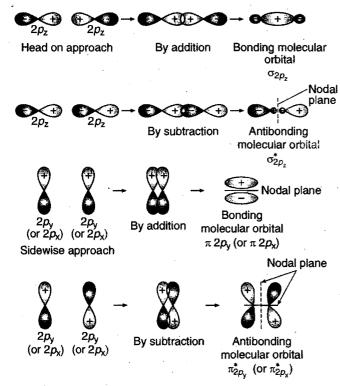

Fig. 2.27 Combination of two 2p atomic orbitals

Thus, in all there are six molecular orbitals arising from two sets of 2p atomic orbitals. Since,  $2p_y$  and  $2p_x$  atomic orbitals on an atom are degenerate (equal energy), the  $\pi$  molecular orbitals formed by these orbitals will also be degenerate, *i.e.*, bonding orbitals,

 $\pi 2p_y$  and  $\pi 2p_x$  have same energy. Similarly  $\pi 2p_y$  and  $\pi 2p_x$  have same energy.

It may be noted that whereas  $\pi 2p_x$  has only one nodal plane, there are two nodal planes in  $\pi 2p_x$  molecular orbital. Similar is the situation with  $\pi 2p_y$  and  $\pi 2p_y$  also.

#### Difference between sigma and pi molecular orbitals

Sigma ( <del>o</del> ) molecular orbital	pi (π) molecular orbital
It is formed by end-to-overlap of atomic orbitals alo the internuclear axis.	It is formed by sidewise overlap of atomic orbitals perpendicular to internuclear axis.
2. The overlapping is maximu	m. The overlapping is comparatively less.
-	to The orbital is not symmetrical to xis. rotation about internuclear axis.
4. It consists of one electron clo	ud. It consists of two electron clouds one above and other below the plane passing through the nuclei.

## Energy Level Diagrams for Molecular Orbitals

The relative energies of molecular orbitals depend on the following factors:

# (i) The energies of the atomic orbitals involved in the formation of molecular orbitals.

For example, pair of molecular orbitals formed by the combination of 2s atomic orbitals will have higher energy than those formed by combination of 1s orbitals. Similarly, molecular orbitals formed by combination of 2p atomic orbitals will have higher energy than those formed by combination of 2s atomic orbitals. Thus,

However, within same pair of molecular orbitals, the bonding molecular orbital has lower energy than the antibonding molecular orbital.

(ii) The extent of overlapping between the atomic orbitals. The greater the overlap, the more the bonding orbital is lowered and the antibonding orbital is raised in energy relative to atomic orbitals. Therefore, the energy of sigma molecular orbital is expected to be lower than pi molecular orbital.

2p orbitals form six molecular orbitals between two atoms.

Bonding orbitals 
$$\sigma 2p_z$$
,  $\pi 2p_x$ ,  $\pi 2p_y$   
Antibonding orbitals  $\sigma 2p_z$ ,  $\pi 2p_x$ ,  $\pi 2p_y$ 

The energy levels of these molecular orbitals have been determined experimentally by spectroscopic methods.

 $\pi 2p_x$  and  $\pi 2p_y$  orbitals have equal energies as these are degenerate orbitals.

 $\mathring{\pi}2p_x$  and  $\mathring{\pi}2p_y$  orbitals have equal energies as these are also degenerate orbitals.

 $\delta 2p_z$  has the maximum energy among the six 2p molecular orbitals.

The energy of  $\sigma 2p_z$  not definite. For diatomic molecules Li<sub>2</sub>, Be<sub>2</sub>, B<sub>2</sub>, C<sub>2</sub> and N<sub>2</sub>, the energy of  $\sigma 2p_z$  is higher than  $\pi 2p_x$  or  $\pi 2p_y$  while for diatomic molecules O<sub>2</sub>, F<sub>2</sub>, Ne<sub>2</sub>, the energy of  $\sigma 2p_z$  is lower than  $\pi 2p_x$  or  $\pi 2p_y$ .

Thus, the energy diagram for first ten molecular orbitals for diatomic homonuclear molecules such as  $\text{Li}_2$ ,  $\text{Be}_2$ ,  $\text{B}_2$ ,  $\text{C}_2$ ,  $\text{N}_2$  is :

$$\pi 2p_x$$
 $\pi 2p_x$ 
 $\pi 2p_x$ 
 $\pi 2p_x$ 
 $\pi 2p_z$ 
 $\pi 2p_y$ 
 $\pi 2p_y$ 
 $\pi 2p_y$ 

For homonuclear diatomic molecules such as  $O_2$ ,  $F_2$ ,  $Ne_2$ , the energy diagram is:

$$\pi 2p_x$$
  $\pi 2p_x$   $\pi 2p_x$   $\pi 2p_x$   $\pi 2p_z$   $\pi 2p_z$   $\pi 2p_y$   $\pi 2p_y$   $\pi 2p_y$ 

Energy increases

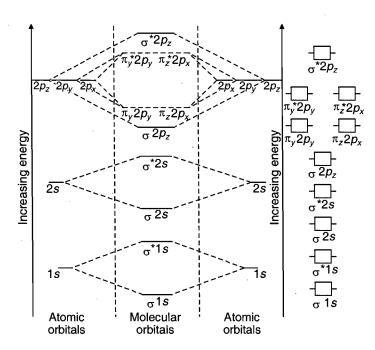

Fig. 2.28 Energy level diagram of molecular orbitals for homonuclear diatomic molecules (O<sub>2</sub>, F<sub>2</sub> and Ne<sub>2</sub>)

## Rules for Filling up of Molecular Orbitals with Electrons

- (i) The molecular orbitals are filled in increasing order of their energy (aufbau principle).
- (ii) The maximum number of electrons which can be accommodated in a molecular orbital is two (Pauli's exclusion principle).
- (iii) If there are two molecular orbitals having the same energy, the electrons will first enter these singly and when both achieve one electron each, pairing will start (Hund's rule).

# Electronic Configuration and Molecular Behaviour

The distribution of electrons among various orbitals is called the electronic configuration. Electronic configuration of the molecule can give the following information about the behaviour of the molecule.

- (i) Stability of molecules: A molecule is formed only when the total energy of the system decreases. This is only possible when bonding electrons are more than antibonding electrons. Suppose the number of electrons present in the bonding orbitals is represented by  $N_b$  and the number of electrons present in the antibonding orbitals  $N_a$ , then
- (a) If  $N_b$  is greater than  $N_a$  ( $N_b > N_a$ ), the molecule is stable. Stability is due to net force of attraction.
- (b) If  $N_b$  is less than  $N_a$  ( $N_b < N_a$ ), the molecule is unstable. Antibonding influence is stronger resulting in a net force of repulsion. This brings instability.

(c) If  $N_b$  is equal to  $N_a$  ( $N_b = N_a$ ), the molecule is unstable. This is because of the fact that the influence of antibonding electrons is slightly more than that of bonding electrons resulting in a net force of repulsion.

#### (ii) Stability in terms of bond order:

Bond order is defined as one half of the difference between the number of electrons present in the bonding and the antibonding orbitals, i.e.,

Bond Order (B.O.) = 
$$\frac{1}{2}$$
(N<sub>b</sub> - N<sub>a</sub>)  
Number of electrons Number of electrons in bonding orbitals – in antibonding orbitals

The bond order provides the following information.

- (a) If the value of bond order is positive, it indicates, a stable molecule or a stable ion. In case, the value of bond order is negative or zero, it indicates that the molecule or ion is unstable or the species does not exist.
- (b) The stability of the bond, *i.e.*, molecule or ion is measured in terms of **bond dissociation energy**. **The bond dissociation energy is directly proportional to the bond order**. Higher is the bond order, greater is the bond dissociation energy, *i.e.*, more is the stability. Thus, a molecule with bond order 3 is more stable than a molecule with a bond order 2 which in turn is more stable than a molecule with a bond order of 1 or  $1\frac{1}{2}$ .
- (c) Bond order 1, 2 and 3 means single, double and triple bonds respectively. [The difference between chemical bond and bond order is that chemical bond is always integral but bond order can be fractional also.]

Bond order Less than zero	Stability The species is highly unstable or does not exist
Zero	The species is highly unstable or does not exist
+ 1/2	The species exists but unstable
+1	A stable single bond
+2	A stable double bond
+3	A stable triple bond

(d) **Bond length is inversely proportional to the bond order.** Greater is the bond order, shorter is the bond length.

Molecule	Bond order	Bond dissociation energy (kJ mol <sup>-1</sup> )	Bond length (pm) <sup>2</sup>
$F_2 (F - F)$	1	158	142
$O_2$ (O = O)	2	497	121
$N_2 (N \equiv N)$	3	945	110

(iii) Magnetic nature: If all the electrons in the molecule or ion are paired, it is diamagnetic in nature. In case, if the molecule has any unpaired electron or electrons, it is paramagnetic in nature. Paramagnetic behaviour depends

upon the number of unpaired electrons, *i.e.*, greater the number of unpaired electrons present in the molecule or ion, greater is the paramagnetic nature. It is expressed in terms of magnetic moment which is equal to  $\sqrt{n(n+2)}$  B.M. Where n is the number of unpaired electrons.

## Molecular Orbital Configurations of Some Homonuclear Diatomic Species

Homonuclear diatomic molecules or ions have two identical atoms linked together. These are  $A_2$  type species.

(i) The hydrogen molecule ion,  $H_2^+$ : This ion has one hydrogen atom and one  $H^+$  ion linked together. Each has 1s-orbital. Using LACO method two 1s-orbitals will combine to give two molecular orbitals.  $\sigma(1s)$  and  $\overset{\star}{\sigma}(1s)$ , the only electron will be accommodated on  $\sigma 1s$ .

Thus, bond order for 
$$H_2^+ = \frac{1}{2}(1-0) = \frac{1}{2}$$

 $H_2^+$  ion can exist but it is unstable. It is paramagnetic in nature. The bond length is 104 pm. Its bond dissociation energy is 269 kJ mol<sup>-1</sup>.

(ii) The hydrogen molecule,  $H_2$ : It is formed from  $1s^1$  atomic orbitals of two atoms. The atomic orbitals  $(1s^1)$  will combine to form two molecular orbitals  $\sigma(1s)$  and  $\dot{\sigma}(1s)$ . Two electrons are accommodated on  $\sigma(1s)$  and  $\dot{\sigma}(1s)$  remains vacant.

Thus, bond order for 
$$H_2 = \frac{1}{2}(2-0) = 1$$

It is stable and diamagnetic in nature. It has single covalent bond. Its bond dissociation energy is 438 kJ mol<sup>-1</sup>. The bond length is 74 pm.

(iii) The hydrogen molecule ion,  $H_2$ : It is formed by linking hydrogen atom with hydrogen ion, H. Both have 1s-orbitals. These will combine to form two molecular orbitals  $\sigma(1s)$  and  $\mathring{\sigma}(1s)$ . These available electrons are accommodated as  $\sigma(1s)^2$  and  $\mathring{\sigma}(1s)^1$ .

Thus, bond order for 
$$H_2^- = \frac{1}{2}(2-1) = \frac{1}{2}$$

It is unstable and paramagnetic in nature.

(iv) Helium molecule,  $He_2^+$ : It is formed by linking helium atom with helium ion,  $He^+$ . Both have 1s-orbitals. These will combine to form two molecular orbitals  $\sigma(1s)$  and  $\sigma(1s)$ . Three electrons are accommodated as  $\sigma(1s)^2$  and  $\sigma(1s)^3$ .

Thus, bond order for 
$$He_2^+ = \frac{1}{2}(2-1) = \frac{1}{2}$$

The value of bond order indicates that  $He_2^+$  can exist but is unstable. The bond dissociation energy is 242 kJ mol<sup>-1</sup>. It is paramagnetic in nature. Both  $H_2^-$  and  $He_2^+$  have same number of electrons in the antibonding orbitals. Both have same stability, similar bond dissociation energy and similar bond lengths.

(v) Helium molecule, He<sub>2</sub>: It is formed by linking two helium atoms. Both have 1s-orbitals. These will combine to form two molecular orbitals  $\sigma(1s)$  and  $\sigma(1s)$ . Four available electrons are accommodated as  $\sigma(1s)^2$  and  $\sigma(1s)^2$ .

Thus, bond order for 
$$\text{He}_2 = \frac{1}{2}(2-2) = 0$$

Hence, there can be no possibility for the existence of  $\text{He}_2$  molecule.

(vi) Lithium molecule, (Li<sub>2</sub>): The electronic configuration of lithium atom (Z = 3) is  $1s^2 2s^1$ . Thus, total number of electrons in Li<sub>2</sub> molecule would be 6. The electronic configuration of Li<sub>2</sub> molecule may be written as:  $\sigma(1s)^2 \sigma(1s)^2 \sigma(2s)^2$ . This may be written as:  $KK [\sigma(2s)^2]$ . Where KK represents fully filled inner K shells in two atoms, *i.e.*,  $[\sigma(1s)^2]$   $[\dot{\sigma}(1s)^2]$ . These are also called non-bonding orbitals.

It is clear from the electronic configuration of  $\text{Li}_2$  molecule that there are 4 bonding electrons and 2 antibonding electrons.

Bond order 
$$=\frac{N_b - N_a}{2} = \frac{4 - 2}{2} = 1$$

Thus, Li<sub>2</sub> molecule is stable. It has one single sigma bond. The bond dissociation energy is 110 kJ mol<sup>-1</sup> and the bond length is 265 pm. As it has no unpaired electron, it is diamagnetic in nature. Li<sub>2</sub> molecules are found to exist in vapour state.

(vii) Be<sub>2</sub>, B<sub>2</sub> and C<sub>2</sub> molecules: The electronic configurations along with bond orders and magnetic nature of these molecules are given below:

Molecule	Total electrons	Configuration	Bond order	Magnetic nature
Be <sub>2</sub>	8	$KK[\sigma(2s)^2] \ [\overset{*}{\sigma}(2s)^2]$	$\frac{1}{2}(4-4)=0$	Does not exist
$B_2$	10	$KK[\sigma(2s)^2] \ [\mathring{\sigma}(2s)^2]$		
C <sub>2</sub>	12	$[\pi(2p_x)^1]$ $[\pi(2p_y)^1]$ $KK[\sigma(2s)^2]$ $[\overset{*}{\sigma}(2s)^2]$	$\frac{1}{2}(6-4)=1$	Paramagnetic
		$[\pi(2p_x)^2]$ $[\pi(2p_y)^2]$	$\frac{1}{2}(8-4)=2$	Diamagnetic

The bond in  $B_2$  is weak  $\pi$  bond. The Bond dissociation energy is 290 kJ mol<sup>-1</sup> and bond length is 159 pm.  $C_2$  molecule has double bond consisting both the  $\pi$  bonds as 4 electrons are present in pi molecular orbitals. Generally, in

most of the molecules, the double bond consists of one sigma and one pi bond. Like  $Li_2$  molecules,  $C_2$  molecules also exist in vapour state.

#### ■ Comparison of stabilities of H<sub>2</sub>, Li<sub>2</sub> and B<sub>2</sub>

The three molecules, *i.e.*,  $H_2$ ,  $Li_2$  and  $B_2$  possess the same value of bond order (*i.e.*, 1) but their stabilities are different.  $H_2$  molecule has maximum stability out of these molecules.

This can be explained as follows:

- (i) Li-Li bond length is much larger than H-H bond length.
- (ii) The overlapping of 2s–2s atomic orbitals in lithium is less effective than the overlapping of 1s–1s atomic orbitals in hydrogen.
  - (iii) Li<sub>2</sub> molecule has two electrons in antibonding orbital while H<sub>2</sub> has no electrons in the antibonding orbital.
- (iv) In Li<sub>2</sub> molecule, the electrons in  $\sigma(2s)$  molecular orbital are shielded by inner  $\sigma(1s)$  electrons. Thus, there is less attraction between electrons in  $\sigma(2s)$  and the nuclei.

Because of above reasons, Li<sub>2</sub> is less stable than H<sub>2</sub>.

Boron atom is smaller in size than Li atom and the  $B_2$  molecule has 6 electrons in the bonding orbitals while  $Li_2$  molecule has four electrons in the bonding orbitals. Hence,  $B_2$  is more stable than  $Li_2$ .

Thus, the order of stability is :  $H_2 > B_2 > Li_2$ 

(viii) Nitrogen molecule (N<sub>2</sub>): The electronic configuration of nitrogen is  $1s^2$ ,  $2s^2 2p^3$ . In nitrogen molecule, there are 14 electrons of which 4 are in the *K* shell and are non-bonding. Each atom contributes four atomic orbitals and thus, the molecule consists of 8 molecular orbitals. Then ten electrons are alloted to molecular orbitals as follows:

$$KK \sigma(2s)^2 \overset{*}{\sigma}(2s)^2 \pi(2p_x)^2 \pi(2p_y)^2 \sigma(2p_z)^2$$

where KK denotes the closed K shell structure  $\sigma(1s)^2 \overset{*}{\sigma}(1s)^2$ .

Bond order = 
$$\frac{1}{2}(8-2) = 3$$
 or =  $\frac{1}{2}(10-4) = 3$ 

Thus, nitrogen molecule has three bonds, one sigma and two pi. The molecule is diamagnetic. It has high bond dissociation energy  $(945 \text{kJ mol}^{-1})$  and bond length is 110 pm.

(ix)  $N_2^+$ ,  $N_2^-$  and  $N_2^2^-$  ions: The configurations of  $N_2^+$ ,  $N_2^-$  and  $N_2^2^-$  ions along with their bond orders, stability and their magnetic character are tabulated below:

· S	pecies	Total electrons	Configurations	Bond order	Stability	Magnetic nature
	N <sub>2</sub>	14	KK $\sigma(2s)^2 \mathring{\sigma}(2s)^2 \pi(2p_x)^2 \pi(2p_y)^2 \sigma(2p_z)^2$	$\frac{(8-2)}{2} = 3$	Most stable	Diamagnetic
	N <sub>2</sub> <sup>+</sup> .	· 13	KK $\sigma(2s)^2 \stackrel{*}{\sigma}(2s)^2 \pi(2p_x)^2 \pi(2p_y)^2 \sigma(2p_2)^1$	$\frac{(7-2)}{2}$ = 2.5	Less stable	Paramagnetic
	$N_2^-$	15	$KK \ \sigma(2s)^2 \stackrel{\star}{\sigma}(2s)^2 \pi(2p_x)^2 \pi(2p_y)^2 \ \sigma(2p_z)^2 \stackrel{\star}{\pi}(2p_x)^1$	$\frac{(8-3)}{2}$ = 2.5	Less stable	Paramagnetic
	$N_2^{2-}$	16	KK $\sigma(2s)^2 \stackrel{*}{\sigma}(2s)^2 \pi(2p_x)^2 \pi(2p_y)^2 \sigma(2p_z)^2 \stackrel{*}{\pi}(2p_x)^1 \stackrel{*}{\pi}(2p_y)^2$	(8-4) = 2	Least stable	Paramagnetic

Bond dissociation energies are directly proportional to the bond orders. The order of bond dissociation energies is :  $N_2 > N_2^+ = N_2^- > N_2^2^-$ . Bond length is inversely proportional to the bond order. The order of bond lengths is:  $N_2^{2^-} > N_2^- = N_2^+ > N_2$ .

(x) Oxygen molecule: The electronic configuration of oxygen is  $1s^2$ ,  $2s^2$   $2p^4$ . In oxygen molecule, there are 16 electrons of which 4 are in the K shell and are non-bonding. Each atom contributes four atomic orbitals and thus, the molecule consists of 8 molecular orbitals. The 12 electrons are alloted to molecular orbitals as follows:

KK 
$$\sigma(2s)^2 \mathring{\sigma}(2s)^2 \sigma(2p_z)^2 \pi(2p_x)^2 \pi(2p_y)^2 \mathring{\pi}(2p_x)^1 \mathring{\pi}(2p_y)^1$$

Note:  $\sigma(2p_z)$  is filled first and then  $\pi(2p_x)$  and  $\pi(2p_y)$  molecular orbitals are filled.

Bond order = 
$$\frac{(8-4)}{2}$$
 = 2

The oxygen molecule has two bonds (one sigma and one pi). The last two molecular orbitals are singly occupied, hence the molecule is paramagnetic in nature. The molecule is stable. The bond dissociation energy is 497 kJ mol<sup>-1</sup> and bond length is 121 pm.

(xi)  $O_2^+$ ,  $O_2^-$  and  $O_2^{2-}$  ions: The configurations of  $O_2^+$ ,  $O_2^-$  and  $O_2^{2-}$  ions along with their bond orders, stability and their magnetic character are tabulated ahead:

Species	Total electrons	Configurations	Bond order	Stability	Magnetic character
O <sub>2</sub>	16	KK $\sigma(2s)^2 \stackrel{\star}{\sigma}(2s)^2 \sigma(2p_z)^2 \pi(2p_x)^2 \pi(2p_y)^2 \stackrel{\star}{\pi}(2p_x)^1 \stackrel{\star}{\pi}(2p_y)^1$	$\frac{(8-4)}{2} = 2.0$	Most stable	Paramagnetic
$O_2^{+}$	15	KK $\sigma(2s)^2 \stackrel{*}{\sigma}(2s)^2 \sigma(2p_z)^2 \pi(2p_x)^2 \pi(2p_y)^2 \stackrel{*}{\pi}(2p_x)^1$	$\frac{(8-3)}{2}$ = 2.5	Most stable	Paramagnetic
$O_2^-$	17	$KK \; \sigma(2s)^2 \stackrel{*}{\sigma}(2s)^2 \; \sigma(2p_z)^2 \; \pi(2p_x)^2 \; \pi(2p_y)^2 \stackrel{*}{\pi}(2p_x)^2 \stackrel{*}{\pi}(2p_y)^1$	$\frac{(8-5)}{2} = 1.5$	- Less stable	Paramagnetic
O <sub>2</sub> -	18	$KK \ \sigma(2s)^2 \stackrel{\star}{\sigma}(2s)^2 \ \sigma(2p_z)^2 \ \pi(2p_x)^2 \ \pi(2p_y)^2 \stackrel{\star}{\pi}(2p_x)^2 \stackrel{\star}{\pi}(2p_y)^2$	$\frac{(8-6)}{2}$ = 1.0	Least stable	Diamagnetic

Bond order

Magnetic

nature

The bond dissociation energies and stability are in the given order:  $O_2^+ > O_2 > O_2^- > O_2^2$ The bond lengths are in the given order:  $O_2^{2-} > O_2^- > O_2^+$ 

(xii) Fluorine molecule: Electronic configuration of F-atom (Z = 9) is  $1s^22s^22p^5$ . Total number of electrons in  $F_2$  molecule is 18 of which 4 are in K shell and are non-bonding. Each atom contributes four atomic orbitals. The 14 electrons are alloted to molecular orbitals as follows:

KK 
$$\sigma(2s)^2 \stackrel{*}{\sigma}(2s)^2 \sigma(2p_z)^2 \pi(2p_x)^2 \pi(2p_y)^2 \stackrel{*}{\pi}(2p_x)^2 \stackrel{*}{\pi}(2p_y)^2$$
  
Bond order =  $\frac{8-6}{2}$  = 1

 $F_2$  molecule has one single bond. The molecule is diamagnetic as no unpaired electron is present in the molecule. The bond dissociation energy is 159 kJ  $\text{mol}^{-1}$  and bond length is 143 pm.

(xiii) Neon molecule (Ne<sub>2</sub>): The electronic configuration of neon atom is  $1s^22s^22p^6$ . In Ne<sub>2</sub> molecule 20 electrons are present, out of which four electrons are in K shell and are non-bonding. The molecular orbital configuration of neon molecule is:

$$KK \, \sigma(2s)^2 \, \mathring{\sigma}(2s)^2 \, \sigma(2p_z)^2 \, \pi(2p_x)^2 \, \pi(2p_y)^2 \, \mathring{\pi}(2p_y)^2 \, \mathring{\pi}(2p_y)^2 \, \mathring{\sigma}(2p_z)^2$$

Bond order = 
$$\frac{8-8}{2}$$
 = 0

Thus, Ne<sub>2</sub> molecule does not exist.

Diamagnetic Paramagnetic

### Structures of Heteronuclear Diatomic Molecules

Diamagnetic

The principles involved in the distribution of electrons in the heteronuclear diatomic molecules are the same as in homonuclear diatomic molecules. However, due to the difference in the electronegativity of two atoms, the molecular orbital diagrams will not be symmetrical. The electrons in bonding molecular orbital spend more time near the more electronegative atom. On the other hand, electrons in antibonding molecular orbital are closer to the less electronegative atom. Two examples are discussed below:

#### (i) Nitric oxide molecule (NO):

Total valence electrons = 5 + 6 = 11

The distribution of the electrons in various molecular orbitals of NO molecule is done in the following manner:

KK 
$$\sigma(2s)^2 \stackrel{*}{\sigma}(2s)^2 \sigma(2p_z)^2 \pi(2p_x)^2 \pi(2p_y)^2 \stackrel{*}{\pi}(2p_x)^1$$
  
Bond order =  $\frac{1}{2}(8-3) = 2.5$ 

The presence of one unpaired electron makes the molecule less stable. It is paramagnetic in nature.

Configuration of NO<sup>+</sup> (Valence electrons = 10)

KK 
$$\sigma(2s)^2 \stackrel{*}{\sigma}(2s)^2 \sigma(2p_z)^2 \pi(2p_x)^2 \pi(2p_y)^2$$
  
Bond order  $=\frac{1}{2}(8-2)=3$ 

Configuration of NO<sup>-</sup> (Valence electrons = 12)  
KK 
$$\sigma(2s)^2 \, \mathring{\sigma}(2s)^2 \, \sigma(2p_z)^2 \, \pi(2p_x)^2 \, \pi(2p_y)^2 \, \mathring{\pi}(2p_x)^1 \, \mathring{\pi}(2p_y)^1$$
  
Bond order =  $\frac{1}{2}(8-4) = 2$ 

#### (ii) Carbon monoxide molecule (CO):

Total valence electrons = 4 + 6 = 10

The distribution of electrons in various molecular orbitals of CO molecule is done in the following manner:

$$(\sigma 2s)^2 (\mathring{\sigma} 2s)^2 (\pi 2p_x)^2 (\pi 2p_y)^2 (\sigma 2p_z)^2$$
  
Bond order =  $\frac{1}{2}(8-2) = 3$ 

It represents one sigma bond and two  $\pi$ -bonds. The molecule is stable and diamagnetic in nature.

#### (iii) CN ion:

Total number of valence electrons = 10The configuration of CN $^{-}$  ion is:

KK 
$$\sigma(2s)^2 \mathring{\sigma}(2s)^2 \pi (2p_x)^2 \pi (2p_y)^2 \sigma (2p_z)^2$$
  
Bond order  $=\frac{1}{2}(8-2)=3$ 

The ion is stable and diamagnetic in nature.

#### (iv) BN molecule:

Total number of valence electrons = 8 The configuration of BN molecule is:

KK 
$$\sigma(2s)^2 \mathring{\sigma}(2s)^2 \pi (2p_x)^2 \pi (2p_y)^2$$
  
Bond order  $= \frac{1}{2}(6-2) = 2$ 

The molecule is stable and diamagnetic in nature.

# Comparison of Valence Bond Theory and Molecular Orbital Theory

#### Points of resemblance

- (i) For the covalent bond formation, orbital overlap is necessary in both the theories.
- (ii) The orbitals responsible for overlapping must have nearly same energies and proper orientation according to both the theories.
- (iii) According to both the theories, the electron density is high in the region between the atomic nuclei.
- (iv) Both the theories account for the directional nature of the bond.
- (v) Both the theories predict the non-existence of He<sub>2</sub> and Ne<sub>2</sub> molecules.
  - (vi) Both the theories are approximate.

#### Points of difference

- (i) In valence bond theory, atomic orbitals of the combining atoms do not lose their individual character to a great extent but in molecular orbital theory atomic orbitals of the combining atoms lose their identity and new molecular orbitals come into existence.
- (ii) According to valence bond theory electron density increases in the region of overlap while in molecular orbital

theory, there is increase as well as decrease in electron density in the region of orbital overlap.

- (iii) In valence bond theory, resonance plays its part while in molecular orbital theory resonance has no role to play.
- (iv) Mathematically, valence bond theory is quite easy to apply while molecular orbital theory is difficult to apply.
- (v) Valence bond theory does not explain paramagnetic nature of  $O_2$  molecule while molecular orbital theory explains the paramagnetic behaviour of  $O_2$  molecule.
- (vi) Valence bond theory fails to explain the existence of  $H_2^+$  ion while molecular orbital theory explains the existence of  $H_2^+$  ion.

## 2.35 METALLIC BONDING

In a metal crystal, one atom is surrounded by 8 or 12 other metal atoms. (This has been shown by X-ray study of metal crystals.) Since, in metals, the valency electrons are few, it is not possible for an atom to form 8 or 12 covalent bonds with neighbouring atoms.

In a metal crystal, all atoms are identical. These atoms cannot be linked by electrovalent bonds as all have same electronegativity. Thus, in metals, the atoms are bonded with each other with a special type of bonding known as metallic bonding. A theory was proposed by Drude in 1900 and modified by Lorentz in 1923, to explain the type of bonding in metals. This theory is known as electron cloud or electron pool or electron-gas theory. Since, the metals are electropositive as the ionisation energies are low, readily lose their valence electrons and converted into positive ions. These electrons move from place to place through the empty valence orbitals of the closed-packed metal ions and are shared simultaneously among all of them. Thus, these electrons link all the atoms together forming a characteristic type of bond, called the metallic bond. As the shared electrons are delocalised, the metallic bond has neither direction nor saturation. There are two essential conditions for metallic bonding. These conditions are:

- (a) The metal atoms should have low ionisation energy.
- (b) There should be sufficient number of vacant orbitals in the valency shell.

The bonding which holds the metal atoms firmly together on account of the force of attraction between metal ions and the mobile electrons is called metallic bonding.

The strength of the metallic bond depends on the number of valency electrons and the charge on the nucleus. As these increase, the metallic bond becomes stronger. It provides an answer to the fact that alkali metals are soft and have low melting and boiling points while transition metals are hard and have high melting and boiling points. The metallic bond is usually a strong bond. This explains the hardness, high melting and boiling points and low volatility of metals. The presence of mobile electrons in the metal crystal explains the main properties of metals such as electrical conductivity, thermal conductivity, metallic lustre, malleability and ductility.

# SOME:SOLVED PROBLEMS

**Problem 1.** (a) Why a molecule is more stable in terms of energy than the uncombined atoms?

#### Solution:

When the atoms combine together to form a molecule, there is always release of energy. Thus, potential energy of a molecule is less than that of uncombined atoms and therefore, the molecule is more stable.

(b) Why sodium chloride does not conduct electricity in solid state but does so in molten state?

#### Solution:

Solid sodium chloride has crystalline structure in which the ions are not free to move. The ions become mobile when it is in molten state and thus, the electricity can be conducted.

(c) Why  $H_2O$  is a liquid while  $H_2S$  is a gas at ordinary temperature?

#### Solution:

Oxygen has high electronegativity than sulphur. As a result,  $H_2O$  forms hydrogen bonding. Consequently, molecules of water come nearer to each other through hydrogen bonding. This results in higher boiling point of water and hence it is a liquid.

(d) The density of ice is less than that of water or ice floats over water. Explain.

#### Solution:

In ice, water molecule is associated with four other molecules through hydrogen bonding in a tetrahedral manner, *i.e.*, it has open-cage like structure in which lesser molecules are packed per mL. When ice melts, the molecules come closer to one another. Consequently the density of water in liquid state is more than in solid state. Thus, ice floats over water.

(e) Methanoic acid, HCOOH, has one carbon-oxygen bond of length 123 pm, and another of 136 pm. Which bond has which length?

#### Solution:

The structure of the molecule is:

The double bonded carbon-oxygen bond is shorter than the other. A double bond between two atoms is always stronger and shorter than a single bond between the same atoms.

(f) Both carbon-oxygen bonds in the methanoate ion, HCOO<sup>-</sup>, have the same length (127 pm). What does this tell about bonding?

#### Solution:

This is due to the presence of resonance in the molecule.

$$H-C \bigcirc O \longrightarrow H-C \bigcirc O$$

Each bond has part of the character of single bond and part of character of a double bond. The electrons are delocalised over the three atoms.

$$H-C\langle O \rangle$$

(g) Water can react with hydrogen ion to make the oxonium ion,  $H_3O^+$ . What is present in water molecule that allows it to react with a hydrogen ion? Describe the bonding in the oxonium ion. Draw a dot and cross diagram for the molecule.

#### Solution:

There are two lone pairs, but only one of them makes a coordinate bond with an empty 1s-orbital on a hydrogen atom.

There are three bonds in the  $\mathrm{H_3O}^+$  ion, all the three are identical but two of them are covalent and one coordinate. The dot and cross diagram is:

**Problem 2.** Draw dot and cross diagrams for the following molecules. Then, use electron repulsion theory to predict their shapes.

(i) CCl<sub>4</sub>, (ii) H<sub>2</sub>S, (iii) NF<sub>3</sub>, (iv) NO, (v) AlCl<sub>3</sub>.

Solution:

(i) CCl<sub>4</sub>

Four bond pairs + no lone pairs = 4 Shape—tetrahedral

(ii) H<sub>2</sub>S

Two bond pairs + two lone pairs = 4
Shape—bent like water

(iii) NF<sub>3</sub>

Three bond pairs + one lone pair = 4 Shape—pyramidal like NH<sub>3</sub>

(iv) NO

Shape—Linear (All diatomic molecules must be linear)

(v) AlCl<sub>3</sub>

Three bond pairs + no lone pair = 3 Shape—triangular planar like BCl<sub>3</sub>

Problem 3. Arrange the following in order of increasing:

- (a) dipole moment H<sub>2</sub>O, H<sub>2</sub>S, BF<sub>3</sub>
- (b) covalent character LiCl, LiBr, LiI
- (c) covalent character NaCl, MgCl2, AlCl3

#### Solution:

(a) BF<sub>3</sub> is a symmetrical molecule. It has zero dipole moment. Oxygen being more electronegative than S, bond moment of O—H is more than S—H. So, the dipole moments are in the order of

$$BF_3 < H_2S < H_2O$$

(b) The anion size in increasing order is

$$Cl^- < Br^- < I^-$$

Hence, LiCl is least covalent and LiI most. The order is

(c) Cation size in decreasing order is

$$Na^{+} > Mg^{2+} > Al^{3+}$$

Thus, Al<sup>3+</sup> ion has maximum polarisation effect and Na<sup>+</sup> ion has least. Thus, the covalent order is

**Problem 4.** Write the electron configurations and calculate the bond order of  $H_2^+$ ,  $H_2$  and  $He_2$ . Explain why bond length in  $H_2^+$  is longer than in  $H_2$ ?

#### Solution:

The number of electrons, their configurations, etc., for the given species are:

Species	No. of electrons	Configuration	N <sub>b</sub>	Na	Bond order $= 1/2[N_b - N_a]$
$H_2^+$	1	(ols)1	1	0	1/2
$H_2$	2	$(\sigma ls)^2$	-2	0	. 1
He <sub>2</sub>	4	$(\sigma ls)^2 (\sigma ls)^2$	2	2	.0.

The bond length in  $H_2^+$  is longer than in  $H_2$  because in  $H_2^+$  only one electron is present to shield the two nuclei from mutual repulsion. In  $H_2$  there are two electrons to hold the two nuclei thus nuclear repulsion is less than that in  $H_2^+$ . Hence, nuclear separation in  $H_2^+$  is more than in  $H_2$ .

**Problem 5.** (a) A diatomic molecule has a dipole moment of 1.2 D. If the bond distance is 1.0 Å, what fraction of an electronic charge, e, exists on each atom?

#### Solution:

Partial charge = 
$$\frac{\text{Dipole moment}}{\text{Bond distance}} = \frac{1.2 \times 10^{-18} \text{ esu cm}}{1.0 \times 10^{-8} \text{ cm}}$$
  
=  $1.2 \times 10^{-10} \text{ esu}$ 

The fraction of an electronic charge

$$= \frac{1.2 \times 10^{-10}}{4.8 \times 10^{-10}} = 0.25 = 25\% \text{ of } e.$$

(b) The dipole moment of LiH is  $1.964 \times 10^{-29}$  cm and the interatomic distance between Li and H in this molecule is  $1.596 \, \mathring{A}$ . What is the per cent ionic character in LiH?

#### Solution:

The dipole moment of 100% ionic molecule (Li<sup>+</sup>H<sup>-</sup>) = (1 electronic charge) (interatomic distance)

= 
$$(1.602 \times 10^{-19} )$$
 C)  $(1.596 \times 10^{-10} )$  m)

$$= 2.557 \times 10^{-29} \,\mathrm{Cm}$$

Fractional ionic character

Exp. value of dipole moment
Theoretical value of dipole moment
$$= \frac{1.964 \times 10^{-29}}{2.557 \times 10^{-29}} = 0.768$$

The bond in LiH is 76.8% ionic.

**Problem 6.** Interpret the non-linear shape of  $H_2S$  molecule and non-planar shape of  $PCl_3$  using valence shell electron pair repulsion (VSEPR) theory. [I.I.T. 1998]

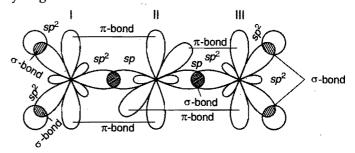

### Solution:

In  $H_2S$ , two bonded pairs and two lone pairs are present, *i.e.*, sulphur is in  $sp^3$  hybridized state. The angle is less than  $109^{\circ}28'$  as contraction occurs due to presence of lone pairs. Thus,  $H_2S$  has V-shaped structure. In  $PCl_3$ , three bonded pairs and one lone pair are present, *i.e.*, phosphorus is also in  $sp^3$  hybridized state but it has pyramidal structure.

**Problem 7.** Discuss the hybridization of carbon atoms in allene  $(C_3H_4)$  and show the  $\pi$ -orbital overlaps. [I.I.T. 1999]

#### Solution:

Allene is  $CH_2$ —C— $CH_2$  carbon atoms I and III are in  $sp^2$  hybridized state while carbon II is in sp hybridized state. Two unhybridized orbitals of carbon II overlap sidewise with unhybridized orbital of each of carbon I and carbon III to form  $\pi$ -bonds besides it also forms a sigma bond with each of the carbon atoms using hybridized orbitals. Two hybridized orbitals of each of carbon I and III form sigma bonds with hydrogen atoms.

**Problem 8.** Explain why o-hydroxybenzaldehyde is a liquid at room temperature while p-hydroxybenzaldehyde is a high melting solid. [1.1.T. 1999]

Solution: o-hydroxybenzaldehyde show intramolecular hydrogen bonding whereas p-hydroxybenzaldehyde has intermolecular hydrogen bonding. Thus, p-hydroxy-benzaldehyde is an aggregate of a number of molecules and therefore, it is a high melting solid.

$$\bigcirc C = O_{\delta-}$$

$$C = O_{\delta-}$$

$$O = C$$

(o-hydroxybenzaldehyde) Intrahydrogen bonding

Interhydrogen bonding (p-hydroxybenzaldehyde aggregate)

**Problem 9.** In the equation,  $A + 2B + H_2O \longrightarrow C + 2D$  $(A = HNO_2, B = H_2SO_3, C = NH_2OH)$ , identify D. Draw the structures of A, B, C and D. [I.I.T. 1999]

#### Solution:

Solution:

$$HNO_2 + 2H_2SO_3 + H_2O \rightarrow NH_2OH + 2H_2SO_4$$

(A) (B) (C) (D)

Structures—(A) HNO<sub>2</sub>; HO—N=O,

(B) H<sub>2</sub>SO<sub>3</sub>; HO—S→O, (C) NH<sub>2</sub>OH; H—N—OH,

OH O H

(D) H<sub>2</sub>SO<sub>4</sub>; HO—S

**Problem 10.** Write the M.O. electron distribution of  $O_2$ . Specify its bond order and magnetic property.

#### Solution:

O<sub>2</sub> (No. of electrons = 16)  $KK(\sigma 2s)^2 (\sigma^2 2s)^2 (\sigma 2p_z)^2 (\pi 2p_u)^2$  $(\pi 2p_x)^2(\mathring{\pi}2p_y)^1(\mathring{\pi}2p_x)^1$ 

Bond order = 
$$\frac{1}{2}(8-4) = 2$$

As two of the orbitals are singly occupied, the molecule is paramagnetic in nature.

**Problem 11.** Which of the two peroxide ion or superoxide ion has larger bond length?

#### Solution:

The bond length in a molecule is dependent on bond order. The higher is the bond order, smaller will be the bond length. Peroxide ion,  $O_2^{2-}$ 

O<sub>2</sub><sup>2</sup>: 
$$KK(\sigma 2s)^2 (\mathring{\sigma} 2s)^2 (\sigma 2p_z)^2 (\pi 2p_y)^2 (\pi 2p_x)^2 (\mathring{\pi} 2p_y)^2 (\mathring{\pi} 2p_x)^2$$
  
Bond order =  $\frac{8-6}{2}$  = 1

Superoxide ion,  $O_2^-$ 

O<sub>2</sub>: 
$$KK(\sigma 2s)^2(\mathring{\sigma}2s)^2(\sigma 2p_z)^2(\pi 2p_y)^2(\pi 2p_x)^2(\mathring{\pi}2p_y)^2(\mathring{\pi}2p_x)^1$$
  
Bond order =  $\frac{8-5}{2}$  = 1.5

Bond order of superoxide ion is higher than peroxide ion, hence bond length of peroxide ion is larger.

Problem 12. Which d-orbital is involved in hybridization?

#### Solution:

 $d_{x^2-y^2}$ . This is because its four lobes lie along the x-axis and *y*-axis. The two *p*-orbitals can combine along these axes.

**Problem 13.** What is the hybrid state of BeCl<sub>2</sub>? What will be the change in the hybrid state of Be in BeCl<sub>2</sub> in the solid state?

[C.B.S.E. (P.M.T.) 2005]

#### Solution:

In the vapour state, BeCl<sub>2</sub>, exists as a linear molecule, Cl - Be - Cl, i.e., Be is in sp hybridized state. In the solid state, it has a polymeric structure. Each Be atom is linked with 4 Cl atoms, two by covalent bonds and two by coordinate bonds.

Thus, Be atom is in  $sp^3$  hybridized state. Two empty orbitals and two half filled orbitals, i.e., in all four orbitals undergo hybridization.

**Problem 14.** (a) How bond energy varies from  $N_2^-$  to  $N_2^+$  and why?

- (b) On the basis of molecular orbital theory what is similarity between
  - (i)  $F_2$  and  $O_2^{2-}$  (ii)  $CO, N_2, NO^+$ ? [C.B.S.E. (P.M.T.) 2004] Solution:
- (a) Bond energy of  $N_2^+$  = Bond energy of  $N_2^-$  because bond order is same in both the species. [However,  $N_2^+$  is slightly more stable than  $N_2^-$  as antibonding electrons number is higher in  $N_2^-$  than in  $N_2^+$ .]
- (b) (i) Both  $F_2$  and  $O_2^{2-}$  have same bond order same bond length and are diamagnetic.
- (ii) These are isoelectronic species, possess same bond order and same bond length.

Problem 15. Arrange the following compounds in the increasing order of bond length of O—O bond in  $O_2$ ,  $O_2[AsF_6]$ ,  $KO_2$ .

Explain on the basis of ground state electronic configuration of dioxygen in these molecules. [I.I.T. 2004]

#### Solution:

 $O_2[AsF_6]$  has  $O_2^+$  ion while  $KO_2$  has  $O_2^-$  ion.

E.C. of 
$$O_2 = KK\sigma(2s)^2 \mathring{\sigma}(2s)^2 \sigma(2p_z)^2 \pi(2p_x)^2 \pi(2p_y)^2$$

$$\pi(2p_x)^1 \pi(2p_y)^1$$

E.C. of 
$$O_2^+ = KK \sigma(2s)^2 \dot{\sigma}(2s)^2 \sigma(2p_z)^2 \pi(2p_x)^2 \pi(2p_y)^2$$

E.C. of 
$$O_2^- = KK \sigma(2s)^2 \mathring{\sigma}(2s)^2 \sigma(2p_z)^2 \pi(2p_x)^2 \pi(2p_y)^2 \mathring{\pi}(2p_x)^2 \mathring{\pi}(2p_y)^1$$

B.O. of 
$$O_2 = 1/2 (8-4) = 2$$

B.O. of 
$$O_2^+ = 1/2 (8-3) = 2.5$$

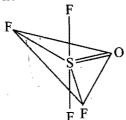

B.O. of 
$$O_2^- = 1/2(8-5) = 1.5$$

Higher is the B.O., smaller is the bond length. Hence, order of O—O bond length is

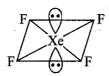

$$O_2^+ > O_2 > O_2^-$$
, i.e.,  
 $O_2[AsF_6] > O_2 > KO_2$ 

**Problem 16.** Using VSEPR, draw the molecular structures of OSF<sub>4</sub> and XeF<sub>4</sub> indicating the position of lone pairs and hybridization of central atoms. [I.I.T. 2004]

#### Solution:

Square planar shape  $(sp^3d^2)$  hybridization

**Problem 17.** Which of the following species have same shape and same bond order?

$$N_3$$
,  $NO_2$ ,  $CO_2$ ,  $O_3$ 

#### Solution:

Isoelectronic species possess same shape and same bond order.

 $CO_2$  and  $N_3$  are isoelectronic = 22 electrons

Similarly,  $NO_2^-$  and  $O_3$  are isoelectronic = 24 electrons

Thus,  $CO_2$  and  $N_3^-$  have same shape and bond order and similarly,  $NO_7^-$  and  $O_3$  have same shape and bond order.

**Problem 18.** Apply VSEPR theory to predict the shapes of  $SF_4$ ,  $ICl_3$ ,  $PbCl_2$  and  $NH_4^+$ .

**Solution:** The Lewis structure of SF<sub>4</sub> is:

S atom is surrounded by five electron pairs (4 bonded and one lone pair) thus, the geometry is trigonal bipyramidal. The actual shape is see-saw.

The Lewis structure of ICl3 is:

Iodine is surrounded by five electron pairs (3 bonded and two lone pairs). Thus, the geometry is trigonal bipyramidal. The actual shape is T-shape.

The Lewis structure of PbCl<sub>2</sub> is:

Pb is surrounded by three electron pairs (2 bonded and one lone pair). Thus, the geometry is trigonal planar. The actual shape is V-shape, *i.e.*, bent structure.

The Lewis structure of NH<sup>+</sup><sub>4</sub> ion is:

$$\begin{bmatrix} H & H \\ H & N & H \\ \bullet & H \end{bmatrix}^{\dagger}$$

Nitrogen is surrounded by four bonded pairs. The shape is thus tetrahedral.

**Problem 19.** Arrange the following in order of (i) increasing N—O bond length (ii) increasing bond angles.

Give reasons.

$$NO_{2}^{+}$$
,  $NO_{2}^{-}$ ,  $NO_{3}^{-}$ 

#### Solution:

Type of hybridization of central atom, *i.e.*, N atom in NO $_2^+$  is sp hybridized while in NO $_2^-$  and NO $_3^-$ , it is  $sp^2$  hybridized. Their structures are:

**Problem 20.** Give reasons for the following observations:

- (a) Sucrose is a covalent compound but it is quite soluble in water.
- (b) Hydrogen bonding does not exist in HCl though chlorine is quite electronegative.
  - (c) o-Nitrophenol has lower boiling point than p-nitrophenol.

#### Solution:

- (a) The molecule of sucrose contains many —OH groups and hence are capable of forming H-bonds with water.
  - (b) This is due to large size of Cl-atom.
- (c) *p*-nitrophenol has higher boiling point due to intermolecular H-bonding.

**Problem 21.** Indicate the type of bonds present in  $NH_4NO_3$  and state mode of hybridization of two N-atoms in it.

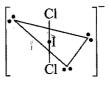

#### Solution:

 $NH_4NO_3$  is an ionic compound in which cation is  $NH_4^+$  ion and anion is  $NO_3^-$  ion. In  $NH_4^+$  ion, three covalent bonds and one coordinate bond is present. The nitrogen is in  $sp^3$  hybrid state, *i.e.*, the species is tetrahedral. In  $NO_3^-$ , nitrogen is in  $sp^2$  hybrid state, *i.e.*, the species is trigonal planar. One oxygen is linked by a double bond, other by a covalent bond and third by a coordinate bond.

**Problem 22.** Explain the shape of  $ICl_{\frac{1}{2}}$  ion.

#### Solution:

Type of hybridization, H = 1/2 [7 + 2 - 0 + 1] = 5, *i.e.*,  $sp^3d$ -hybridization. The central atom 'I' undergoes  $sp^3d$  hybridization. The electron configuration of I-atom in ground state is  $5s^2 5p_x^2 5p_y^2 5p_z^1 5d^0$ . It undergoes hybridization giving five hybrid orbitals. Three hybrid orbitals contain lone pair of electrons each and occupy equatorial positions of the trigonal bipyramid. One hybrid orbital is half filled, it overlaps with an orbital of chlorine atom and forms a covalent bond. One hybrid empty orbital accepts an electron pair from Cl-ion to form a coordinate bond. The Cl-atoms are present on axial positions.

# **SUMMARY AND IMPORTANT POINTS TO REMEMBER**

- 1. A chemical bond is defined as a force that acts between two or more atoms to hold them together as a stable molecule.
- 2. The term valency has been derived from the Latin word 'valentia' which means capacity. Each element was said to have a valency equal to its combining capacity. The number of hydrogen or chlorine atoms with which another atom combines is called its combining capacity. The valency term is now defined as the number of chemical bonds formed by an atom in a molecule. The modern concept believes that electrons are responsible for chemical combination. The atoms interact with each other on account of following reasons:
  - (a) Decrease in energy: Bonded state has lower potential energy than the unbonded state and hence more stable. When two atoms approach the net result should be attraction to form a chemical bond. No chemical bonding is possible if net result is repulsion.
  - (b) Lewis octet rule: The noble gases consist of filled outermost shells. Except for helium, whose electronic configuration is  $1s^2$ , the s- and p- subshells of the highest energy level contain a total of eight electrons. The  $s^2p^6$  configuration constitutes a structure of maximum stability and therefore, of minimum energy. The atoms of all elements when enter into chemical combination try to attain noble gas configuration. The tendency to achieve eight electrons in their outermost shell by atoms is known as Lewis octet rule. This is the basis of electronic theory of valency.

- 3. Electronic theory of valency was formulated by Kossel and Lewis and was completed by Langmuir.
  - The union of two or more atoms involving redistribution of electrons in their outershells (either by transference or sharing) in such a way, so that all the atoms acquire stable noble gas configuration of minimum energy is known as electronic theory of valency.

There are two ways by which the atoms can acquire noble gas configuration.

- (a) By losing or accepting electrons
- (b) By sharing electrons.

There are three types of bonds or linkages which hold the atoms together in a molecule.

- (i) Electrovalent bond
- (ii) Covalent bond
- (iii) Coordinate bond.
- 4. The chemical bond formed between two or more atoms as a result of the transfer of one or more electrons from electropositive to electronegative atom is called electrovalent bond. This bond is also called ionic or polar bond.

The bond formed between oppositely charged ions is called electrovalent bond. This bond is not possible between similar atoms.

5. The energy released when the requisite number of positive and negative ions are condensed into crystal to form 1 mole of the compound is called lattice energy. The force of attraction (*F*) between two oppositely charged ions in air with charges

equal to  $q_1$  and  $q_2$  and separated by a distance d is given by,

$$F = \frac{1}{4\pi\varepsilon_0 K} \cdot \frac{q_1 q_2}{d^2} \quad \text{or} \quad F = \frac{1}{4\pi\varepsilon_0 K} \cdot \frac{q_1 q_2}{(r_A^+ + r_B^-)^2}$$

where, K is dielectric constant of medium.

An ionic bond is purely electrostatic in nature. Its formation is favoured by (a) low ionisation potential of electropositive metal (b) high electron affinity of electronegative element and (c) high lattice energy.

The summation of these energies should be negative, i.e., energy is released.

$$I.P. + E.A. + L.E. = -ive$$
 or  $E.A. + L.E. > I.P.$ 

- 6. Compounds having electrovalent bonds are called electrovalent compounds. They have following general properties:
  - (i) Crystalline nature: Electrovalent compounds have closed packed structures and ions have no freedom of movement. These are not found in liquid or gaseous states under ordinary conditions of temperature and pressure and exist as solids. They have low volatility and high stability. They have high density and high melting and boiling points.
  - (ii) Hard and brittle
  - (iii) Fairly soluble in polar solvents and insoluble in non-polar solvents
  - (iv) Electrovalent solids do not conduct electricity
  - (v) Do not show stereo-isomerism
  - (vi) Show ionic reactions.
- 7. Variable electrovalency: Certain elements show more than one electrovalency in their electrovalent compounds. The following are two reasons for variable valency:
  - (a) Instability of the core: The residue configuration left after the loss of valency electrons is called a core or kernel. In the case of the atoms of transition elements, ions formed after the loss of valency electrons do not possess a stable core as the configuration of the outermost shell is not ns²np6 but ns²np6nd¹-10. This shell generally loses one or more electrons giving rise to metal ions of higher valencies.
  - **(b) Inert pair effect**: Some of the heavier representative elements of third, fourth and fifth groups having configurations of the outermost shell  $ns^2np^1$ ,  $ns^2$   $np^2$  and  $ns^2np^3$  show valencies with a difference of 2, *i.e.*, (1; 3), (2; 4), (3; 5) respectively. The reluctance of *s*-electron pair to take part in bond formation is known as inert pair effect.
- 8. Covalent bond: The second mode of combination was first proposed by Lewis in 1916. There are atoms which attain noble gas configuration by sharing one or more electron pairs when each atom contributes equally. The pair or pairs of electrons become a common property of both. Such a bond is possible between similar and dissimilar atoms. In this bond atoms do not acquire any charge. The electrons which are shared, occupy such a position in between the nuclei of the two atoms where there is maximum force of attraction from

- the two nuclei. The bond is termed a non-polar bond. Covalent bond may be single, double or a triple bond. Double and triple covalent bonds are called multiple covalent bond.
- O. Covalency: It is defined as the number of electrons contributed by an atom of the element for sharing with other atoms as to achieve noble gas configuration. The usual covalency of an element except hydrogen is equal to (8–group number to which the element belongs in Mendeleev's periodic table). This is true for 4th, 5th, 6th and 7th group elements. Generally, the covalency of an element is equal to the number of unpaired electrons in s- and p- orbitals of the valency shell. The elements having vacant d-orbitals in their valency shell like P, S, Cl, Br, I show variable covalency by increasing the number of unpaired electrons under excited conditions.
- 10. Covalent compounds: The compounds containing a covalent bond or a number of covalent bonds are termed covalent compounds. The characteristics of the covalent compounds are:
  - (i) These exist as gases or liquids under normal conditions as very weak attractive forces exist between the molecules, some exist as soft solids if the molecular masses are high.
  - (ii) With the exception of few having giant structures, others have relatively low melting and boiling points.
  - (iii) Covalent compounds are, in general, bad conductors of electricity.
  - (iv) Covalent compounds are insoluble in polar solvents and soluble in non-polar solvents. This is based on the principle 'Like dissolves like'.
  - (v) Show molecular reactions.
  - (vi) The covalent bond is rigid and directional. Covalent compounds show isomerism.
- 11. Coordinate bond is a special type of covalent bond. It is defined as a covalent bond in which both electrons of the shared pair are contributed by one of the two atoms. Such a bond is also called as dative bond. This bond is established between two such atoms, one of which has a complete octet and possesses a pair of valency electrons (donor) while the other is short of a pair of electrons (acceptor). The properties of coordinate compounds are intermediate between the properties of covalent compounds and electrovalent compounds.
- 12. There are several stable molecules such as BeCl<sub>2</sub>, BF<sub>3</sub>, PCl<sub>5</sub>, SF<sub>6</sub>, IF<sub>7</sub>, etc., in which octet rule is violated, *i.e.*, atoms in these molecules are either short of octet (less than 8 electrons in the valency shell) or more than octet.
- 13. Lewis dot formulae are used to represent atoms covalently bonded in a molecule or a polyatomic ion. Lewis dot formulae show only the number of valency electrons, the number and kinds of bonds but do not depict the three dimensional shapes of molecules and polyatomic ions. The formal charge on the atoms in a Lewis dot structure of a molecule or polyatomic ion can be calculated by the application of following formula:

Formal charge on = total number of valency electrons an atom in the free atom – total number of non-bonding electrons – 1/2 total number of bonding shared electrons

14. A covalent bond, in which electrons are shared unequally and the bonded atoms acquire a partial positive and negative charge is called a polar covalent bond. Bond polarity is described in terms of ionic character which usually increases with increasing difference in the electronegativity between bonded atoms.

Percentage of ionic character =  $[16 (X_A - X_B) + 3.5 (X_A - X_B)^2]$  where  $X_A$  and  $X_B$  are electronegativity of atoms A and B. 50% ionic character corresponds to  $(X_A - X_B)$  equal to 2.1.

15. The polarity of the molecule is indicated in terms of dipole moment. Dipole moment is defined as the product of the distance separating charges of equal magnitude and opposite sign with the magnitude of the charge.

 $\mu$  = electric charge × bond length =  $q \times d$ 

Dipole moment is measured in 'Debye' unit (D).  $1D = 10^{-18}$  esu cm =  $3.33 \times 10^{-30}$  coulomb metre. The value of dipole moment increases as the electronegativity difference in diatomic molecule increases. Greater the value of dipole moment of the molecule, greater the polarity of the bond between the atoms. The overall dipole moment of a polar molecule depends on the geometry and shape of the molecule.

Linear molecules like  $CO_2$ ,  $CS_2$ ,  $BeF_2$  and symmetrical molecules like  $BF_3$ ,  $CH_4$ ,  $CCl_4$ , etc., have zero dipole moment. Percentage of ionic character in a bond

= Experimental value of dipole moment × 100 Theoretical value of dipole moment

16. The attractive force that binds hydrogen atom of one molecule with electronegative atom of the other molecule of the same or different substance is known as hydrogen bond. Hydrogen bonding occurs when H-atom is linked to F, O or N atoms (i.e., with small size and high electronegativity). H-bond is usually longer than the covalent bond present in the molecule. Bond energy of hydrogen bond is in the range of 3 to 10 kcal mol<sup>-1</sup> (10 to 40 kJmol<sup>-1</sup>), i.e., about 1/10 the energy of the covalent bond. Hydrogen bond strength increases with the increase in electronegativity and decrease in size of the atom.

$$H - F - - H > H - O - - H > H - N - - - H$$

Hydrogen bond never involves more than two atoms. All the three atoms X—H---X lie in the straight line.

- 17. (a) In water, each O-atom is linked with four H-atoms, two by covalent bonds and two by hydrogen bonds.
  - (b) HF<sub>2</sub> (or KHF<sub>2</sub>) exists but HCl<sub>2</sub> (or KHCl<sub>2</sub>) does not because there is hydrogen bonding in HF but not in HCl.
  - (c) Cl has same electronegativity as N, yet there is no H-bonding in HCl because size of Cl is large.
  - (d) Intermolecular H-bonding results in increase in melting

- and boiling points whereas intramolecular H-bonding results in decrease in melting and boiling points.
- (e) Ice has maximum density at 4°C (277K).
- 18. When anions and cations approach each other, the valence shells of the anions are pulled towards cation nucleus and thus, the shape of anion is deformed. This phenomenon of deformation of anion by a cation is known as polarization and the ability of the cation to polarize a nearby anion is called as polarizing power of the cation.

Fajan observed that greater the polarization of the anion in the molecule, more is the covalent character in it.

- 19. Valence bond theory: This theory was presented by Heitler and London in 1927 to explain how a covalent bond is formed. The theory was extended by Pauling and Slater in 1931. The main points of the theory are:
  - (i) A covalent bond is formed by overlapping of atomic orbitals of valency shell of two atoms.
  - (ii) Only half filled atomic orbitals, i.e., orbitals singly occupied with opposite spins can enter into overlapping process. The resultant bond acquires a pair of electrons with opposite spins.
  - (iii) The atoms with half filled orbitals must come closer to one another with their axes in proper directions for overlapping.
  - (iv) As a result of overlapping, there is maximum electron density somewhere between the two atoms.
  - (v) Greater the overlapping, higher is the strength of the chemical bond. The amount of energy released per mole during overlapping is termed bond energy. This energy stabilizes the system.
  - (vi) Greater the overlapping, lesser will be the bond length.
  - (vii) Electrons which are already paired in valency shell can enter into bond formation if they can be unpaired first and shifted to vacant orbitals.
  - (viii) Two types of bonds are formed. These are (a) sigma (σ) and (b) pi (π) bond. Bond orbital which is symmetrical about the line joining the two nuclei is known as sigma bond. It is formed by head on or axial overlap. π-bonds are formed by the sidewise or lateral overlapping of p-orbitals.

 $\pi$ -bond is a weaker bond in comparison to sigma bond. The bond orbitals lie below and above the internuclear axis.  $\pi$ -bonds are formed only when  $\sigma$ -bond has already been formed.  $\pi$ -bonds are more reactive than sigma bonds. The shape of the molecule is decided by  $\sigma$ -bonds.  $\pi$ -electrons are mobile in nature. A double bond consists one  $\sigma$ -bond and one  $\pi$ -bond while a triple bond consists one  $\sigma$ -bond and two  $\pi$ -bonds. All single bonds are sigma bonds.

Bond strength : Single bond < Double bond < Triple bond Bond length : Single bond > Double bond > Triple bond Reactivity : Single bond < Double bond < Triple bond

20. Hybridization: The valence bond theory explains satisfactorily the formation of various molecules but fails to account the geometry and shapes of various molecules. Hybridization is a hypothetical concept. The process of mixing or amalgamation of atomic orbitals of nearly same energy to produce a set of entirely new orbitals of equivalent energy is known as hybridization.

Number of hybrid orbitals formed = number of atomic orbitals mixed

Most of the hybrid orbitals are similar but they are not necessarily identical in shape. They never form  $\pi$ -bonds.

21. Type of No. of hybrid Shape of molecule Bond angle Examples hybridization orbitals 2 Linear N<sub>2</sub>O, [Ag(CN)<sub>2</sub>]<sup>-</sup>, BeCl<sub>2</sub>, BeF<sub>2</sub>, CO<sub>2</sub>, CS<sub>2</sub>, C<sub>2</sub>H<sub>2</sub>, HgCl<sub>2</sub>, HCN sp $sp^2$ BF<sub>3</sub>, BCl<sub>3</sub>, C<sub>2</sub>H<sub>4</sub>, CO<sub>3</sub><sup>2</sup>, SO<sub>3</sub>, NO<sub>3</sub>, ČH<sub>3</sub> 3 Triangular planar  $sp^3$ CH<sub>4</sub>, CCl<sub>4</sub>, SiF<sub>4</sub>, NH<sub>4</sub>, SO<sub>4</sub><sup>2</sup> 4 **Tetrahedral** 109.5°  $dsp^2$ [PtCl<sub>4</sub>]<sup>2-</sup>, [Ni(CN)<sub>4</sub>]<sup>2-</sup> 4 Square planar 90° dsp<sup>3</sup> or sp<sup>3</sup>d 5 Trigonal bipyramidal 120° and 90° PCl<sub>5</sub>, PF<sub>5</sub>, [Fe(CO)<sub>5</sub>]  $d^2sp^3$  or  $sp^3d^2$ 6 Octahedral 90° SF<sub>6</sub>, UF<sub>6</sub>, TeF<sub>6</sub>  $d^3sp^3$  or  $sp^3d^3$ 7 Pentagonal bipyramidal 72° and 90° · IF<sub>7</sub>

Hybridization and Structures of Molecules having Lone Pair or Pairs

Type of molecule			Hybridization	Bond angle	Expected geometry	Actual geometry (shape)	Examples
AX <sub>2</sub>	2	1	$sp^2$	<120°	Trigonal	V-shaper or	SO <sub>2</sub> , SnCl <sub>2</sub> ,
					planar	Bent molecule	PbCl <sub>2</sub> , NO <sub>2</sub> <sup>+</sup>

- 22. (a) The hybridization of carbon in CH<sub>4</sub>,  $C_2H_4$  and  $C_2H_2$  is  $sp^3$ ,  $sp^2$  and sp respectively. The bond angles are 109.5°, 120° and 180° respectively.
  - (b) The hybridization of O-atom in  $H_2O$  and that of N-atom in ammonia is  $sp^3$ . The shape of  $H_2O$  is V-shape (bent molecule) while that of NH<sub>3</sub> is pyramidal. The bond angles are 104.5° and 106.5° respectively.
  - (c) The hybridization of O-atom in  $H_3O^4$  ion and that of N-atom in  $NH_4^+$  ion is  $sp^3$ . The shape of  $H_3O^+$  is pyramidal while that of  $NH_4^+$  is tetrahedral.
  - (d) The percentage of s-character in  $sp^3$ ,  $sp^2$  and sp is 25%, 33% and 50% respectively. Order of size of orbitals :  $sp < sp^2 < sp^3$ .
  - (e) Diamond involves  $sp^3$  hybridization. It is hard and a bad conductor of electricity. Graphite involves  $sp^2$  hybridization. It is soft and a good conductor of electricity.
- 23. If two or more alternate valence bond structures can be written for a molecule, the actual structure is said to be a resonance or mesomeric hybrid of all these alternate structures. Actually resonance hybrid does not oscillate between the various

mesomeric forms but it is a definite form and has a definite structure which cannot be written on paper.

Resonance hybrid has lower energy than any of contributing structures and hence is more stable. Resonating structures should have same position of atoms, same number of paired and unpaired electrons, almost equal energy. They differ only in the arrangement of electrons with a restriction that like charges should not reside on atoms closer together.

- 24. Valence shell electron pair repulsion (VSEPR): The VSEPR model developed by Gillespie and Nyholm in 1957 used for predicting the geometrical shapes of molecules is based on the assumption that electron pairs repel each other and therefore, tend to remain as far apart as possible. The molecular geometry is determined by repulsions between lone pairs and lone pairs; lone pairs and bonding pairs and bonding pairs and bonding pairs. The order of these repulsions is: lp—lp > lp—bp > bp—bp.
- 25. Molecular orbital theory of chemical bonding is more rational and more useful in comparison to valence bond theory. This theory was presented by Hund and Mullikan.

According to this theory, all the atomic orbitals of the atoms participating in molecule formation get disturbed when the concerned nuclei approach nearer. They all get mixed upto give rise to an equivalent number of new orbitals that belong to the molecule now. These are called molecular orbitals. The electrons belonging originally to participating atoms are now considered to be moving along the molecular orbitals under the influence of all the nuclei. The molecular orbitals are, thus, polycentric.

Molecular orbitals of a molecule are obtained by linear combination of atomic orbitals of the bonded atoms. When waves are combined, they may interact either constructively or destructively. When the atomic orbitals overlap in phase, constructive interaction occurs in the region between the two nuclei and a bonding orbital is produced. The energy of bonding orbital is always lower (more stable) than the energies of the combining atomic orbitals. When they overlap out of phase, destructive interference occurs and antibonding orbital is produced. The energy of antibonding orbital is higher (less stable) than the energies of the combining atomic orbitals. The filling of molecular orbitals by electrons follows aufbau principle, Hund's rule and Pauli's exclusion principle. Greek symbols,  $\sigma,\,\pi$  and  $\delta$  are used to denote the molecular orbitals.

The molecular orbitals involved in the formation of most of the molecules are:

Bonding orbitals  $\sigma$ 1s o

σ1s σ2s σ2
$$p_z$$
 π2 $p_y$  π2 $p_x$ 

Antibonding orbitals  $\mathring{\sigma}1s \, \mathring{\sigma}2s \, \mathring{\sigma}2p_z \, \mathring{\pi}2p_y \, \mathring{\pi}2p_x$ 

The sequence of molecular orbitals on the basis of energy for  $O_2$ ,  $F_2$  and  $Ne_2$  molecules is:

$$\sigma_{1s} < \dot{\sigma}_{1s} < \sigma_{2s} < \dot{\sigma}_{2s} < \sigma_{2p_z} < \frac{\pi^2 p_y}{\pi^2 p_x} < \frac{\pi^2 p_y}{\pi^2 p_x} < \pi^2 p_z$$

and the sequence of molecular orbitals for  $B_2$ ,  $C_2$ ,  $N_2$  molecules is:

$$\sigma 1s < \dot{\sigma} 1s < \sigma 2s < \dot{\sigma} 2s < \frac{\pi}{\pi} 2 p_y < \sigma 2 p_z < \frac{\pi}{\pi} 2 p_y < \dot{\sigma} 2 p_z$$

The maximum number of electrons which can be accommodated in a molecular orbital is two. If there are two molecular orbitals having same energy, the electrons will first enter these singly and both of them have achieved one electron each, pairing will start.

A molecule is formed only when the total energy of the system decreases. This is only possible when the bonding electrons are more than antibonding electrons.

The number of covalent bonds in a molecule is indicated by bond order.

Bond order =

- (a) Greater the bond order of a diatomic molecule or ion, the more stable it will be.
- (b) Greater bond energy indicates the greater stability of the bond.
- (c) Fractional bond order indicates ion.
- (d) Negative bond order is impossible. It rather indicates instability. The species does not exist.
- (e) Zero bond order also indicates that species does not exist.26. According to 'electron sea model' of metallic bond, metal

consists of positively charged ions called kernels in a sea of mobile electrons. The metallic bond is formed due to simultaneous attraction of mobile electrons by the kernels. According to 'valence bond model' or 'resonance model' the covalent bond present between metal atoms resonates among the neighbouring metal atoms.

According to 'bond model' or 'molecular orbital approach' atomic orbitals merge to form energy bonds. A substance is a conductor when the electrons can be readily promoted to the conduction band where they are free to move through the substance. In insulators, the energy gap between the valence band and the conduction band is so large that the electrons cannot be promoted to the conduction band. In semiconductors, electrons can cross the energy gap at high temperatures.

- (a) Isoelectronic species have the same shape and same bond order.
  - (b) The *d*-orbital taking part in  $dsp^2$  hybridization is  $d_{x^2-y^2}$ , in  $sp^3d$  hybridization it is  $d_{z^2}$  and in  $sp^3d^2$ , the two *d*-orbitals involved are  $d_{x^2-y^2}$  and  $d_{z^2}$ . In  $sp^3d^3$  hybridization, the *d*-orbitals involved are  $d_{xy}$ ,  $d_{yz}$  and  $d_{xz}$ .
  - (c) The bond lengths of O2 and its ions are in the order

$$O_2^{2-} > O_2^- > O_2 > O_2^+$$

as their bond orders are 1, 1.5, 2 and 2.5 respectively.

Bond length 
$$\propto \frac{1}{\text{bond order}}$$

- (d) H-atom always forms sigma bond.
- (e) As the s-character increases in hybridized orbitals, the size becomes smaller of the hybridized orbitals. The bond length decreases while bond energy increases.
- (f) Isosteres are molecules containing same number of atoms and electrons. For example, CO and N<sub>2</sub>.
- (g) There are a number of stable molecules in which the bonds are formed by sharing of an odd number of electrons. Such type of bonds are called odd electron bonds. Some common examples are:

- (h) Electrovalent bonding is strongest while hydrogen bonding is weakest.
- (i) The stability of N<sub>2</sub> and its ions is in the order

$$N_2 > N_2^+ = N_2^- > N_2^{2-}$$

as their bond orders are 3, 2.5, 2.5 and 2 respectively.

(j) Out of  $O_2$ ,  $O_2^+$ ,  $O_2^-$  and  $O_2^{2-}$ , the diamagnetic species is  $O_2^{2-}$ .

## PRACTICE PROBLEM

## **■** Subjective Type Questions

- 1. (a) Write Lewis dot symbols for the following atoms and ions:
  - (i) S and S<sup>2-</sup>
- (ii) Al and Al<sup>3+</sup>
- (iii) Br and Br
- (iv) O and O<sup>2-</sup>
- (v) Sr and  $Sr^{2+}$
- (b) Draw Lewis structures for the following ionic compounds:
  - (i) MgS (ii) AlN
- (iii) CaBr<sub>2</sub> (a) Which one has higher lattice energy?

NaCl or CsCl

- (b) How is lattice energy related with stability of an ionic compound?
- (c) Why are MgO, Al<sub>2</sub>O<sub>3</sub>, etc., used as refractory materials?
- Assign formal charges to each atom in the following structures. Based on formal charges, which is the preferred Lewis structure for the molecule, the dinitrogen monoxide?
  - (a) N = N = 0
- (b) : N = N O:
- (a) Identify the compounds in the following in which S does not obey octet rule.

SO<sub>2</sub>, SF<sub>2</sub>, SF<sub>4</sub>, SF<sub>6</sub>

- (b) Arrange the following in increasing order of dipole moment.
  - (i) CH<sub>3</sub>I, CH<sub>3</sub>Br, CH<sub>3</sub>F, CH<sub>3</sub>Cl
  - (ii) BF<sub>3</sub>, H<sub>2</sub>S, H<sub>2</sub>O
- 5. (a) State whether the following are ionic or covalent:
  - (ii) SnCl<sub>4</sub> (iii) diamond (iv) CaC<sub>2</sub> (i) Na<sub>2</sub>S
  - (v) NaH (vi) C<sub>2</sub>H<sub>4</sub> (vii) CaCl<sub>2</sub> (viii) HCl gas
  - (ix) NH<sub>4</sub> (x) KBr
  - (b) Indicate whether the following pairs of elements form ionic or covalent compounds and write down the molecular formula of the compound formed.
    - (i) sodium and chlorine (ii) carbon and sulphur
    - (iii) sulphur and oxygen (iv) calcium and hydrogen
  - (c) What type of bonds are present in the following molecules?
    - (i) MgF<sub>2</sub> (ii) BrCl (iii) CBr<sub>4</sub> (iv) C<sub>2</sub>N<sub>2</sub> (v) CuS
    - (vi) H<sub>2</sub>O (vii) H<sub>2</sub>SO<sub>4</sub>
- (viii) SO<sub>2</sub> (ix) HNO<sub>3</sub>
- (x)  $K_4Fe(CN)_6$
- (d) What type of chemical bond is formed between two atoms when:
  - (i) electronegativity difference is zero.
  - (ii) electronegativity difference is small.
  - (iii) electronegativity difference is high.
- 6. (i) Among the following,
  - NaCl, CCl<sub>4</sub>, HCl and CH<sub>4</sub> which is a polar compound?
  - (ii) Which among the following,
    - H<sub>2</sub>O, NH<sub>3</sub>, BF<sub>3</sub> and NH<sub>4</sub> possesses a coordinate bond?
  - (iii) Among the compounds CH<sub>3</sub>COOH, NH<sub>3</sub>, HF and CH<sub>4</sub> in which maximum hydrogen bonding is present?

- (iv) Amongst LiF and LiI which has more covalent character?
- (v) Amongst o-hydroxybenzaldehyde and p-hydroxybenzaldehyde which is more soluble in water?
- (vi) Which among the following have highest lattice energy?

NaCl, KCl, CsCl

(vii) Which one of the following is non-polar?

SO<sub>2</sub>, CHCl<sub>3</sub>, CO<sub>2</sub>, H<sub>2</sub>O, NH<sub>3</sub>

(viii) Which one of the following has strongest bond?

HF, HCl, HBr, HI

- 7. Arrange the following in each as instructed:
  - (i) O, F, S, Cl, N in order of increasing strength of hydrogen bonding (X - - - H - X). [M.L.N.R. 1993]
  - (ii) N2, O2, F2, Cl2 in increasing order of bond dissociation energy.
  - (iii) NO<sub>2</sub>, NO<sub>2</sub>, NO<sub>3</sub> in order of increasing N—O bond length. [M.L.N.R. 1993]
  - (iv) C—C, C=C, C≡C in order of increasing bond energy.
  - (v) C—C, C=C, C≡C in order of increasing bond length.
  - (vi) PH<sub>3</sub>, AsH<sub>3</sub>, SbH<sub>3</sub>, NH<sub>3</sub> in order of increasing polarity.
  - (vii) H2O, NH3, CH4, SF6, BF3, CO2 in order of increasing bond angle.
  - (viii) MgO, CaO, SrO, BaO in order of increasing lattice energy.
  - (ix) Arrange the following in order of increasing bond order,

 $N_2$ ,  $F_2$ ,  $O_2$ ,  $O_2^-$ ,  $O_2^+$ 

- (x) NO, NO<sup>+</sup> and NO<sup>-</sup> in increasing order of bond length.
- Answer the following:
  - (i) How many electron pairs are shared in N2 molecule?
  - (ii) What is the valency of carbon in  $C_2H_4$  and  $C_2H_2$ ?
  - (iii) Which hybridization is predicted for P in PF5 and S in SF<sub>6</sub>?
  - (iv) What types of bonds and how many of each are present in NH<sub>4</sub>?
  - (v) Which hybridization is predicted for Cl in ClF<sub>3</sub>?
  - (vi) Why the bond angle in H<sub>2</sub>O is greater than 90°?
  - (vii) What is the shape of acetylene molecule?
  - (viii) Why zero group elements are inert in nature?
    - (ix) Which type of elements can form electrovalent bond?
    - (x) What type of bond is formed by sharing an electron pair?
  - (xi) Which type of bond exists in molecule NO?
  - (xii) What type of hydrogen bonding exists in liquid water?
  - (xiii) What type of hydrogen bonding exists in orthochlorophenol?
  - (xiv) How many orbitals are singly occupied in O2 molecule?
  - (xv) Why Neon molecule (Ne<sub>2</sub>) is not possible?
  - (xvi) What is magnetic nature of  $O_2^{2-}$  species?

- 9. (a) Two elements *A* and *B* combine to form a compound *AB*. Under what conditions the bond formed will be electrovalent?
  - (b) Two elements A and B combine to form a compound AB. Under what conditions the compound formed will be covalent?
  - (c) Two elements *A* and *B* participate by sharing electrons in chemical bonding. *B* does not contribute any electron of its own. What type of bond is formed?
  - (d) Atoms A, B and C occur in same period and have one, six and seven valence electrons respectively.
    - (i) Will the bond between *B* and *C* predominently ionic or covalent? Explain.
    - (ii) Write the electronic structure of the compound formed between B and C.
    - (iii) Will the bond between *A* and *B* predominently ionic or covalent? Explain.
  - (e) Three elements A, B and C have atomic numbers Z–2, Z and Z+1 respectively. Of these, B is an inert gas.
    - (i) Which one has the highest value of electronegativity?
    - (ii) Which one has the highest value of ionisation potential?
    - (iii) What is formula of compound between A and C?
    - (iv) What will be the nature of the bond between *A* and *C* in the compound formed ?
- 10. (i) Write the two resonance structures of ozone which satisfy the octet rule. [I.I.T 1991]
  - (ii) Write the two resonance structures of  $N_2O$  that satisfy the octet rule. [I.I.T 1990]
  - (iii) Write the resonance structures of carbonate ion.
  - (iv) Write the resonance structures of  $N_3$  ion.
  - (v) Write the resonance structures of NO<sub>3</sub> ion.
  - (vi) Write the resonance structures of SO<sub>4</sub><sup>2</sup>-ion.
- 11. Write down the Lewis formula or electron dot formula of the following compounds:
  - (a) (i)  $SiCl_4$  (ii)  $CO_2$  (iii)  $PO_4^3$  (iv)  $H_2O_2$
  - (b) (i)  $O_3$  (ii)  $COCl_2$  (iii)  $N_2O_5$  (iv)  $S_2O_3^2$ 
    - (v)  $ClO_3^-$  (vi) CO (vii)  $SO_2Cl_2$  (viii)  $P_2O_7^4$
    - (ix)  $N_2O_4$  (x)  $NH_4^+$
- **12.** Write down the hybridization of the central atom and geometry of the following molecules or ions:
  - (a)  $I_3^-$  (b)  $PbCl_4$  (c)  $ICl_4^-$  (d)  $XeF_4$  (e)  $BH_4^-$
  - (f) ClF<sub>3</sub> (g) HOCl.
- **13.** (a) Which of the following species has greater polarising power?
  - (i)  $Fe^{3+}$  or  $Fe^{2+}$  (ii)  $Cu^{+}$  or  $Na^{+}$  (iii)  $Mg^{2+}$  or  $Al^{3+}$
  - (b) Which of the following species will be most susceptible to polarisation?
    - (i)  $Br^-$  or  $I^-$  (ii)  $O^{2-}$  or  $S^{2-}$  (iii)  $N^{3-}$  or  $O^{2-}$
  - (c) Which compound of each of the following pairs is more covalent?
    - (i) CuO or CuS
- (ii) AgCl or AgI

- (iii) PbCl2 or PbCl4
- (iv) AlCl3 or GaCl3
- (v) LiCl or KCl
- (vi) BeCl2 or MgCl2
- (d) Which of the following pairs of bonds contain the larger ionic contribution to the bonding?
  - (i)  $K^+-F^-$  or  $K^+-I^-$  (ii)  $Na^+-O^{2-}$  or  $Mg^{2+}-O^{2-}$
- (e) Which of the following species has higher melting point?
  - (i) NaCl or CuCl
- (ii) CaF<sub>2</sub> or CaI<sub>2</sub>
- (iii) CaCl<sub>2</sub> or CdCl<sub>2</sub>
- 14. (a) What type of bond is normally expected between:
  - (i) a small cation and large anion.
  - (ii) two electronegative atoms.
  - (iii) a highly electropositive and highly electronegative atoms.
  - (iv) an atom with a completed octet and an atom with a sextet of electrons?
  - (b) Give one example of each:
    - (i) A molecule with central atom devoid of octet.
    - (ii) A molecule with linear shape.
    - (iii) An ionic compound insoluble in water.
    - (iv) Almost a non-polar covalent compound between two different atoms.
    - (v) A stable compound formed by combination of two stable compounds through coordination.
    - (vi) A compound which is bad conductor in gaseous state but its aqueous solution is a good conductor of current.
    - (vii) A compound whose central atom undergoes  $sp^3$  hybridization possesses bond angle about 106.5°.
  - (c) (i) Which one of them is more ionic and why? LiC.
    NaCl
    - (ii) Which one of them is having higher melting point and why? AlCl<sub>3</sub>, MgCl<sub>2</sub>
    - (iii) Which one of them is a good conductor of electricity and why? NaCl, CH<sub>4</sub>
    - (iv) Which one of them is pyramidal and why? BCl<sub>3</sub>, NH<sub>3</sub>
    - (v) Which one of them is a liquid and why? HF, H<sub>2</sub>S
- 15. Explain with suitable examples or write short notes on:
  - (i) Electrovalency
- (ix) Octet rule
- (ii) Covalency
- (x) Dipole moment
- (iii) Coordinate valency(iv) Hydrogen bonding
- (xi) Hybridization(xii) Fajan's rules
- (v) Metallic bonding
- (xiii) Sigma and  $\pi$ -bonds
- (vi) Variable valency
- (xiv) Bond order
- (vii) Inert pair effect
- (xv) Lattice energy
- (viii) Resonance
- (xvi) Polar and non-polar bonds
- 16. Give reasons for the following:
  - (i) The boiling point of ethyl alcohol is much higher than that of diethyl ether.
    - [Hint: Hydrogen bonding is present in alcohol. It is an associated liquid. No hydrogen bonding is present in diethyl ether.]
  - (ii) BCl<sub>3</sub> and BF<sub>3</sub> are non-polar.
    - [Hint: Both are triangular planar and symmetrical molecules. Their dipole moments are zero.]

(iii) Water is good solvent for ionic compounds.

[Hint: Water has high dielectric constant and polar in nature. These properties help in the ionisation of ionic compounds.]

(iv) MgCl<sub>2</sub> is linear but SnCl<sub>2</sub> is angular.

[M.L.N.R. 1995]

[Hint: In MgCl2, Mg is sp hybridized while in SnCl2, Sn is sp<sup>2</sup> hybridized.]

(v) NCl<sub>5</sub> does not exist while PCl<sub>5</sub> does.

[Hint: In N-atom d-orbitals are not present while in P-atom d-orbitals are present and ns electron can be shifted to nd-orbital.]

(vi) Lead prefers to form divalent compounds.

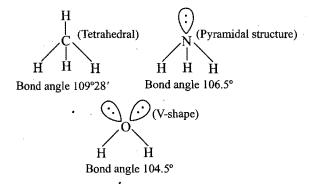

[Hint: ns2 pair of electrons inert and only two electrons of np-orbitals participate. This is due to inner penetration of ns-orbital.]

(vii) Sigma bond is more stronger than  $\pi$ -bond.

[Hint: In sigma bond greater overlapping takes place.]

(viii) CH<sub>4</sub>, NH<sub>3</sub> and H<sub>2</sub>O contain same number of electrons but their shapes are different.

[Hint: The central atom in each of the three molecules CH4, NH<sub>3</sub> and H<sub>2</sub>O undergoes sp<sup>3</sup> hybridization. In CH<sub>4</sub>, no lone pair is present. In NH3 one lone pair is present while in water two lone pairs are present.]

(ix) Calcium fluoride is more ionic than Cal<sub>2</sub>.

[Hint: The size of I ion is bigger than F ions. In CaI2, therefore, more polarisation is present. Thus, CaF2 is more ionic than Cal2.]

(x) Ammonium salts are much more soluble in water than the corresponding sodium salts.

[Hint: Na+ ion is solvated by ion-dipole interaction while NH<sub>4</sub> ion is solvated by H-bonding which is a stronger attractive force.]

(xi) Carbon has two electrons in the outermost, but it is tetravalent in organic compounds.

[Hint: Since, all the four valencies of carbon are identical, 2s electron is shifted to one of the vacant p-orbital with the result four unpaired orbitals are present. These undergo hybridization and form four hybrid

(xii) Why BeF<sub>2</sub> and BF<sub>3</sub> are stable though Be and B have less than 8 electrons? Which one is more stable?

[Hint: The stability is explained by symmetrical linear structure for BeF2 and triangular planar structure for BF3. BeF2 is more stable because of its greater bond angle (180°).]

(xiii) Though the electronegativities of nitrogen and chlorine are same, NH3 exists as liquid whereas HCl as gas. Why?

[Hint: The size of nitrogen is less than the size of chlorine. Therefore, electron density in nitrogen is more than that of chlorine. So, nitrogen forms hydrogen bonding leading to association of molecules. Hence, NH3 is a liquid. Hydrogen bonding is not possible with chlorine.]

(xiv) Why the repulsions between non-bonded orbitals are greater than between the bonded orbitals?

[Hint: The non-bonded orbitals relatively occupy more space compared to the bonded orbitals and thus repulsions are greater.]

(xv) Although CO2 has no dipole moment, SO2 and H2O have considerable dipole moments.

[Hint: CO2 has linear structure while SO2 and H2O have V-shaped structures.]

Dipole moments

(xvi) Nitrogen trifluoride (NF3) and ammonia (NH3) have identical shape and a lone pair of electrons on nitrogen and further the electronegativity difference between the elements is nearly the same but the dipole moment of NH<sub>3</sub> is very high in comparison to NF<sub>3</sub>.

> [Hint: It is due to different directions of moments of the N-H and N-F bonds.]

(xvii) Although formation of NH3 and H2O molecules involve  $sp^3$  hybridization, their bond angles are shorter than the normal tetrahedral angle.

> [Hint: This is due to the presence of one lone pair of electrons on nitrogen atom in NH3 and two lone pairs of electrons on oxygen atom in H2O.]

(xviii) Bond order in N2 is 3 whereas it is 2.5 in NO.

[M.L.N.R. 1994]

[Hint:  $N_2 = (\sigma 1s)^2 (\tilde{\sigma} 1s)^2 (\sigma 2s)^2 (\tilde{\sigma} 2s)^2 (\sigma 2p_x)^2 (\pi 2p_y)^2 (\pi 2p_z)^2$ 

Bond order = 
$$\frac{1}{2}(10 - 4) = 3$$

NO =  $(\sigma 1s)^2 (\overset{*}{\sigma} 1s)^2 (\sigma 2s)^2 (\sigma 2s)^2 (\sigma 2p_x)^2 (\pi 2p_y)^2 (\pi 2p_z)^2 (\overset{*}{\pi} 2p_y)^1$ 

**Bond** order = 
$$\frac{1}{2}(10 - 5) = 2.5$$
]

- (xix) Three carbon-oxygen bonds are equal in carbonate ion. [Hint: The carbonate ion exhibits resonance and therefore, all the three C-O bonds are equal.]
- (xx) Valency of oxygen is generally two whereas sulphur shows valency of two, four and six.

[Hint: There are no d-orbitals in oxygen hence it cannot extend its covalency. Vacant d-orbitals are present in sulphur and paired orbitals can be unpaired by shifting electrons to d-orbitals, i.e., either making four orbitals singly occupied or six orbitals singly occupied showing valency 4 or 6 besides 2.]

(xxi) SnCl<sub>2</sub> is ionic but SnCl<sub>4</sub> is covalent.

[Hint: The size of Sn<sup>4+</sup> ion is smaller than Sn<sup>2+</sup> ion. Hence, polarisation or distortion is more in SnCl<sub>4</sub>, so, it is covalent.]

(xxii) NF<sub>3</sub> is weaker base than NH<sub>3</sub>, NCl<sub>3</sub>, NBr<sub>3</sub> and NI<sub>3</sub>.
[Hint: It is due to larger electronegativity of F-atoms of NF<sub>3</sub>. The lone pair is most difficult to be donated.

(xxiii) BaSO<sub>4</sub> is insoluble in water.

[Hint: Lattice energy is more than hydration energy.]

(xxiv) NO molecule is paramagnetic.

[**Hint**: The molecule contains one unpaired electron in its three electron bond.]

(xxv) Compounds of normal elements are diamagnetic.

[Hint: Normal elements acquire inert gas configuration in compounds, i.e., all the orbitals are doubly occupied and thus, compounds are diamagnetic.]

(xxvi) Anhydrous HCl is bad conductor but in aqueous medium, it is good conductor of current.

[Hint: HCl is a covalent compound and in gaseous state, it does not conduct current. In water, however it reacts to form ions, HCl + H<sub>2</sub>O 

→ H<sub>3</sub>O<sup>+</sup> + Cl<sup>-</sup> and thus conducts current.]

(xxvii) A bond order of 3 is computed for the diatomic molecule. It is possible that in the absence of further information, this triple bond may be made up of two σ-and one π-bonds. Explain.

[Hint: Not possible. The order of filling orbitals and the differentiations existing among bonding, antibonding and non-bonding electrons, never permit the establishing more than one sigma bond.]

(xxviii) Diamond is a hard solid with a very high melting point but a non-conductor of electricity.

[**Hint**: Diamond is a giant molecule–three dimensional figure as every carbon is  $sp^3$  hybridized, *i.e.*, one carbon atom is linked to four other carbon atoms tetrahedrally. Due to continuous covalent bonding all the atoms are held very closely and strongly. As a result, diamond is a very hard solid with high melting point. It is bad conductor as free electrons are not available.]

(xxix) AlCl<sub>3</sub> is largely covalent while AlF<sub>3</sub> is largely ionic. [M.L.N.R. 1995]

[Hint: Due to larger size of Cl<sup>-</sup> ion than F<sup>-</sup> ion, there is greater degree of distortion in AlCl<sub>3</sub>.]

#### 17. Give reasons for the following:

(a) Carbon-oxygen bond lengths in Na<sub>2</sub>CO<sub>3</sub> are equal. [Hint: Bond lengths are equal due to resonance in carbonate ion.]

(b) BeCl<sub>2</sub> has zero dipole moment while SnCl<sub>2</sub> has a dipole moment.

[**Hint**: BeCl<sub>2</sub> has a linear structure while SnCl<sub>2</sub> has angular shape.]

(c) Among planar structures, why the linear structure is more stable than trigonal and square planar?

[Hint: Among planar structures, stability increases with an increase in the bond angle. The bond angle is maximum (180°) in linear structure.]

(d) Why do cotton clothes take a long time to dry as compared to synthetic clothes.

[Hint: Cotton fibres form hydrogen bonds with water molecules.]

(e) Benzene molecule is stable inspite of the fact that it consists of three double bond.

[Hint: Resonance exists in benzene molecule.]

18. Dipole moment of KCl is 3.336 × 10<sup>-29</sup> coulomb metre which indicates that it is highly polar molecule. The interatomic distance between K<sup>+</sup> and Cl<sup>-</sup> in this molecule is 2.6 × 10<sup>-10</sup> m. Calculate the dipole moment of KCl molecule if there were opposite charges of one fundamental unit located at each molecule. Calculate the percentage of ionic character of KCl.

[Ans.  $4.1652 \times 10^{-29}$  coulomb metre, percentage of ionic character = 80.09]

- 19. The dipole moment of HBr is 2.60 × 10<sup>-30</sup> cm and the interatomic spacing is 1.41 Å. What is the percentage ionic character of HBr?
  [Ans. 11.5%]
- 20. Calculate the percentage of ionic character in K—Cl bond in KCl molecule. The electronegativity values of K and ·Cl are 0.8 and 3.0 respectively.[Ans. 52.1%]
- 21. Calculate the lattice enthalpy of LiF give that the enthalpy of (i) Sublimation of lithium is 155.2 kJ mol<sup>-1</sup>; (ii) Dissociation of 1/2 mole of F<sub>2</sub> is 75.3 kJ; (iii) Ionization energy of lithium is 520 kJ mol<sup>-1</sup>; (iv) Electron gain enthalpy of F(g) is -333 kJ mol<sup>-1</sup>; (v) ΔH<sub>f</sub>° overall is -594.1 kJ mol<sup>-1</sup>.
  [Ans. 1011.6 kJ mol<sup>-1</sup>]

## ■ Matching Type Questions

## Auswers

#### Answers: Subjective Type Questions

1. (a) (i) 
$$:\dot{S}:$$
 and  $\left[:\dot{S}:\right]^{2-}$  (ii)  $:\dot{A}!$  and  $\left[Al\right]^{3+}$  (iii)  $:\dot{B}$  and  $\left[:\dot{B}$ :  $:\dot{C}:$  (iv)  $:\dot{C}:$  and  $:\dot{C}:$   $:\dot{C}:$ 

(b) (i) 
$$Mg$$
 : or  $[Mg]^{2+}$  [:  $x = 1$ ]  $x = 1$ ]

(ii) 
$$\stackrel{\times}{\text{Al}} \stackrel{\times}{\text{N}} \stackrel{\circ}{\text{N}} = \text{Or} \quad [\text{Al}]^{3+} \left[ \stackrel{\times}{\text{N}} \stackrel{\circ}{\text{N}} \stackrel{\circ}{\text{N}} \right]^{3}$$

(iii) 
$$\overset{\times}{\text{Ca}}$$
 Br. or  $[\text{Ca}]^{2^+}$  2  $[\overset{\times}{\text{Br}}$   $]^-$ 

- 2. (a) NaCl as Na+ ion is smaller in size than Cs+ ion.
  - (b) Stability is dependent on the magnitude of lattice energy. High negative value of lattice energy gives more stability to an ionic compound.
  - (c) MgO and Al<sub>2</sub>O<sub>3</sub> are used as refractory materials because they have high melting points on account of high lattice energies.
- 3. (a) From left to right -1, +1, 0
  - (b) From left to right 0, +1, -1

Thus, structure (b) is preferred as negative charge is present on more electronegative atom.

- 4. (a)  $SF_4$  and  $SF_6$ 
  - (b) (i)  $CH_3I < CH_3Br < CH_3CI < CH_3F$ (ii)  $BF_3 < H_2S < H_2O$
- 5. (a) Ionic Na<sub>2</sub>S, NaH, CaCl<sub>2</sub>, KBr, CaC<sub>2</sub> (However covalent bonding exists between carbon atoms.)

Covalent SnCl<sub>4</sub>, diamond, C<sub>2</sub>H<sub>4</sub>, HCl (gas), NH<sup>+</sup><sub>4</sub>

- (b) (i) Ionic NaCl, (ii) Covalent  $CS_2$ , (iii) Covalent  $SO_2$  and  $SO_3$ , (iv) Ionic  $CaH_2$ .
- (c) (i) Ionic, (ii) Covalent, (iii) Covalent, (iv) Covalent, (v) Ionic, (vi) Covalent, (vii) Covalent and coordinate, (viii) Covalent and coordinate, (ix) Covalent and coordinate, (x) Electrovalent and coordinate. (d) (i) Pure covalent bond, (ii) Semipolar bond, (iii) Electrovalent.
- 6. (i) NaCl is the polar compound as the electronegativity difference is maximum, (ii) NH¼ [NH₃→H]⁺, (iii) HF (electronegativity of fluorine is maximum), (iv) The size of I⁻ ion is larger than F⁻ ion. Hence, more of polarisation by Li⁺ ion in LiI occurs. Thus, LiI is more covalent, (v) p-hydroxybenzaldehyde is more soluble in water as it forms hydrogen bonding with water, (vi) NaCl. Charges are same on the ions but size of Na⁺ ion is smaller than K⁺ and Cs⁺ ions, (vii) CO₂ is a non-polar molecule as it has symmetrical shape, (viii) HF.
- 7. (i) Strength of hydrogen bonding depends on electronegativity of atom linked with hydrogen. Thus, the order is S < Cl < N < O < F (ii) The increasing order is  $F_2 < Cl_2 < O_2 < N_2$ . Both fluorine and chlorine atoms in  $F_2$  and  $Cl_2$  possess three non-bonded electron pairs each. Due to small size of fluorine, there is larger repulsion between non-bonded electrons in comparison to chlorine. Thus,  $F_2$  has lesser dissociation energy than  $Cl_2$ . In oxygen,

two non-bonded electron pairs are present, *i.e.*, less repulsion than  $\text{Cl}_2$  and in nitrogen only one electron pair is present, *i.e.*, minimum repulsion is present. Hence,  $\text{N}_2$  has maximum stability.

(iii)  $NO_2^+ < NO_2^- < NO_3^-$ 

(iv) C-C < C=C < C=C

(Energy increases with multiplicity.)

(v) C≡C < C=C < C-C

(Bond length decreases with multiplicity.)

(vi) Polarity can be decided on electronegativity difference.

$$PH_3 < AsH_3 < SbH_3 < NH_3$$

(viii) BaO < SrO < CaO < MgO

[Hint: Size of cation in decreasing order.]

(ix) 
$$F_2 < O_2^- < O_2 < O_2^+ < N_2$$
  
Bond order 1 1.5 2.0 2.5 3.0  
(x)  $NO^+ < NO < NO^-$ 

Bond order 3 2.5 2

Higher the bond order, smaller is the bond length.

- 8. (i) three; (ii) four; (iii)  $sp^3d$ ,  $sp^3d^2$ ; (iv) three covalent and one coordinate; (v)  $sp^3d$  (bonding pairs + lone pairs = 5); (vi)  $sp^3$  hybridization of oxygen; (vii) linear (both carbon atoms are sp hybridized); (viii) possess stable electronic configuration; (ix) highly electropositive and highly electronegative; (x) covalent; (xi) odd electron; (xii) interhydrogen bonding; (xiii) intrahydrogen bonding; (xiv) two; (xv) bond order—zero; (xvi) diamagnetic.
- 9. (a) If the electronegativity difference is more than 1.7;
  - (b) If the electronegativity difference is less than 1.7;
  - (c) Coordinate bond; (d) (i) covalent, electronegativity difference

10. (i) 
$$O^{+}$$
  $O^{+}$   $O^{+$ 

12. (a)  $sp^3d$ , linear; (b)  $sp^3$ , tetrahedral; (c)  $sp^3d^2$ , square planar; (d)  $sp^3d^2$ , square planar (similar to c); (e) tetrahedral,  $sp^3$ ;

-F; (g) oxygen undergoes sp<sup>3</sup>

hybridization, V-shape structure.

- 13. (a) (i) Fe<sup>3+</sup>
- (iii) Al3+

- (b) (i) I<sup>-</sup>
- (ii) S<sup>2-</sup>
- (iii) N<sup>3-</sup>
- (c) (i) CuS (ii) AgI (iii)  $PbCl_4$  (iv)  $AlCl_3$  (v) LiCl (vi)  $BeCl_2$
- (d) (i) K<sup>+</sup>—F<sup>-</sup> (ii) Na<sup>+</sup>—O<sup>2</sup>-
- (e) (i) NaCl (ii) CaF2 (iii) CaCl2
- 14. (a) (i) Ionic bond with partial covalent character, (ii) covalent, (iii) ionic, (iv) coordinate.
  - (b) (i)  $BF_3$ , (ii)  $BeCl_2$  or  $CO_2$ , (iii)  $BaSO_4$ , (iv)  $CH_4$ ,
  - (v)  $NH_4Cl[(H_3N\rightarrow H)^+Cl^-]$  or  $(H_3N\rightarrow BF_3)$ , (vi) HCl, (vii)  $NH_3$ .
  - (c) (i) NaCl (very small distortion).
  - (ii) MgCl<sub>2</sub> (more ionic than AlCl<sub>3</sub>).
  - (iii) NaCl in molten state (as ions are present in mobile state).
  - (iv)  $NH_{3}$ ,  $(sp^3$  hybridization. One lone pair is present on N-atom).
  - (v) HF (Hydrogen bonding is present. Molecules come nearer to each other and associate through hydrogen bonds).

#### **Answers**: Matching Type Questions

- (A) (a-iv); (b-i); (c-v); (d-ii); (e-iii); (f-vi)
- (B) (1-v-b); (2-vi-d); (3-i-c); (4-ii-f); (5-iii-a); (6-iv-e)
- (C) (a-viii); (b-x); (c-ix); (d-ii); (e-i); (f-vii); (g-iii); (h-v); (i-iv); (j-vi)

# ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. The electronegativity of H and Cl are 2.1 and 3.0 respectively. The correct statement(s) about the nature of HCl is/are:
  - (a) HCl is 17% ionic
- (b) 83% ionic

(c) 50%

(d) 100%

Ans. (a)

[Hint: % ionic character = 
$$16 (X_A - X_B) + 3.5 (X_A - X_B)^2$$
  
=  $16 (3.0 - 2.1) + 3.5 (3.0 - 2.1)^2$   
=  $14.4 + 2.835 = 17.235 \approx 17\%$ ]

- The order of strength of hydrogen bond is:
  - (a) Cl—H....Cl > N—H....N > O—H....O > F—H....F
  - (b) N-H....N > Cl-H....Cl > O-H....O > F-H....F
  - (c) O-H....O > N-H....N > Cl-H....Cl > F-H....F
  - (d) F-H....F > O-H....O > N-H....N > Cl-H....Cl

[Hint: Hydrogen bond strength increases with the increase of electronegativity and decrease in size of the atom.

Electronegativity =  $F > O > N \approx Cl$ 

- The electronegativity of O, F, N, Cl and H are 3.5, 4.0, 3.2, 3.0 and 2.1 respectively. The strongest bond will be:
  - (a) F-O Ans. (d)
- (b) O—Cl
- (c) N—H

[Hint: Bond strength 

difference in electronegativity of atoms.]

- The carbonyl group has following resonating structures:
  - $(I) > \tilde{C} \tilde{O}$
- (II) > C̄—Ō
- (III) > C = O

The correct order of stability of these structures is :

- (a) I > II > III
- (b) III > I > II
- (c) I > III > II
- (d) III > II > I

Ans. (b)

- IHint: The resonating structure with minimum or no charge is more stable. Thus, the stability of (III) form is maximum. The structure (I) is more stable than structure (II) as the negative charge is present on more electronegative atom.]
- Which combination will give the strongest ionic bond?
  - (a) Na<sup>+</sup> and Cl<sup>-</sup>
- (b) Mg<sup>2+</sup> and Cl<sup>-</sup>
- (c)  $Na^+$  and  $O^{2-}$
- (d)  $Mg^{2+}$  and  $O^{2-}$

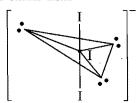

Ans. (d)

[Hint: Ionic bond strength depends on the force of attraction between cation and anion.  $F \propto \frac{q_1 q_2}{r^2}$ 

- 6. Number of bonding pairs and lone pairs around the central atom in the  $I_3^-$  ion are:
  - (a) 2, 2
- (b) 3, 2
- (c) 2, 3
- (d) 4, 3

Ans. (c)

[Hint: There are two bonding pairs and three lone pairs in the outershell of central atom.

- 7. The formal charge on the central oxygen atom in O<sub>3</sub> molecule is:
  - (a) 0

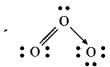

(b) + 1

(c) -1

(d) - 2

Ans. (b)

[Hint: The Lewis dot structure of O3 is:

Formal charge on central oxygen atom = Valence electrons -

½ bonding electrons - non-bonding electrons

$$= 6 - \frac{1}{2} \times 6 - 2 = + 1$$

8. Match List I (species) and List II (bond orders) and select the correct answer:

the correct answer:							
	List I				List II		
A.	$N_2$			1.	1.0		
B.	$O_2$		•	2.	2.0		
C.	$F_2$			3.	2.5		
D.	$O_2^+$			4.	3.0		
	Α	В	C	D			
(a)	4	2	1	3			
(b)	1	3	4	2			
(c)	1	2	4	3			
(d)	4	3	1	2			
Anc	(2)						

**[Hint:**  $N_2 : \sigma(2s)^2 \dot{\sigma}(2s)^2 \pi (2p_x)^2 \pi (2p_y)^2 \sigma (2p_z)^2$ ;

Bond order = 
$$\frac{1}{2}(8-2) = 3$$

 ${\rm O}_2 \,:\, ({\rm G2}s)^2 \,({\rm \mathring{c}2}s)^2 \,({\rm G2}p_z)^2 (\pi_u 2p_u)^2 (\pi_z 2p_x)^2 \,({\rm \mathring{\pi}}_u 2p_u)^1 ({\rm \mathring{\pi}}_z 2p_x)^1;$ 

Bond order = 
$$\frac{1}{2}(8-4) = 2$$

 $F_2: (\sigma 2s)^2 (\mathring{\sigma} 2s)^2 (\sigma 2p_z)^2 (\pi_u 2p_u)^2 (\pi_z 2p_x)^2 (\mathring{\pi}_u 2p_u)^2 (\mathring{\pi}_z 2p_x)^2;$ 

Bond order = 
$$\frac{1}{2}(8-6) = 1$$

 $O_2^+: (\sigma 2s)^2 (\mathring{\sigma} 2s)^2 (\sigma 2p_z)^2 (\pi_y 2p_y)^2 (\pi_z 2p_x)^2 (\mathring{\pi}_y 2p_y)^1;$ 

Bond order = 
$$\frac{1}{2}(8-3) = 2.5$$
]

- 9. Which of the following have identical bond order?
  - (I) CN⁻ (II) O⁻₂ (III) NO⁺ (IV) CN⁺
  - (a) I, III

- (c) II, IV
- (d) I, II, III

Ans. (a)

[Hint: Isoelectronic species have same bond order.

$$CN^- = 6 + 7 + 1 = 14$$
 electrons;  $O_2^- = 8 + 8 + 1$   
= 17 electrons;  $NO^+ = 7 + 8 - 1 = 14$  electrons;  
 $CN^+ = 6 + 7 - 1 = 12$  electrons]

- 10. The ratio of  $\sigma$  to  $\pi$  bonds in mesitylene is :
  - (a) 3

(b) 7

(c) 5

(d) 6

Ans. (b)

[Hint: The structure of mesitylene is:

Total number of σ-bonds Total number of  $\pi$ -bonds = 3

- 11. Both BF<sub>3</sub> and NF<sub>3</sub> are covalent compounds. BF<sub>3</sub> is a nonpolar compound but NF3 is polar. The reason is that:
  - (a) boron is a solid and nitrogen is a gas in free state
  - (b) BF<sub>3</sub> is planar but NF<sub>3</sub> is pyramidal in shape
  - (c) boron is a metalloid while nitrogen is a non-metal
  - (d) atomic size of boron is smaller than that of nitrogen

[Hint: BF3 is planar, hence the dipole moment of the molecule is zero. NF3 is pyramidal, thus it possesses dipole moment. Hence, NF<sub>3</sub> is a polar compound.]

- 12. Which of the following sets of species does not follow octet rule?
  - (a) CO,  $PCl_5$ ,  $PCl_3$ ,  $AICl_3$  (b) CO,  $B_2H_6$ ,  $NH_3$ ,  $H_2O$
  - (c) AlCl<sub>3</sub>, BF<sub>3</sub>, PCl<sub>5</sub>, SF<sub>6</sub>
- (d) H<sub>2</sub>O, NH<sub>3</sub>, CO<sub>2</sub>, AlCl<sub>3</sub>

[Hint: BF<sub>3</sub>, AlCl<sub>3</sub> are electron deficient molecules while in PCl<sub>5</sub> and SF<sub>6</sub> molecules P and S possess more than 8 electrons in their valence shells.]

- 13. Which of the following species is diamagnetic in nature? [A.I.E.E.E. 2005]
  - (a) He<sub>2</sub><sup>+</sup>

Ans. (c)

(b) H<sub>2</sub>

(c)  $H_2^+$ 

(d) H<sub>2</sub>

Ans. (b)

Ans. (b)

[Hint:  $He_2^+$ :  $(\sigma 1s)^2 (\sigma 1s)^1$  one unpaired electron – paramagnetic

 $H_2: (\sigma 1s)^2$  no unpaired electron - diamagnetic

 $H_2^+$ :  $(\sigma 1s)^1$  one unpaired electron - paramagnetic

 $H_2^-: (\sigma 1s)^2 (\mathring{\sigma} 1s)^1$  one unpaired electron - paramagnetic]

- 14. The number and type of bonds between two carbon atoms in calcium carbide are: [A.I.E.E.E. 2005]
  - (a) one sigma, one pi
- (b) one sigma, two pi
- (c) two sigma, one pi
- (d) two sigma, two pi

[Hint: Calcium carbide is an ionic compound having anion [:C=C:]<sup>2-</sup>. It has one sigma and two pi bonds.]

15. [In Ag (CN)<sub>2</sub>], the number of  $\pi$ -bonds is :

[A.I.J.M.S. 2006]

(a) 2

(b) 3

(c) 4

(d) 6

Ans. (c)

[Hint: The cyanide ion consists a triple bond, —C=N-, i.e., one sigma and two  $\pi$ -bonds are present: thus, two cyanide groups have  $4\pi$ -bonds.]

- 16. Which of the following molecules/ions does not contain unpaired electrons? [A.I.E.E.E. 2006]
  - (a)  $O_2^{2-}$

(b) B<sub>2</sub>

(c)  $N_2^+$ Ans. (a) (d) O<sub>2</sub>

17. In which of the following molecules/ions are all the bonds [A.I.E.E.E. 2006] not equal?

(a) SF<sub>4</sub>

(b) SiF<sub>4</sub>

(c) XeF<sub>4</sub>

(d) BF<sub>4</sub>

Ans. (a)

[Hint: In  $SF_4$ , sulphur undergoes  $sp^3d$  hybridization. It contains two axial and two equatorial bonds and one position is occupied by a lone pair of electrons.]

- 18. H<sub>2</sub>, Li<sub>2</sub>, B<sub>2</sub> each has bond order equal to 1, the order of their stability is:
  - (a)  $H_2 = Li_2 = B_2$
- (c)  $H_2 > B_2 > Li_2$
- (b)  $H_2 > Li_2 > B_2$ (d)  $B_2 > Li_2 < H_2$

Ans. (c)

[Hint: H2, Li2, B2 are not equally stable. Li atom is much larger in size than H-atom. The bond length in Li2 is much larger than bond length in H2. Moreover, Li2 molecule has two electrons in the antibonding molecular orbital while  $H_2$  has no electrons in the antibonding molecular orbital. Thus, Li<sub>2</sub> is less stable than H<sub>2</sub> (Bond energy of Li<sub>2</sub> = 110 kJ  $\text{mol}^{-1}$  + Bond energy of  $H_2 = 438 \text{ kJ mol}^{-1}$ ). Boron atom is smaller than lithium atom but larger than hydrogen atom. The B2 is more stable than Li2 but less stable than  $H_2$  (Bond energy of  $B_2 = 290$  kJ mol<sup>-1</sup>).]

- 19. Which of the following pair is expected to have the same bond order?
  - (a)  $O_2$ ,  $N_2$
- (b)  $O_2^+$ ,  $N_2^-$
- (c) O<sub>2</sub>, N<sub>2</sub><sup>+</sup>
- (d)  $O_2$ ,  $N_2$

**[Hint:**  $O_2^+$ ,  $N_2^-$  — Each has 15 electrons. Bond order =  $\frac{1}{2}$  (10 – 5)

- 20. Pick out the incorrect statement:
  - (a) In PCl<sub>5</sub>, P atom is sp<sup>3</sup>d hybridized and has trigonal bipyramidal geometry
  - (b) PCl<sub>5</sub> on hydrolysis forms oxychloride
  - (c) PCl5 acts as a Lewis acid
  - (d) In PCl<sub>5</sub>, the axial chlorine atoms are closer to central P atom than equatorial chlorine atoms

Ans. (d)

# **OBJECTIVE QUESTIONS**

## Set I: This set contains questions with single correct answer.

1.	When two atoms combine to form a molecule:			(a) S and Q	□ (b) P and I	₹ /	
	(a) energy is released			(c) S and R	☐ (d) S and I	•	
	(b) energy is absorbed			[Hint: As Q is chlorine	and S is potass	ium, so they i	form
	(c) energy is neither released nor absorbed			KCl which is an		•

# **Objective Questions for IIT ASPIRANTS**

- Which of the following halides has different bond lengths?
  - (a) BCl<sub>3</sub>

(b) CC1<sub>4</sub>

(c) BeC1<sub>2</sub>

(d) PC15

[Hint: PCl5 has two types of bonds axial and equatorial. These two types of bonds have different bond lengths.]

- Which among the following has highest boiling point?

(b) He

(c) Ne

(d) Xe

[Hint: Xenon has highest boiling point because it has maximum van der Waals' forces due to the possession of more

- In which solvent NaCl has maximum solubility?
  - (a)  $H_2O$

(b) C<sub>2</sub>H<sub>5</sub>OH

(c) CH<sub>3</sub>COCH<sub>3</sub>

- (d) C<sub>2</sub>H<sub>5</sub>OC<sub>2</sub>H<sub>5</sub>
- [Hint: NaCl is an ionic compound. Solubility of an ionic compound depends on the value of dielectric constant of the solvent. Higher the value of dielectric constant of the solvent more is the solubility of the ionic compound.

Solvent Dielectric constant 80

H<sub>2</sub>O C<sub>2</sub>H<sub>5</sub>OH CH<sub>3</sub>COCH<sub>3</sub>

C2H5OC2H5

- Which has maximum covalent character?
- (a) NaCl

(b) SiCl<sub>4</sub>

(c) AICl<sub>3</sub>

(d) MgCl<sub>2</sub>

[Hint: Polarisation in the molecule increases with increase of charge and decreases in size of the cation when the anion

- 5. If  $\mu_1$  and  $\mu_2$  are the two dipole moments in the molecule with an angle  $\theta$  between them, then the resultant dipole moment will be:
  - (a)  $\mu = \mu_1^2 + \mu_2^2 + 2\mu_1\mu_2 \cos \theta$
  - (b)  $\mu = \mu_1^2 + \mu_2^2 2\mu_1\mu_2 \cos \theta$
  - (c)  $\mu = (\mu_1^2 + \mu_2^2 + 2\mu_1\mu_2 \cos \theta)^{\frac{1}{2}}$
  - (d)  $\mu = (\mu_1^2 + \mu_2^2 + 2\mu_1\mu_2 \cos \theta)^{\frac{1}{3}}$
- The dipole moment of HBr is  $2.6 \times 10^{-30}$  cm and the interatomic spacing is 1.41 Å. The percentage of ionic character in HBr is:
  - (a) 10.5

(b) 11.5

(c) 12.5

(d) 13.5

Observed dipole moment [Hint:% ionic character = Theoretical dipole moment

Theoretical dipole moment of a 100% ionic character  $= e \times d = (1.6 \times 10^{-19} \text{C}) \times (1.41 \times 10^{-10} \text{ m})$  $= 2.256 \times 10^{-29}$  cm]

- 7. The boiling point of p-nitrophenol is higher than that of onitrophenol because:
  - (a) p-nitrophenol has intermolecular hydrogen bonding while o-nitrophenol has intramolecular hydrogen
  - (b) p-nitrophenol has intramolecular hydrogen bonding while o-nitrophenol has intermolecular hydrogen bonding.
  - (c) -NO2 group at p-position behaves in a different way than that of e-position.

(d) Hydrogen bonding exists in p-nitrophenol but no hydrogen bonding is present in o-nitrophenol.

[Hint: Intramolecular H-bonding is present in o-nitrophenol which lowers its boiling point while intermolecular Hbonding is present in p-nitrophenol which increases its boiling point.]

- 8. NO<sub>2</sub> and N<sub>2</sub>O<sub>4</sub> are two forms of nitrogen dioxide. One exists in gaseous state while other in liquid state. The nature of NO<sub>2</sub> and N<sub>2</sub>O<sub>4</sub> forms are:
  - (a) both are paramagnetic
  - (b) both are diamagnetic
  - (c) NO<sub>2</sub> is paramagnetic while N<sub>2</sub>O<sub>4</sub> is diamagnetic
  - (d) NO<sub>2</sub> is diamagnetic while N<sub>2</sub>O<sub>4</sub> is paramagnetic

[Hint: NO2 is an odd electron molecule N

N<sub>2</sub>O<sub>4</sub>, has no unpaired electron.

$$N-N = 0$$

9. The formal charge of the O-atoms in

$$| : O = N = O : |$$
 is:

(a) -2

(c) 0

[Hint: Formal charge = total valence electrons in free atom - number of non-bonding electrons - 1/2 number of bonding electrons  $= 6 - 4 - 1/2 \times 4 = 0$ 

- 10. Among the following compounds the one that is polar and has the central atom with  $sp^2$  hybridization is :
  - (a) H<sub>2</sub>CO<sub>3</sub>
- (b) SiF<sub>4</sub>

(d) HClO<sub>2</sub>

[Hint:  $H_2CO_3$  is polar as  $H_2CO_3 \rightleftharpoons 2H^+ + CO_3^2$ . Carbon in  $CO_3^2$  ion is in  $sp^2$  hybridized state.]

11. Which of the following hydrocarbons has the lowest dipole moment?

(a) 
$$\stackrel{\text{CH}_3}{\text{H}} \searrow \text{C} = \text{C} \stackrel{\text{H}}{\swarrow} \text{CH}_3$$
 (b)  $\text{CH}_3\text{C} \equiv \text{CCH}_3$ 

(c)  $CH_3CH_2C = CH$ 

(d)  $CH_2 = CH - C = CH$ 

[Hint: Symmetrical with linear structure will have zero dipole moment.]

- 12. CO<sub>2</sub> is isostructural with:
  - (a) HgCl<sub>2</sub>
- (b) SnCl<sub>2</sub>

(c)  $C_2H_2$ 

(d) NO<sub>2</sub>

[Hint: The structure of CO<sub>2</sub> is linear O=C=O, similarly the structures of HgCl<sub>2</sub> and C<sub>2</sub>H<sub>2</sub> are linear, Cl—Hg—Cl; HC=C-H. SnCl<sub>2</sub> and NO<sub>2</sub> have angular structures.]

- Which one of the following arrangements of molecules is correct on the basis of their dipole moments?
  - (a)  $BF_3 > NH_3 > NF_3$
- (b)  $BF_3 > NF_3 > NH_3$
- (c)  $NH_3 > BF_3 > NF_3$
- (d)  $NH_3 > NF_3 > BF_3$

[Hint: Both NF3 and NH3 have identical shape and a lone pair of electrons on nitrogen. The dipole moment of NH3 is higher than NF3 due to different directions of moments of the N—F and N—H bond. BF3 is a symmetrical molecule. It has zero dipole moment.

14. Lattice energy of BeCO<sub>3</sub> (I), MgCO<sub>3</sub> (II) and CaCO<sub>3</sub> (III) is in order:

(a) I < II < III

(b) I > II > III

(c) I < III < II

(d) II < I < III

[Hint: Lattice energy decreases with increase in size of the ions. The size of the cations  $Be^{2+} < Mg^{2+} < Ca^{2+}$ ]

15. Which of the following have undistorted octahedral structures?

1. SF<sub>6</sub>

2. PF<sub>6</sub>

3.  $SiF_6^{2-}$ 

4. XeF<sub>6</sub>

Select the correct answer using the codes given below:

(a) 2, 3 and 4

(b) 1, 3 and 4

(c) 1, 2 and 3

(d) 1, 2 and 4

**[Hint:** XeF<sub>6</sub> has distorted octahedral structure. Xenon in XeF<sub>6</sub> undergoes  $sp^3d^3$  hybridization giving pentagonal bipyramid with one axis is occupied by a lone pair.]

**16.** Sulphur reacts with chlorine in 1:2 ratio and forms *X*. Hydrolysis of *X* gives a sulphur compound *Y*. What is the hybridization state of central atom in the anion of *Y*?

(a)  $sp^3$ 

(b) sp

(c)  $sp^2$  (d)  $sp^2d$ 

[Hint:  $S + 2Cl_2 \longrightarrow SCl_4$ ;  $SCl_4 + 3H_2O \longrightarrow H_2SO_3 + 4HCl_4$ (X) (Y)

In  $SO_3^{2-}$ , sulphur has  $sp^3$  hybridization.]

17. Identify the correct sequence of increasing number of  $\pi$ -bonds in the structures of the following molecules :

(I) H<sub>2</sub>S<sub>2</sub>O<sub>6</sub>

(II) H<sub>2</sub>SO<sub>3</sub> (III) H<sub>2</sub>S<sub>2</sub>O<sub>5</sub>

(a) I, II, III

(b) II, III; I

(c) II, I, III

(d) I, III, II

List II

18. Match the following lists:
List I

Ethane 2 sp carbons (A) 1.  $6 sp^2$  carbons Ethylene  $2 sp^3$  carbons Acetylene  $2 sp^2$  carbons Benzene 1 sp and 1  $sp^2$  carbons The correct answer is: (A) (B) (C) (D) 3 4 2 (a) (b) 4 5 3 2 5 (c) 1 (d) 2

[Hint: Ethane  $H_3C$ — $CH_3$  ( $2sp^3$  carbons);  $sp^3 sp^3$ Ethylene  $H_2C$ = $CH_2$  ( $2sp^2$  carbons)  $sp^2 sp^2$ Acetylene HC=CH (2sp carbons) sp sp sp spBenzene  $sp^2 - C$   $sp^2 - C$   $sp^2$   $c - sp^2$   $c - sp^2$ 

19. The structure of diborane (B<sub>2</sub>H<sub>6</sub>) contains :

(a) four 2C-2e bonds and two 3C-2e bonds

 $(6 sp^2 carbons)$ 

(b) two 2C-2e bonds and four 3C-2e bonds

(c) two 2C-2e bonds and two 3C-2e bonds

(d) four 2C—2e bonds and four 3C—2e bonds

[Hint: The structure of B2H6 is:

Each boron atom is in  $sp^3$  hybrid state. Each boron has three orbitals associated with one electron each and one empty orbital. Two of orbitals to each boron atom overlap with hydrogen atoms (terminal) to form normal sigma bonds. Thus, four bonds are 2C-2e bonds.

Two hydrogen atoms overlap with rest of the four orbitals forming two 3C—2e bonds as two empty orbitals are involved.]

20. Molecular shapes of SF<sub>4</sub>, CF<sub>4</sub> and XeF<sub>4</sub> are :

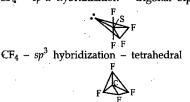

(a) the same with 2, 0 and 1 lone pair of electrons

(b) the same with 1, 1 and 1 lone pair of electrons

(c) different with 0, 1 and 2 lone pair of electrons

(d) different with 1, 0 and 2 lone pair of electrons [Hint: The structures are:

 $SF_4 - sp^3d$  hybridization – trigonal bipyramidal

 $XeF_4 - sp^3d^2$  hybridization – octahedral

21. Which of the following is correct?

(a) The number of electrons present in the valence shell in SF<sub>6</sub> is 12.

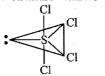

(b) The rates of ionic compounds are very slow.

(c) According to VSEPR, SnCl2 is a linear molecule.

(d) The correct order of ability to form ionic compounds among  $Na^+$ ,  $Mg^{2+}$  and  $Al^{3+}$  is  $Al^{3+} > Mg^{2+} > Na^+$ .

- 22. Which of the following is not isostructural with SiCl<sub>4</sub>?
  - (a)  $PO_4^{3}$
- (b) NH<sub>4</sub><sup>+</sup>
- (c) SCl<sub>4</sub>
- (d) SO<sub>4</sub><sup>2</sup>

[Hint: S in SCl<sub>4</sub> undergoes  $sp^3d$  hybridization. Thus, the molecule has see-saw structure whereas SiCl<sub>4</sub> is tetrahedral.

- 23. The electronegativity difference between N and F is greater than that between N and H, yet the dipole moment of  $NH_3(1.5 D)$  is larger than that of  $NF_3(0.2 D)$ . This is because:
  - (a) in NH<sub>3</sub> as well as in NF<sub>3</sub>, the atomic dipole and bond dipole are in opposite directions
  - (b) in NH<sub>3</sub>, the atomic dipole and bond dipole are in the opposite directions whereas in NF3, these are in the
  - (c) in NH<sub>3</sub> as well as in NF<sub>3</sub>, the atomic dipole and bond dipole are in the same direction
  - (d) in NH<sub>3</sub>, the atomic dipole and bond dipole are in the same direction whereas in NF3, these are in the opposite directions

- 24. In which of the following molecules are all the bonds not equal?
  - (a) AlF<sub>3</sub>

(b) NF<sub>3</sub>

(c) ClF<sub>3</sub>

(d) BF<sub>2</sub>

[Hint: Cl in CIF<sub>3</sub> is in  $sp^3d$  hybridization. The molecule has T-shape structure.]

- Which of the following is not a correct statement?
  - (a) Every AB<sub>5</sub> molecule does in fact have square pyramidal structure.
  - (b) Multiple bonds are always shorter than corresponding single bonds.
  - (c) The electron deficient molecules act as Lewis acids.
  - (d) The canonical structures have no real existence.

[Hint: AB5 molecule can be either square pyramidal as IF5 or trigonal bipyramid as PCl<sub>5</sub>.]

- Specify the coordination geometry around and hybridization of N and B atoms in the 1:1 complex of BF<sub>3</sub> and NH<sub>3</sub>:
  - (a) N: tetrahedral, sp<sup>3</sup>, B: tetrahedral, sp<sup>3</sup>
  - (b) N: pyramidal, sp<sup>3</sup>, B: pyramidal, sp<sup>3</sup>
  - (c) N: pyramidal, sp3, B: planar, sp2
  - (d) N: pyramidal,  $sp^3$ , B: tetrahedral,  $sp^3$

[Hint: The lone pair present on nitrogen in ammonia molecule is donated to boron as BF3 is an electron deficient molecule forming a coordinate bond.

Both N and B are in sp3-hybrid state, i.e., two tetrahedral are joined with each other.]

- 27. Identify the correct order of decreasing bond strength in the bonds formed by 2s-2s, 2p-2p and 2s-2p overlapping:
  - (a) 2s-2s > 2s-2p > 2p-2p
- (b) 2s-2s > 2p-2p > 2s-2p
- (c) 2p-2p > 2s-2p > 2s-2s
- (d) 2p-2p > 2s-2s > 2s-2p

[Hint: Bond strength depends on the extent of overlapping. Maximum overlapping occurs in the case of p-orbitals.]

- The hybridization of I in ICl<sub>2</sub> is:
  - (a) sp

(b)  $sp^2$ 

- (c)  $sp^3$
- (d)  $dsp^2$

[Hint: State of hybridization, H = 1/2[7 + 2 - 1 + 0] = 4or sp<sup>3</sup>-hybridized]

- 1. (d) 2. (d) **11.** (b) **12.** (a,c)
- 3. (a)

- 21. (a)

# Matrix Matching Questions for IIT Aspirants

Match List-I with List-II:

List-I

List-II

- (a) Molecule with sp hybrid
- (p) H-C=C-H

carbon

- (b) Allene (q)  $CH_2 = C = CH_2$
- (c) Electron deficient
- (r) PCl<sub>5</sub>
- (d) Expanded octet
- (s) BeCl<sub>2</sub>
- 2. Match List-I with List-II:

List-I

List-II

- (a) PCl<sub>5</sub>
- (p) Two axial bonds + three lone pairs
- (b) XeF<sub>2</sub>
- (q) Two axial + two equitorial bonds
- (c) SF<sub>4</sub>
- (r) Two axial + one equitorial bonds
- (d) CIF<sub>3</sub>
- (s) Three equitorial + two axial bonds
- Match the molecular species in List-I with their shape in

List-I

List-II

- (a) Linear shape
- (p) CS<sub>2</sub>
- (b) sp hybridization
- (q) XeF<sub>2</sub>
- (c)  $sp^3d$  hybridization
- (r)  $C_2H_2$
- (d) CO2 is isostructural to
- (s) NCO

(c)  $sp^{3}d^{3}$ 

List-I and shape in List-III:

- List-III
- (p)  $d_{xy}$ ,  $d_{yz}$ ,  $d_{zx}$ 
  - (q)  $d_{x^2-y^2}$ ,  $d_{z^2}$

4. Match the orbitals in List-II with the hybridization in

- (u) Octahedral (v) Pentagonal
- - bipyramidal
- (r) d<sub>7</sub>2 (w) Trigonal

bipyramidal

5. Match the molecular species in List-I and their magnetic and molecular orbital properties in List-II:

List-I

List-I

(a)  $sp^3d$ 

(b)  $sv^3d^2$ 

List-II (p) Bond order = 2

(a)  $O_2$ 

(b)  $N_2$ 

(q) Diamagnetic

(c) H<sub>2</sub> (d)  $O_2^{2-}$ 

- (r) Bond order = 3
- (s) Paramagnetic

(a-q, r, p, s)

- (a-p, q) (a-s)
- (b-q) (b-p)

(b-p, r, s)

(c-s)

(c-q)

- (d-r)(d-r)(d-p)
- (c-q)

- (b-q-u)
- (c-p-v)
- (a-r-w) (a-p, s)
- (b-q, r)
- (d-q) (c-q)

# **Assertion-Reason Type Questions**

The questions given below consist of an Assertion (A) and **Reason (R).** Use the following key to choose the correct answer.

- (a) If both (A) and (R) are correct and (R) is the correct explanation of the (A).
- (b) If both (A) and (R) are correct but (R) is not the correct explanation of the (A).
- (c) If (A) is correct but (R) is incorrect.
- (d) If both (A) and (R) are incorrect.
- 1. (A) Bond order in a molecule can assume any value, positive or negative, integral or fractional including zero.
  - (R) It depends upon the number of electrons in the bonding and antibonding orbitals. [A.I.LM.S. 1994]
- 2. (A) Ionic compounds tend to be non-volatile.
  - (R) Intermolecular forces in these compounds are weak. [A.I.LM.S. 1994]
- 3. (A) The atoms in a covalent molecule are said to share electrons, yet some covalent molecules are polar.
  - (R) In polar covalent molecule, the shared electrons spend more time on the average near one of the atoms.
    - [A.I.I.M.S. 1996]

- 4. (A) Nitrogen is inreactive at room temperature but becomes reactive at elevated temperature (on heating or in the presence of catalysts).
  - (R) In nitrogen molecule, there is extensive delocalization of electrons. [A.I.I.M.S. 1996]
- 5. (A) Water is a good solvent for ionic compounds but poor one for covalent compounds.
  - (R) Hydration energy of ions releases sufficient energy to overcome lattice energy and break hydrogen bonds in water while covalent bonded compounds interact so weakly that even van der Waals' forces between molecules of covalent compounds cannot be broken.

[A.I.I.M.S. 1996]

- 6. (A) Na<sub>2</sub>SO<sub>4</sub> is soluble in water while BaSO<sub>4</sub> is insoluble.
  - (R) Lattice energy of BaSO<sub>4</sub> exceeds its hydration energy. [A.I.I.M.S. 1997]
- 7. (A) NO<sub>3</sub> is planar while NH<sub>3</sub> is pyramidal.
  - (R) N in  $NO_3$  is  $sp^2$  and in  $NH_3$  it is  $sp^3$  hybridized.

[A.I.I.M.S. 1997]

- 8. (A) N<sub>2</sub> and NO<sup>+</sup> both are diamagnetic substances.
  - (R) NO<sup>+</sup> is isoelectronic with N<sub>2</sub>.

[A.I.I.M.S. 1997]

- 9. (A) The bond angle of PBr<sub>3</sub> is greater than PH<sub>3</sub> but the bond angle of NBr<sub>3</sub> is less than NH<sub>3</sub>.
   (R) Electronegativity of phosphorus atom is less than that
  - (R) Electronegativity of phosphorus atom is less than that of nitrogen. [A.I.I.M.S. 1997]
- 10. (A) The electronic structure of  $O_3$  is

(R) Structure is not allowed because octet around

'O' cannot be expanded.

[I.I.T. 1998]

- 11. (A) LiCl is predominantly a covalent compound.
  - (R) Electronegativity difference between 'Li' and 'Cl' is too small. [I.I.T. 1998]
- 12. (A) Bond order can assume any value including zero.
  - (R) Higher the bond order, shorter is the bond length and greater is the bond energy. [A.I.I.M.S. 1999]

- 13. (A) The dipole moment helps to predict whether molecule is polar or non-polar.
  - (R) The dipole moment helps to predict the geometry of molecules. [A.I.I.M.S. 1999]
- 14. (A) The O—O bond length in H<sub>2</sub>O<sub>2</sub> is shorter than that of O<sub>2</sub>F<sub>2</sub>.
  - (R)  $H_2O_2$  is an ionic compound.

[A.I.I.M.S. 2003]

- 15. (A) All F—S—F angles in SF<sub>4</sub> are greater than 90° but less than 180°.
  - (R) The lone pair-bond repulsion is weaker than bond pair-bond repulsion. [A.I.I.M.S. 2004]
- 16. (A) B<sub>2</sub> molecule is diamagnetic.
  - (R) The highest occupied molecular orbital is of  $\sigma$  type. [Hint: In B<sub>2</sub>, total number of electrons are  $10 \ (\sigma 1s)^2 (\mathring{\sigma} 1s)^2 \ (\sigma 2s)^2 (\mathring{\sigma} 2s)^2 (\pi 2p_y)^1 (\pi 2p_z)^1$ -paramagnetic. The highest occupied orbital is of  $\pi$  type.]
- 17. (A) The S—S—S bond angle in S<sub>8</sub> molecule is 105°.
  - (R) S<sub>8</sub> has V-shape.

[A.I.I.M.S. 2008]

- 18. (A) Fluorine molecule has bond order one.
  - (R) The number of electrons in antibonding molecular orbitals is two less than in bonding molecular orbitals.

    [A.I.I.M.S. 2008]

# **THOUGHT TYPE QUESTIONS**

# THOUGHT 1

When anions and cations approach each other, the valence shell of anions are pulled towards cation nucleus and thus, shape of anion is deformed. The phenomenon of deformation of anion by a cation is known as polarization and the ability of the cation to polarize the anion is called as polarizing power of cation. Due to polarization, sharing of electrons occurs between two ions to some extent and the bond shows some covalent character.

The magnitude of polarization depends upon a number of factors. These factors were suggested by Fajan and are known as Fajan's rules.

- (i) Greater is the polarization in a molecule, more is covalent character.
- (ii) As the charge on cation increases, its tendency to polarize the anion increases.
- (iii) As the size of the cation decreases or size of the anion increases, the polarization increases.
- (iv) The cations with 18 electrons in the outermost shell bring greater polarization of the anion than those with inert gas configuration even both the cations have same size and same charge.

- Considering BeCl<sub>2</sub>, MgCl<sub>2</sub>, CaCl<sub>2</sub> and BaCl<sub>2</sub>, predict which
  of the following statements is true?
  - (a) BeCl<sub>2</sub> is least ionic out of the given chlorides
  - (b) Covalent character increases as the atomic number of the metal atom increases
  - (c) BeCl<sub>2</sub> has the highest melting point among the given chlorides
  - (d) All are highly ionic compounds
- 2. In which of the halides, there is maximum polarization?
  - (a) AlF<sub>3</sub>
- (b) AlCl<sub>3</sub>
- (c) AlBr<sub>3</sub>
- (d) AlI<sub>3</sub>
- 3. Which is most covalent in nature?
  - (a) NaCl
- ( MgCl<sub>2</sub>

- (c) AICL
- (d) CaCl<sub>2</sub>
- 4. Non-aqueous solvent like ether is added to the mixture of LiCl, NaCl and KCl. Which will be extracted into ether?
  - (a) NaCl
- (b) LiCl

(c) KC1

- (d) None
- 5. Which has the minimum melting point?
  - (a) CaF<sub>2</sub>
- (b) CaCl<sub>2</sub>
- (c) CaBr<sub>2</sub>
- (d) CaI<sub>2</sub>

#### THOUGHT 2

Covalent molecules formed by heteroatoms bound to have some ionic character. The ionic character is due to shifting of the electron pair towards A or B in the molecule AB. Hence, atoms acquire small and equal charge but opposite in sign. Such a bond which has some ionic character is described as polar covalent bond. Polar covalent molecules can exhibit dipole moment. Dipole moment is equal to the product of charge separation, q and the bond length, d for the bond. The unit of dipole moment is Debye. One Debye is equal to  $10^{-18}$  esu cm.

Dipole moment is a vector quantity. It has both magnitude and direction. Hence, dipole moment of molecules depends upon the relative orientation of the bond dipoles, but not on the polarity of bonds alone. A symmetrical structure shows zero dipole moment. Thus, dipole moments help to predict the geometry of the molecules. Dipole moment values can be used to distinguish between *cis*- and *trans*-isomers; *ortho-*, *meta-* and *para-*forms of a substance, etc. The percentage of ionic character of a bond can be calculated by the application of the following formula:

#### % ionic character

1. Which of the following compounds have zero dipole moments?

[Hint: Symmetrical forms have zero dipole moments.]

2. Which are non-polar molecules?

(a) XeF<sub>4</sub>

(b) BF<sub>3</sub>

(c) NH<sub>3</sub>

(d) H<sub>2</sub>O

3. A diatomic molecule has a dipole moment of 1.2 D. If the bond length is  $1.0 \times 10^{-8}$  cm, what fraction of charge does exist on each atom?

(a) 0.1

(b) 0.2

(c) 0.25

(d) 0.3

[Hint : Charge =  $\frac{\text{Dipole moment}}{\text{Bond length}} = \frac{1.2 \times 10^{-18}}{1.0 \times 10^{-8}} = 1.2 \times 10^{-10} \text{esu}$ 

Fraction of electronic charge =  $\frac{1.2 \times 10^{-10}}{4.8 \times 10^{-10}}$  = 0.25]

**4.** Arrange the following compounds in increasing order of dipole moments, toluene (I), *o*-dichlorobenzene (II),

m-dichlorobenzene (III) and p-dichlorobenzene (IV):

(a) IV < I < II < III

(b) I < IV < II < III

(c) IV < I < III < II

(d) IV < II < I < III

- 5. The dipole moment of NF<sub>3</sub> is very much less that of NH<sub>3</sub> because :
  - (a) number of lone pairs in NF<sub>3</sub> is much greater than in NH<sub>3</sub>
  - (b) unshared electron pair is not present in NF3 as in NH3
  - (c) both have different shapes
  - (d) of different directions of moments of N—H and N—F bonds
- 6. A covalent molecule, x-y, is found to have a dipole moment of  $1.5 \times 10^{-29}$  cm and a bond length 150 pm. The percentage of ionic character of the bond will be:

(a) 50%

(b) 62.5%

and the second second second second second second second second second second second second second second second

(c) 75% (d) 90%

[**Hint**:  $\mu_{cal} = 1.602 \times 10^{-19} \text{C} \times 150 \times 10^{-12} \text{ m} = 2.4 \times 10^{-29} \text{ cm}$   $\mu_{obs} = 1.5 \times 10^{-29}$ % ionic character  $= \frac{1.5 \times 10^{-29}}{2.4 \times 10^{-29}} \times 100 = 62.5$  ]

#### THOUGHT 3

According to the concept of resonance, whenever a single Lewis structure cannot describe a molecule accurately, a number of structures with almost same energy and similar positions of nuclei, bonding and non-bonding pairs of electrons are taken as canonical structures of the resonance hybrid which describes the molecule accurately. In general, the resonance stabilizes the molecule as the energy of resonance hybrid is less than the energy of any single canonical structure and resonance averages the bond characteristics as a whole. Actually resonance hybrid does not oscillate between the canonical forms but it is a definite form and has a definite structure which cannot be written on paper. The contributing structures should be such that negative charge resides on more electronegative and positive charge on the electropositive. Like charges should not reside on atoms close together in the canonical forms.

As a result of resonance, the bond order changes in many molecules or ions.

Total number of bonds between two atoms in all the structures

Total number of resonating structures

Formal charges on atoms in the molecule helps in selecting most favourable canonical form to the hybrid form.

 Consider the following statements about the resonating structures of benzene.

$$\underbrace{\bigcirc \longleftrightarrow \bigcirc \longleftrightarrow \bigcirc \longleftrightarrow \bigcirc \longleftrightarrow \bigcirc \longleftrightarrow \bigcirc
}_{\text{Kekule's}}$$

$$\underbrace{\bigcirc \longleftrightarrow \bigcirc \longleftrightarrow \bigcirc \longleftrightarrow \bigcirc
}_{\text{Dewar's}}$$

The correct statement(s) is/are:

(a) Two Kekule's structures contribute 80% while remaining three Dewar's structures 20% only.

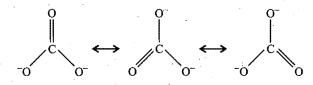

- (b) Because of the resonance, all C—C bonds in benzene become identical.
- (c) Resonance decreases the bond length of C—C single bond and increases the bond length of C=C bond.
- (d) Benzene becomes less stable and more reactive due to resonance.
- 2. The bond order of C—O bond for  $CO_3^{2-}$  ion is:
  - (a) 1.25

(b) 1.33

(c) 1.5

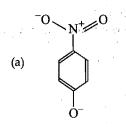

(d) 1.0

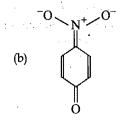

[Hint: The resonance structures of carbonate ion are:

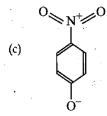

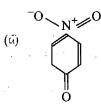

B.O. = 
$$\frac{2+1+1}{3}$$
 = 1.33]

- 3. Which is not true for resonance?
  - (a) Identical bonding
  - (b) Identical arrangement of atoms
  - (c) Same number of paired electrons
  - (d) Structure with nearly same energies
- **4.** The most unlikely representation of resonance structure of *p*-nitrophenoxide ion is:

- 5. Which resonance structure of  $N_2O$  is more favourable than others?
  - (a)  $\vec{N} = \vec{N} = \vec{O}$
- (b)  $: N = \stackrel{+}{N} O$ :
- (c)  $^{2-}$ : $\overset{+}{N} = \overset{+}{O}$ :
- (d) None

[Hint: Negative charge should be present on more electronegative atom.]

#### **THOUGHT 4**

Molecular orbital theory is based on the principle of linear combination of atomic orbitals. According to this approach when atomic orbitals of the atoms come closer, they undergo constructive interference as well as destructive interference giving molecular orbitals, *i.e.*, two atomic orbitals overlap to form two molecular orbitals, one of which lies at a lower energy level (bonding molecular orbital) than the other at higher energy level (antibonding molecular orbital). Each molecular orbital can hold one or two electrons in accordance with Pauli's exclusion principle and Hund's rule of maximum multiplicity. For molecules upto  $N_2$ , the order of filling of orbitals is:

$$\sigma(1s)$$
,  $\mathring{\sigma}(1s)$ ,  $\sigma(2s)$ ,  $\mathring{\sigma}(2s)$ ,  $\pi(2p_x) = \pi(2p_y)$ ,  $\sigma(2p_z)$ ,  $\mathring{\pi}(2p_x) = \mathring{\pi}(2p_y)$ ,  $\mathring{\sigma}(2p_z)$ 

and for molecules after  $N_2$ , the order of filling is:

$$\sigma(1s), \ \mathring{\sigma}(1s), \ \sigma(2s), \ \sigma(2s), \ \sigma(2p_z), \ \pi(2p_x) = \pi(2p_y), \ \mathring{\pi}(2p_x) = \mathring{\pi}(2p_y), \ \mathring{\sigma}(2p_z)$$

Bond order =  $\frac{1}{2}$  [bonding electrons – antibonding electrons]

Bond order gives the following information:

- (i) If bond order is greater than zero, the molecule/ion exists otherwise not.
- (ii) Higher the bond order, higher is the bond dissociation energy.
- (iii) Higher the bond order, greater is the bond stability.
- (iv) Higher the bond order, shorter is the bond length.
- **1.** The relative stabilities of CN, CN<sup>+</sup> and CN<sup>-</sup> are in the order of :
  - (a)  $CN > CN^{+} > CN^{-}$
- (b) CN7 > CN > CN+
- (c)  $CN^- > CN^+ > CN$
- (d)  $CN^+ > CN > CN^-$

[**Hint**: Bond order:  $CN = \frac{9-4}{2} = 2.5$ ,  $CN^- = \frac{10-4}{2} = 3$ ,  $CN^+ = \frac{8-4}{2} = 2$ ]

- 2. Molecular orbital theory is preferred over valence bond theory as it can explain:
  - (a) bond strength
  - (b) geometry of molecule
  - (c) the magnetic nature of the molecule
  - (d) none of the above
- 3.  $O_2^2$  will have:
  - (a) bond order lower than O2
  - (b) bond order higher than O2
  - (c) bond order equal to O2
  - (d) bond order equal to H2
- 4. Which of the following molecule is paramagnetic?
  - (a) F<sub>2</sub>

(b) O<sub>2</sub>

(c)  $N_2$ 

- (d) H<sub>2</sub>
- 5. In which set of molecules all the species are paramagnetic?
  - (a)  $B_2$ ,  $O_2$ ,  $N_2$
- (b) B<sub>2</sub>, O<sub>2</sub>, NO
- (c)  $B_2$ ,  $F_2$ ,  $O_2$
- (d) B<sub>2</sub>, O<sub>2</sub>, Li<sub>2</sub>
- 6. Which one of the following statements is correct?
  - (a) Bonding molecular orbital is lowered by the same, amount of energy by which antibonding molecular orbital is raised.
  - (b) Bonding molecular orbital is lowered by greater amount of energy than the amount by which antibonding molecular orbital is raised.

- (c) Bonding molecular orbital is lowered by lesser amount of energy than the amount by which antibonding molecular orbital is raised.
- (d) Any one of the above is possible.

- 3.8 Some General Trends in Acidic and Basic Properties

# 3.1 INTRODUCTION

Acids and bases were first recognised as specific classes of compounds because of the distinctive properties exhibited by their aqueous solutions. The properties of acids and bases are listed below:

Properties of acids	Properties of bases
1. Sour* in taste.	Bitterness in taste.
2. Change colours of indicators,	Change colours of indicators, e.g.,
e.g., litmus turns from blue to	litmus turns from red to blue;
red; phenolphthalein turns	phenolphthalein turns from
from pink to colourless.	colourless to pink.
3. Electrolytic conductivity in aqueous solution.	l
4. React with active metals to give hydrogen.	Soapy touch and slippery in nature.
	Basic properties disappear when react with acids (Neutralisation).
6. Decompose carbonates.	

In 1783, **Lavoisier** suggested that acids are the oxy-compounds of non-metals. This view was soon rejected by Davy as a result of his studies on *muriatic acid* (hydrochloric acid). The search for a common factor in acids came to light when the German chemist, **Liebig**, proposed the following definition of an acid in 1830.

# CHAPTER 3

# Acids and Bases

An acid is a compound which contains one or more hydrogen atoms replaceable partially or completely by a metal or a positive radical to produce a salt.

Several theories (concepts) have been proposed to explain the behaviour of acids and bases on the basis of structure and composition, but no single theory explains the overall behaviour of acids and bases. Each of the theory or concept can be applied with advantage in appropriate circumstances. In a given situation, the chemist uses that concept which best suits his purpose.

The most popular theories or concepts are described in this chapter.

### 3.2 ARRHENIUS CONCEPT

This concept was presented in 1887. According to this concept all substances which give H<sup>+</sup> ions when dissolved in water are called acids while those which ionise in water to furnish OH<sup>-</sup> ions are called bases.

$$HA \stackrel{\text{Water}}{=\!=\!=\!=} H^+ + A^-$$
Acids 
$$BOH \stackrel{\text{Water}}{=\!=\!=\!=} B^+ + OH^-$$
Base

Warning: The chemicals in the laboratory should never be tasted as these can be poisonous and prove fatal sometimes.

<sup>\*</sup> The word acid is a Latin word—acidus meaning sour.

The reaction between an acid and a base is termed neutralisation, *i.e.*, neutralisation involves the reaction between H<sup>+</sup> and OH<sup>-</sup> ions to form water.

$$NaOH + HCI \longrightarrow NaCI + H_2O$$
 (Neutralisation)  
Base Acid Salt Water  $OH^- + H^+ \longrightarrow H_2O$ 

Actually free  $H^+$  ions do not exist in water. They combine with solvent molecules, *i.e.*, hydrated to form **hydronium** or **hydroxinium** ( $H_3O^+$ ) ions.

$$H^+ + H_2O \Longrightarrow H_3O^+(aq)$$

Thus, the ionisation of acids in aqueous solutions should be represented as:

$$HCl + H_2O \Longrightarrow H_3O^+(aq) + C\Gamma(aq)$$
  
 $H_2SO_4 + 2H_2O \Longrightarrow 2H_3O^+(aq) + SO_4^{2-}(aq)$ 

Evidence for Arrhenius theory comes from the heat of reaction,  $\Delta H^{\circ}$ , for the neutralisation of a strong acid by a strong base. This neutralisation is essentially the reaction of  $H_3O^+(aq)$  with  $OH^-(aq)$  and should, therefore, always give the same  $\Delta H^{\circ}$  per mole of water formed. Experimentally, it is found that all neutralisation between strong acids and strong bases have the same  $\Delta H^{\circ}$  (–55.90 kJ per mole of  $H^+$ ).

#### Limitations of Arrhenius Concept

- (i) It is applicable only to aqueous solutions. For the acidic or basic properties, the presence of water is absolutely necessary. Dry HCl shall not act as an acid.
- (ii) The concept does not explain acidic or basic properties of acids and bases in non-aqueous solvents respectively.
- (iii) It fails to explain the acidic nature of the non-protic compounds such as  $SO_2$ ,  $NO_2$ ,  $CO_2$ ,  $P_2O_5$ , etc., which do not have hydrogen for furnishing  $H^+$  ions.
- (iv) It fails to explain the basic nature of compounds like NH<sub>3</sub>, Na<sub>2</sub>CO<sub>3</sub>, etc., which do not have OH in the molecule to furnish OH<sup>-</sup> ions.
- (v) It fails to explain the acidic nature of certain salts such as  $AlCl_3$  in aqueous solution.

#### Modified Arrhenius Concept

The modified concept rectifies most of the limitations. Water is a weak electrolyte and ionises to a very small extent.

$$\frac{H_2O \Longrightarrow H^+ + OH^-}{H^+ + H_2O \Longrightarrow H_3O^+}$$

$$\frac{H^+ + H_2O \Longrightarrow H_3O^+ + OH^-}{H_2O + H_2O \Longrightarrow H_3O^+ + OH^-}$$

Water is also neutral in nature, *i.e.*,  $H_3O^+$  and  $OH^-$  ion concentrations are equal.

$$[H_3O^+] = [OH^-]$$

The substances which increase the concentration of  $H_3O^+$  ions in water act as acids while those which increase the concentration of  $OH^-$  ions act as bases.  $SO_2$  increases  $H_3O^+$  ion concentration. Hence, it is an acid.

$$SO_2 + H_2O \longrightarrow H_2SO_3 \stackrel{Water}{\Longleftrightarrow} H_3O^+ + HSO_3^-$$

Similarly, NH<sub>3</sub> behaves as a base as it increases OH<sup>-</sup> ion concentration.

$$NH_3 + H_2O \longrightarrow NH_4OH \Longrightarrow NH_4^+ + OH^-$$

#### Basicity or Protocity of an Acid

The basicity of an acid is the number of hydrogen ions which can be furnished by one molecule of the acid upon dissociation. An acid liberating 1, 2 or 3 H<sup>+</sup> ions are respectively known as monobasic, dibasic and tribasic (monoprotic, diprotic and triprotic). Polyprotic acids usually dissociate in steps.

Acid	Dissociation	Basicity
HCI	HCl <del>←</del> H <sup>+</sup> + Cl <sup>-</sup>	1 [Monoprotic]
HNO <sub>3</sub>	$HNO_3 \rightleftharpoons H^+ + NO_3^-$	1 [Monoprotic]
CH <sub>3</sub> COOH	CH <sub>3</sub> COOH ⇌ H <sup>+</sup> + CH <sub>3</sub> COO <sup>-</sup>	1 [Monoprotic]
H <sub>2</sub> SO <sub>4</sub>	$H_2SO_4 \rightleftharpoons H^+ + HSO_4^-$ $HSO_4^- \rightleftharpoons H^+ + SO_4^{2}$	
	$H_2SO_4 \rightleftharpoons 2H^+ + SO_4^{2-}$	2 [Diprotic]
H <sub>3</sub> PO <sub>4</sub>	$H_3PO_4 \rightleftharpoons H^+ + H_2PO_4^-$	
*	$H_2PO_4^- \rightleftharpoons H^+ + HPO_4^{2^-}$ $HPO_4^{2^-} \rightleftharpoons H^+ + PO_4^{3^-}$	
	$H_3PO_4 \Longrightarrow 3H^+ + PO_4^{3-}$	3 [Triprotic]
$H_3PO_3$	$H_3PO_3 \Longrightarrow H^+ + H_2PO_3^-$	
r J	$H_2PO_3^- \iff H^+ + HPO_3^{2-}$	of the second
	$H_3PO_3 \iff 2H^+ + HPO_3^{2-}$	2 [Diprotic]
H <sub>3</sub> PO <sub>2</sub>	$H_3PO_2 \iff H^+ + H_2PO_2^-$	1 [Monoprotic]

It is clear from the above table that basicity of an acid is not necessarily the number of hydrogen atoms present in one molecule of the acid but the number of hydrogen ions furnished by one molecule. An acid is generally termed as **polybasic** or **polyprotic** when a molecule of it produces more than one  $H^+$  ion in aqueous solution.

#### Acidity or Hydroxicity of a Base

The acidity or hydroxicity of a base is the number of hydroxyl ions produced from one molecule of the base on dissociation. A base liberating 1, 2 or 3 OH<sup>-</sup> ions are respectively known as monoacidic or monohydroxic, diacidic or dihydroxic, triacidic or trihydroxic. Sodium hydroxide (NaOH), ammonium hydroxide (NH<sub>4</sub>OH), potassium hydroxide (KOH) are monoacidic or monohydroxic bases while calcium hydroxide [Ca(OH)<sub>2</sub>], barium hydroxide [Ba(OH)<sub>2</sub>] are diacidic or dihydroxic bases.

[Acidity may also be considered as the number of H<sup>+</sup> ions that can be accepted by one molecule of the base.]

#### Strength of Acids and Bases

The strength of an acid or a base in Arrhenius concept is based on the extent of ionisation or the equilibrium constant. The equilibrium constant,  $K_a$  for the acid, HX, is:

$$K_a = \frac{[H^+][X^-]}{[HX]}$$

The equilibrium constant,  $K_b$  for the acid, BOH, is:

$$K_b = \frac{[B^+][\mathrm{OH}^-]}{[B\mathrm{OH}]}$$

The acids which are highly ionised in aqueous solutions, *i.e.*, giving large number of hydrogen ions are known as strong acids. The value of  $K_a$  for strong acids is higher than 0.1. HClO<sub>4</sub>, HNO<sub>3</sub>, H<sub>2</sub>SO<sub>4</sub>, HCl, etc., are very strong acids. The value of  $K_a$  is very small for weak acids such as CH<sub>3</sub>COOH, H<sub>3</sub>PO<sub>3</sub>, H<sub>2</sub>CO<sub>3</sub>, H<sub>3</sub>BO<sub>3</sub>, etc. For example,  $K_a$  value of CH<sub>3</sub>COOH is 1.8 × 10<sup>-5</sup> at 25°C. In other words, in the case of weak acid, the ionisation is only slight and the major part remains as undissociated molecules.

The bases which are highly dissociated in aqueous solution to produce large number of  $OH^-$  ions are called strong alkalies. The value of  $K_b$  for strong alkalies is higher than 0.1. NaOH, KOH, Ba(OH)<sub>2</sub>, etc., are strong bases. The value of  $K_b$  is low for weak bases such as  $NH_4OH$ ,  $Al(OH)_3$ ,  $Fe(OH)_3$ , etc.

### 3.3 BRONSTED-LOWRY CONCEPT

The concept was proposed independently by Bronsted and Lowry in 1923. According to this concept acids are the species capable of donating the proton in a reaction while bases are the species capable of accepting the proton in a reaction, *i.e.*, acids are proton donors (protogenic) and bases are proton acceptors (protophilic). Consider the reaction,

$$HC1 + H_2O \Longrightarrow H_3O^+ + C1^-$$

In this reaction, HCl acts as an acid because it donates a proton to the water molecule. Water, on the other hand, behaves as a base by accepting a proton from an acid. Some other examples are:

$$CH_3COOH + H_2O \Longrightarrow H_3O^+ + CH_3COO^-$$
  
 $CO_2 + 2H_2O \Longrightarrow H_3O^+ + HCO_3^-$   
 $NH_4^+ + H_2O \Longrightarrow H_3O^+ + NH_3$   
 $HSO_4^- + H_2O \Longrightarrow H_3O^+ + SO_4^{2-}$ 

Consider the reaction,

$$NH_3 + H_2O \Longrightarrow NH_4^+ + OH^-$$

In this reaction, water acts as an acid as it donates a proton to  $NH_3$  molecule and  $NH_3$  behaves as a base as it accepts a proton. Some other examples are :

$$OH^- + H^+ \Longrightarrow H_2O$$
  
 $CN^- + H_2O \Longrightarrow HCN + OH^-$   
 $NO_2^- + H_2O \Longrightarrow HNO_2^- + OH^-$ 

It is evident from above examples that  $H_2O$  can act both as an acid and a base.  $H_2O$  is thus regarded as amphiprotic.

 $NH_3$  and  $CH_3COOH$  also act as  $\boldsymbol{amphiprotic.}$ 

When an acid loses a proton, the residual part of it has a tendency to regain a proton. Therefore, it behaves as a base.

Acid 
$$\rightleftharpoons$$
 H<sup>+</sup> + Base

The acid and base which differ by a proton are known to form a **conjugate pair**. Consider the following reaction:

$$CH_3COOH + H_2O \Longrightarrow H_3O^+ + CH_3COO^-$$

It involves two conjugate pairs. The acid-base pairs are :

$$\begin{array}{cccc} CH_{3}COOH & \stackrel{-H^{+}}{\Longrightarrow} & CH_{3}COO^{-} & ; & H_{2}O & \stackrel{+H^{+}}{\Longrightarrow} & H_{3}O^{+} \\ & Acid & \stackrel{+H^{+}}{\Longrightarrow} & Base & Base & -H^{+} & Acid \end{array}$$

If in the above reaction, the acid,  $CH_3COOH$  is labelled acid<sub>I</sub> and its conjugate base,  $CH_3COO^-$  as base<sub>I</sub> and the  $H_2O$  is labelled as base<sub>II</sub> and its conjugate acid,  $H_3O^+$  as acid<sub>II</sub>, the reaction can be written as :

$$Acid_I + Base_{II} \Longrightarrow Base_I + Acid_{II}$$

Thus, any acid-base reaction involves two conjugate pairs, *i.e.*, when acid reacts with a base, another acid and base is formed. Some more examples are given below:

$$\begin{array}{c} \text{Acid}_{\text{I}} + \text{Base}_{\text{II}} & \Longrightarrow \text{Acid}_{\text{II}} + \text{Base}_{\text{I}} \\ \text{H}_2\text{O} + \text{NH}_3 & \Longrightarrow \text{NH}_4^+ + \text{OH}^- \\ \text{HCN} + \text{H}_2\text{O} & \Longrightarrow \text{H}_3\text{O}^+ + \text{CN}^- \\ \text{NH}_3 + \text{NH}_3 & \Longrightarrow \text{NH}_4^+ + \text{NH}_2^- \\ \text{H}_2\text{O} + \text{H}_2\text{O} & \Longrightarrow \text{H}_3\text{O}^+ + \text{OH}^- \\ \text{HCl} + \text{NH}_3 & \Longrightarrow \text{NH}_4^+ + \text{Cl}^- \\ \text{HF} + \text{CH}_3\text{COOH} & \Longrightarrow \text{CH}_3\text{COOH}_2^+ + \text{F}^- \\ \text{HCO}_3^- + \text{H}_2\text{O} & \Longrightarrow \text{H}_3\text{O}^+ + \text{CO}_3^2 \\ \text{HNO}_3 + \text{N}_2\text{H}_4 & \Longrightarrow \text{N}_2\text{H}_5^+ + \text{NO}_3 \\ \text{HF} + \text{HNO}_3 & \Longrightarrow \text{H}_2\text{NO}_3^+ + \text{F}^- \\ \text{[Fe(H}_2\text{O)}_6]^{3^+} + \text{H}_2\text{O} & \Longrightarrow \text{H}_3\text{O}^+ + \text{[Fe(H}_2\text{O)}_5\text{(OH)}]^{2^+} \end{array}$$

Thus, every acid has its conjugate base and every base has its conjugate acid. Some commonly occurring conjugate acid-base pairs are listed below:

Acid	Conjugate base	Acid	Conjugate base
$HNO_3$	$NO_3^-$	$H_2SO_4$	$HSO_4^-$
HCl	Cl-	$HSO_4^-$	$SO_4^{2-}$
HBr	Br <sup></sup>	$H_2CO_3$	HCO <sub>3</sub>
H <sub>2</sub> O	OH-	HCO <sub>3</sub>	$CO_3^{2-}$
NH <sub>4</sub>	NH <sub>3</sub>	H <sub>2</sub> S	HS-
CH <sub>3</sub> COOH	CH <sub>3</sub> COO <sup>-</sup>	HS <sup>-</sup>	S <sup>2-</sup>
HCN	CN <sup>-</sup>	$H_3PO_4$	$H_2PO_4^-$
NH <sub>3</sub>	$NH_2^-$	$H_2PO_4^-$	$HPO_4^{2-}$
$H_3PO_2$	$H_2PO_2^-$	$HPO_4^{2-}$	$PO_4^{3-}$

It is clear from the given table that Bronsted-Lowry acids and bases can be molecular, cationic or anionic as listed in the following table:

Type	Acid	Base
Molecular	HClO <sub>4</sub> , HNO <sub>3</sub> , H <sub>3</sub> PO <sub>4</sub> , H <sub>2</sub> SO <sub>4</sub> ,	NH <sub>3</sub> , N <sub>2</sub> H <sub>4</sub> , PH <sub>3</sub> ,
	CH₃COOH, HCl, H₂O	amines, alcohols.
Cationic	NH <sub>4</sub> <sup>+</sup> , N <sub>2</sub> H <sub>5</sub> <sup>+</sup> , PH <sub>4</sub> <sup>+</sup> ,	$[Fe(H_2O)_5OH]^{2+}$ ,
	[Fe(H <sub>2</sub> O) <sub>6</sub> ] <sup>3+</sup> , Na <sup>+</sup> , Ba <sup>2+</sup>	$[Al(H_2O)_5OH]^{2+}$
Anionic	HCO3, HSO4, HSO3,	CI, Br, CN, NH <sub>2</sub> ,
	HS <sup>-</sup> , H <sub>2</sub> PO <sub>4</sub>	$CO_3^{2-}$ , $SO_4^{2-}$ , $OH^{-}$

There is an advantage of Bronsted-Lowry concept that besides water any other solvent, which has the tendency to accept or lose a proton may decide the acidic or basic behaviour of the dissolved substance in that solvent. Moreover, it can be said that the term acid or base is comparative. A substance may act as an acid in one solvent while it behaves as a base in other solvent. Acetic acid acts as an acid in water but behaves as a base in HF.

On the basis of proton interaction, solvents can be classified into four types :

- (i) Protophilic solvents: Solvents which have the tendency to accept protons, *e.g.*, water, alcohol, liquid ammonia, etc.
- (ii) Protogenic solvents: Solvents which have the tendency to donate protons, e.g., water, liquid hydrogen chloride, glacial acetic acid, liquid hydrofluoric acid, etc.
- (iii) Amphiprotic: Solvents which have both the tendencies to accept or donate protons, e.g., water, liquid ammonia, alcohol, etc.
- (iv) Aprotic: Solvents which neither donate nor accept protons, *e.g.*, benzene, carbon tetrachloride, carbon disulphide, etc.

#### Strength of Acids and Bases

The strength of an acid depends upon its tendency to lose its proton and the strength of the base depends upon its tendency to gain the proton.  $K_a$ , the equilibrium constant, of the following reaction gives a quantitative measure of the strength of the acid.

$$HA + H_2O \Longrightarrow H_3O^+ + A^ K_a = \frac{[H_3O^+][A^-]}{[HA]}$$

Larger the value of  $K_a$  indicates that the acid is stronger in nature.

Similarly,  $K_b$  of the following reaction gives the quantitative measure of the strength of the base.

$$B + H_2O \Longrightarrow BH^+ + OH^-$$

$$K_b = \frac{[BH^+][OH^-]}{[B]}$$

Larger the value of  $K_b$  indicates that the base is stronger in nature.

It is further observed that strong acids have weak conjugate bases while weak acids have strong conjugate bases.

Acid-Base Chart Containing Some Common Conjugate Acid-Base Pairs

•	Acid	Conjugate base		Ka	pK <sub>a</sub>
1	н	Γ .		10 <sup>11</sup>	-11
	HClO <sub>4</sub>	ClO <sub>4</sub>		.10 <sup>10</sup>	-10
	HBr	Br <sup>-</sup>	· C-	10 <sup>9</sup>	-9
	HCI	Cl <sup>-</sup> -		10 <sup>7</sup>	<b>-7</b>
- /	H <sub>2</sub> SO <sub>4</sub>	HSO <sub>4</sub>		10 <sup>2</sup>	-2
	H <sub>3</sub> O <sup>+</sup>	H <sub>2</sub> O	-5	1	0.0
Increasing order of acid strength	$H_2SO_3$	HSO <sub>3</sub>	î. Increasing order of basic strength	$1.5 \times 10^{-2}$	1.81
stre	HSO <sub>4</sub>	SO <sub>4</sub> <sup>2-</sup>	cstr	$1.2 \times 10^{-2}$	1.92
acid	$H_3PO_4$	H <sub>2</sub> PO <sub>4</sub>	asi	$7.5 \times 10^{-3}$	2.12
rof	HF	F-	, lfar	$3.5 \times 10^{-4}$	3.45
orde	CH₃COOH	CH₃COO⁻	rde	1.8 × 10 <sup>-5</sup>	4.7
mg (	H <sub>2</sub> S	HS <sup>-</sup>	60	1.0 × 10 <sup>-7</sup>	7.0
easi	NH <sup>‡</sup>	NH <sub>3</sub>	easi	$5.6 \times 10^{-10}$	9. <b>3</b>
Inc	HCN	CNT.	Incr	$4.0 \times 10^{-10}$	9. <b>4</b>
	H <sub>2</sub> O	OH-	Table to the same state of the	$1.0 \times 10^{-14}$	14.0
	CH₃OH	CH <sub>3</sub> O⁻		Very small	Large
	NH <sub>3</sub>	NH <sub>2</sub>		Very small	Large

**Note:** In order to avoid writing negative powers of 10,  $K_a$  or  $K_b$  are generally converted into  $pK_a$  ( $-\log_{10} K_a$ ) or  $pK_b$  ( $-\log_{10} K_b$ ) respectively. Smaller the value of  $pK_a$  indicates the stronger acids.

The strength of an acid also depends upon the solvent. The acids  $HClO_4$ , HCl,  $H_2SO_4$  and  $HNO_3$  which have nearly same strength in water, will be in the order of,

$$HClO_4 > H_2SO_4 > HCl > HNO_3$$

in acetic acid, since the proton accepting tendency of acetic acid is much weaker than water. HCl acts as a stronger acid in NH<sub>3</sub>, weak acid in CH<sub>3</sub>COOH, neutral in benzene and a weak base in HF.

#### Levelling and Differentiating Effect

Water is a strong base as it has a great tendency to accept protons from strong acids. Thus, all strong acids such as HClO<sub>4</sub>, HBr, HI, H<sub>2</sub>SO<sub>4</sub>, etc., almost completely react with water and they appear to be equally strong in water. **This effect of water and other strong bases to level all the strong acids to the same strength is known as levelling effect.** Consequently, no acid significantly stronger than H<sub>3</sub>O<sup>+</sup> can survive in water. So, relative strengths of strong acids cannot be determined in water.

An analogous limit can be found for bases in water. Any base *B* that is strong enough to undergo complete protonation by donation from water, leaving OH<sup>-</sup> ions in solution in place of every *B* molecule added, will be levelled. The OH<sup>-</sup> ion is the strongest base that can exist in water because anything stronger immediately forms OH<sup>-</sup> ions by reaction with water. Thus, alkali metal amides and methanides cannot be studied in water because both anions generate OH<sup>-</sup> ions quantitatively and are fully protonated to NH<sub>3</sub> and CH<sub>4</sub>.

$$KNH_2 + H_2O \Longrightarrow K^+(aq) + OH^-(aq) + NH_3(aq)$$
  
 $LiCH_3 + H_2O \Longrightarrow Li^+(aq) + OH^-(aq) + CH_4(q)$ 

When strong acids are dissolved in a weak acid or a weak base, all are not equally ionised and their relative strengths can be differentiated. It is called **differentiating effect**. For example, acetic acid instead of water as a solvent can be used for the grading of strong acids. This is because of the poor proton accepting character of acetic acid. The acidic character of a number of acids when dissolved in glacial acetic acid (solvent) has been determined by measuring degree of dissociation. The acidic character has been found to be in the following order:

$$HClO_4 > HBr > H_2SO_4 > HCl > HNO_3$$
.

#### Limitations

- (i) A substance is termed as an acid or base if it reacts with some other substance, *i.e.*, if it donates proton to other substance, it is an acid and if it accepts proton from other substance, it is a base.
- (ii) There are number of acid-base reactions in which no proton transfer takes place, e.g.,

$$SO_2 + SO_2 \Longrightarrow SO^{2+} + SO_3^{2-}$$
  
 $Acid_I \quad Base_{II} \quad Acid_{II} \quad Base_{II}$ 

Thus, the protonic definition cannot be used to explain the reactions occurring in non-protonic solvents such as  $COCl_2$ ,  $SO_2$ ,  $N_2O_4$ , etc.

**Example 1.** *Identify the Bronsted acid and its conjugate base in the following :* 

(a) 
$$PO_A^{3-} + H_2O \Longrightarrow HPO_A^{2-} + OH^{-}$$

(b) 
$$H_2Fe(CO)_4 + CH_3OH \rightleftharpoons [HFe(CO)_4]^- + CH_3OH_2^+$$

(c) 
$$HNO_3 + H_2O \rightleftharpoons H_3O^+ + NO_3^-$$

$$(d) NH_3 + H_2S \Longrightarrow NH_4^+ + HS^-$$

#### Solution:

In (a),  $H_2O$  transfers a proton to  $PO_4^{3-}$ , thus,  $H_2O$  is Bronsted acid and  $OH^-$  is its conjugate base. In (b),  $H_2Fe(CO)_4$  is an acid as it donates a proton to  $CH_3OH$ . Its conjugate base is  $[HFe(CO)_4]^-$ . In (c),  $HNO_3$  is an acid as it donates a proton to  $H_2O$ .  $NO_3^-$  is its conjugate base.

In (d),  $H_2S$  is an acid as it transfers a proton to  $NH_3$ . Its conjugate base is  $HS^-$ .

**Example 2.** A bottle is marked with 'Acid' pH = 5. Whether the acid is strong or weak? Explain.

#### Solution:

It cannot be predicted on the basis of pH alone whether the acid is strong or weak. pH depends on concentration.

**Example 3.** (a) Liquid  $NH_3$  like water is an amphiproti solvent. Write the equation for the autoionisation of  $NH_3$ .

(b) Aniline is a weak organic base in aqueous solution. Suggest a solvent in which aniline would become a stronger base.

#### Solution:

- (a)  $NH_3 + NH_3 \rightleftharpoons NH_4^+ + NH_2^-$
- (b) Any solvent which has appreciably stronger acidic properties than water would render aniline as a stronger base. Acetic acid is one such solvent.

### 3.4 LEWIS CONCEPT

A more general and fundamental concept of acid-base behaviour was proposed by G.N. Lewis in 1923 (the same year in which Bronsted concept was introduced). However, the concept became influential only in 1930 onwards. According to this concept, a base is a substance which can furnish a pair of electrons to form a coordinate bond whereas an acid is a substance which can accept a pair of electrons. A Lewis acid is a substance that acts as an electron acceptor or electrophile while a Lewis base is a substance that acts as an electron donor or nucleophile. Neutralisation reaction involves the formation of a coordinate bond.

A simple example of an acid-base is the reaction between a proton and a hydroxyl ion.

$$H^+ + : O: H^- \longrightarrow H: O: H$$
Acid Base

Some other examples are:

$$H_3N$$
: +  $BF_3 = H_3N \rightarrow BF_3$ 
 $Base$ 
Acid

 $H^+$  + :N $H_3 = [H \leftarrow NH_3]^+$ 
Acid

 $BF_3$  + :F: = [:F \to BF\_3]

According to Lewis concept, the given species can act as Lewis acids:

(i) Molecules in which the central atom has incomplete octet: Lewis acids are electron deficient molecules such as BF<sub>3</sub>, AlCl<sub>3</sub>, GaCl<sub>3</sub>, etc.

$$H_3N: + AlCl_3 \longrightarrow H_3N \longrightarrow AlCl_3$$

(ii) Molecules in which the central arom has empty *d*-orbitals: The central atom of the halides such as  $SiX_4$ ,  $GeX_4$ ,  $TiCl_4$ ,  $SnCl_4$ ,  $PX_3$ ,  $PF_5$ ,  $SF_4$ ,  $SeF_4$ ,  $TeCl_4$ , etc., have vacant *d*-orbitals. These can, therefore, accept an electron pair and act as Lewis acids.

$$SiF_4 + 2:F:^- \longrightarrow [SiF_6]^{2-}$$
  
Lewis acid Lewis base Complex

(iii) Simple cations: All cations are expected to act as Lewis acids since they are electron deficient in nature. However, cations such as  $Na^+$ ,  $K^+$ ,  $Ca^{2+}$ , etc., (inert gas configuration) have a very little tendency to accept electrons, while the cations like  $H^+$ ,  $Ag^+$ ,  $Fe^{3+}$ ,  $Cu^{2+}$ , etc., have greater tendency to accept electrons and, therefore, act as Lewis acids.

$$Ag^+ + 2:NH_3 \longrightarrow [H_3N \rightarrow Ag \leftarrow NH_3]^+$$
  
 $Fe^{2+} + 6CN^- \longrightarrow [Fe(CN)_6]^{4-}$ 

(iv) Molecules having a multiple bond between atoms of dissimilar electronegativity: Typical examples of molecules belonging to this class of Lewis acids are  $CO_2$ ,  $SO_2$  and  $SO_3$ . Under the influence of attacking Lewis base, one  $\pi$ -electron pair will be shifted towards the more negative atom.

$$OH$$

$$C = O + OH^{-} \longrightarrow -O - C = O \text{ or } HCO_{3}^{-}$$

**(v) Elements with an electron sextet:** Oxygen and sulphur atoms contain six electrons in their valency shell and can accept a lone pair of electrons and act as Lewis acids.

The following species can act as Lewis bases:

(i) Neutral species having at least one lone pair of electrons: For example, ammonia, amines, alcohols, etc., act as Lewis bases as they contain a pair of electrons.

:NH<sub>3</sub>, 
$$R$$
— $\dot{N}$ H<sub>2</sub>,  $R$ — $\dot{O}$ —H, H— $\dot{O}$ —H,  $R$ — $\dot{O}$ — $R$ 

(ii) Negatively charged species or simple anions: For example, chloride, cyanide, hydroxide ions, etc., act as Lewis bases.

(iii) Multiple bonded compounds: The compounds which form coordination compounds with transition metals such as CO, NO, ethylene, acetylene, etc., can act as Lewis bases.

$$CH_2 = CH_2 + Ag^+ \longrightarrow \begin{bmatrix} CH_2 - CH_2 \\ Ag \end{bmatrix}^+$$

It may be noted that all Bronsted bases are also Lewis bases but all Lewis acids are not Bronsted acids.

#### Limitations of Lewis Concept

- (i) Lewis theory fails to explain the relative strength of acids and bases as different types of reactions are involved.
- (ii) Acids such as HCl, H<sub>2</sub>SO<sub>4</sub> do not form coordinate bonds with bases.
- (iii) All acid-base reactions are fast. However, the formation of coordinate bond is very slow in certain cases.

**Example 4.** (a) What is the Lewis acid and base in the following reaction?

$$2NH_3(aq) + Ag^{\dagger}(aq) \longrightarrow [Ag(NH_3)_2]^{\dagger}(aq)$$

- (b) What allows ethoxyethane to behave as a Lewis base?
- (c) Whether aluminium trichloride is a Lewis acid or a base or both?

#### Solution:

- (a) The silver ion accepts the lone pairs from ammonia. Therefore, Ag<sup>+</sup> is a Lewis acid and ammonia a Lewis base.
- (b) The ether has two lone pairs on the oxygen like water.
- (c) AlCl<sub>3</sub> acts both as a Lewis acid and base, *i.e.*, aluminium atom is the Lewis acid and chlorine the Lewis base. Due to this reason it forms dimer, Al<sub>2</sub>Cl<sub>6</sub>.

**Example 5.** (a) How do you account for the formation of  $S_2O_3^{2-}$  from  $SO_3^{2-}$  and S in terms of Lewis acid theory?

(b) Whether the following reaction is Lewis acid-base reaction or not?

$$Ca + S \longrightarrow Ca^{2+} + S^{2-}$$

#### Solution:

(a) A sulphur atom is electron deficient and can thus be regarded as an acid.  $SO_3^{2-}$  acts as a base.

(b) The reaction is not a Lewis acid-base reaction as it does not form a coordinate bond.

### 3.5. THE LUX-FLOOD CONCEPT

The concept proposed by Lux (1939) and extended by Flood (1947) to explain acid-base reactions in terms of the oxide ion. According to this concept, a base is any substance which gives up oxide ions and an acid is any substance which gains oxide ions.

$$SO_4^{2-} \Longrightarrow SO_3 + O^{2-}$$

$$Base \qquad Acid$$

$$CaO \Longrightarrow Ca^{2+} + O^{2-}$$

$$Base \qquad Acid$$

$$SiO_2 + O^{2-} \Longrightarrow SiO_3^{2-}$$

$$Acid \qquad Base$$

Thus, acids are the oxide ion acceptors, while bases are the oxide ion donors.

The following reactions, thus, involve CaO, PbO as bases and  $SiO_2$ ,  $SO_3$  as acidic oxides which react together to form salts respectively.

$$\begin{array}{cccc} \text{CaO} & + & \text{SiO}_2 & \longrightarrow & \text{CaSiO}_3 \\ \text{Base} & & \text{Acid} & & & \text{Salt} \\ \text{PbO} & + & \text{SO}_3 & \longrightarrow & \text{PbSO}_4 \\ \text{Base} & & \text{Acid} & & & \text{Salt} \\ \end{array}$$

Substances are termed amphoteric if they show a tendency of losing as well as accepting an oxide ion.

$$ZnO + O^{2-} \Longrightarrow ZnO_2^{2-}$$
;  $ZnO \Longrightarrow Zn^{2+} + O^{2-}$   
 $Al_2O_3 + O^{2-} \Longrightarrow 2AlO_2^{-}$ ;  $Al_2O_3 \Longrightarrow 2Al^{3+} + 3O^{2-}$ 

The Lux-Flood concept can be extended to include transfer of any anion, for example, halide, sulphide, etc.

$$3NaF + AlF_3 \xrightarrow{\text{High temp.}} 3Na^+ + AlF_6^{3-}$$

### 3.6 USANOVICH CONCEPT

This concept is an extension of Lewis concept. According to this concept, an acid is any chemical species which reacts with bases, gives up cations or accepts anions or electrons and a base is any chemical species which reacts with acids, gives up anions or accepts cations or donates electrons. Besides, Arrhenius, Bronsted-Lowry or Lewis acids and bases, this concept includes all the oxidising agents as acids

and reducing agent as bases. Some examples of acid-base reactions in terms of this concept are given below:

Acid	Base	Salt	Justification
Cl <sub>2</sub> +	2K →	2KCl	K loses an electron while Cl gains an electron.
SO <sub>3</sub> +	CaO	CaSO <sub>4</sub>	CaO yields $O^{2-}$ and $SO_3$ accepts $O^{2-}$ .
As <sub>2</sub> S <sub>5</sub> +	-3(NH <sub>4</sub> ) <sub>2</sub> S -	$\longrightarrow$ 2(NH <sub>4</sub> ) <sub>3</sub> AsS	4 $(NH_4)_2S$ loses $S^2$ ions while $As_2S_5$ gains $S^2$ ions.
Fe(CN)	2+4KCN -	$\longrightarrow K_4 \text{Fe}(CN)_6$	Fe(CN) <sub>2</sub> combines with CN <sup>-</sup> ions given by KCN.

It is the most general concept out of the concepts of acid-base so far given. The concept is undoubtedly too broad that nearly all the chemical reactions fall into acid-base category.

### 3.7 HARD AND SOFT ACIDS AND BASES

All the Lewis acids and bases are classified as hard and soft acids and bases. It was proposed by **Pearson** in 1963 in order to explain the stability of the complexes formed by the combination of a Lewis acid and a Lewis base.

**Soft bases** have donor atoms which are easily polarised and have low electronegativity. The **hard bases** have properties opposite to those of the soft bases, *i.e.*, hard bases have donor atom with low polarizabilities and high electronegativity. Within a group in the periodic table softness increases with increasing size of the donor atom.

**Hard bases:**  $H_2O$ ,  $OH^-$ ,  $F^-$ ,  $CH_3COO^-$ ,  $PO_4^{3-}$ ,  $SO_4^{2-}$ ,  $CI^-$ ,  $CO_3^{2-}$ ,  $CIO_4^-$ ,  $NO_3^-$ , ROH,  $RO^-$ ,  $R_2O$ ,  $NH_3$ ,  $RN_2$ ,  $N_2H_4$ .

**Soft bases:**  $R_2$ S, RSH, RS $^-$ ,  $I^-$ , SCN $^-$ ,  $S_2$ O $_3^{2-}$ ,  $R_3$ P,  $R_3$ As,  $(RO)_3$ P, CN $^-$ , RNC, CO,  $C_2$ H $_4$ ,  $C_6$ H $_6$ ,  $H^-$ ,  $R^-$ .

**Border line:**  $C_6H_5NH_2$ ,  $C_5H_5N$ ,  $Br^-$ ,  $NO_2^-$ ,  $SO_3^{2-}$ ,  $N_3^-$ .

**Soft acids** are those which possess acceptor atoms, large in size, of low positive charge, have high polarizability and low electronegativity and do not have noble gas configuration. **Hard acids** are those in which acceptor atoms have small size, high electronegativity, low polarizability and possess noble gas configuration.

**Hard acids:** H<sup>+</sup>, Li<sup>+</sup>, Na<sup>+</sup>, K<sup>+</sup>, Be<sup>2+</sup>, Ca<sup>2+</sup>, Sr<sup>2+</sup>, Mn<sup>2+</sup>, Al<sup>3+</sup>, Ga<sup>3+</sup>, In<sup>3+</sup>, La<sup>3+</sup>, CO<sup>3+</sup>, Cr<sup>3+</sup>, Fe<sup>3+</sup>, Ti<sup>4+</sup>, etc.

**Soft acids:** Cu<sup>+</sup>, Ag<sup>+</sup>, Au<sup>+</sup>, Te<sup>+</sup>, Hg<sup>+</sup>, Pd<sup>2+</sup>, Cd<sup>2+</sup>, Pt<sup>2+</sup>, Hg<sup>2+</sup>, GaCl<sub>3</sub>, I<sup>+</sup>, Br<sup>+</sup>, I<sub>2</sub>, Br<sub>2</sub>, etc.

**Border line**: Fe<sup>2+</sup>, CO<sup>2+</sup>, Ni<sup>2+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup>, Pb<sup>2+</sup>, Sn<sup>2+</sup>, Sb<sup>3+</sup>, SO<sub>2</sub>, etc.

The bonding between hard acids and hard bases are predominantly ionic whereas the soft-soft interactions give largely covalent compounds. Hard acids have vacant orbitals and can accept  $\sigma$ -electrons while hard bases with filled outer

valence shell orbitals, can donate the  $\sigma$ -pair of electrons. For weak acids and weak bases,  $\pi$ -bonding seems to be important. The compounds between hard acids and hard bases and between soft acids and soft bases are stable.

# 3.89 SOME GENERAL TRENDS IN ACIDIC AND BASIC PROPERTIES (On the basis of

Arrhenius and Bronsted-Lowry concepts)

In order to analyse the relationship between molecular structure, the acids are divided into two types:

- (i) Covalent hydrides: In these the proton is directly attached with the central atom of the molecule. Examples are: HX(X = F, Cl, Br, I),  $H_2O$ ,  $CH_4$ ,  $H_2S$ , etc. These are also called hydracids or hydroacids.
- (ii) Oxy-acids: In these the proton is attached to an oxygen atom, the later being bonded to the central atom. Examples are: H<sub>2</sub>SO<sub>3</sub>, HNO<sub>3</sub>, H<sub>2</sub>SO<sub>4</sub>, HClO<sub>4</sub>, etc.

### (i) Covalent hydrides:

Two factors influence the acid strength of the hydride of an element: The electronegativity of the element and the atomic size of the element. The first of these factors is best understood by comparing the hydrides of the elements of a period of the periodic table. The second is important when group comparisons of the periodic table are made.

(a) Hydrides of the elements of a period: The acid strengths of the hydrides of the elements of a period increase from left to right in the same order as electronegativity increases. Highly electronegative element withdraws electrons from the hydrogen easily and facilitate the release of hydrogen as proton. The electronegativities of the following second and third period elements fall in the order:

$$N < O < F$$
 and  $P < S < C1$ 

The acid strength of the hydrides increases in the same order:

$$NH_3 < H_2O < HF$$
 and  $PH_3 < H_2S < HC1$ 

The increase in acidic nature is also due to the fact that the stability of their conjugate bases increases in the order:

$$NH_2^- < OH^- < F^-$$

The increase in acidic properties is supported by successive increase in the dissociation constant.

$$NH_3(=10^{-35}) < H_2O(=10^{-14}) < HF(=10^{-4})$$

**(b) Hydrides of the elements of a group:** The acidity of the hydrides of the elements of a group increases with increasing size of the central atom. For example in the hydrides of VIA or XVI group and VIIA or XVII group, the acidic nature increases as the atomic number of the central element increases.

$$H_2O < H_2S < H_2Se < H_2Te$$

and HF < HCl < HBr < HI

The two factors which influence acid strength work against each other in these hydrides. The effect of atomic size outweighs the electronegativity effect. A proton is more easily removed from a hydride in which the central atom is larger than from one in which the central atom is small. The charge density on the conjugate base is in the order:

$$O^{2-} > S^{2-} > Se^{2-} > Te^{2-}$$
  
and  $F^- > Cl^- > Br^- > l^-$ 

Greater charge density on the conjugate base will result in greater proton attraction.

The acidic nature of the hydrides of VIIA group elements is also explained by the fact that bond energies decrease.

$$H - F > H - Cl > H - Br > H - I$$
135 kcal mol<sup>-1</sup> 103 kcal mol<sup>-1</sup> 88 kcal mol<sup>-1</sup> 71 kcal mol<sup>-1</sup>

Due to large electronegativity, hydrogen bonding exists in the hydrides of oxygen and fluorine which also decreases their acid strength.

In the hydrides of the elements having nearly the same electronegativity, the acidic nature increases as the size of the central element increases. C, S and I possess same electronegativity, the acidic nature follows the following order:

$$CH_4 < H_2S < HI$$

as the size increases from carbon to iodine.

#### 🕍 (ii) Oxy-acids:

In oxy-acids, the proton is attached to oxygen atom which is linked to the central atom.

$$H \stackrel{a}{\longrightarrow} O \stackrel{b}{\longrightarrow} Z$$

The main factors which affect the strength of an oxy-acid are: (a) the size of the central atom, (b) the electronegativity of the central atom and (c) the number of other electronegative atoms attached to the central atom.

Smaller the size and greater the electronegativity of Z make the oxy-acid stronger. These factors will shift the electron pair between Z and O towards Z and this displacement will in turn cause a shifting of electron pair between oxygen and hydrogen towards oxygen. Thus, O—H bond is weakened and proton is easily released. In the series,

The electronegativity increases and size decreases of the central element. Same trend is observed in the oxy-acids of different elements in the same oxidation state  $HClO_4 > HBrO_4 > HIO_4$ .

Greater the number of negative atoms present in the oxyacid make the acid stronger. In general, the strengths of acids that have general formula,

$$(HO)_m ZO_n$$

can be related to the value of n.

If n = 0, the acid is very weak, HOCl, (HO)<sub>3</sub>B, (HO)<sub>4</sub>Si. If n = 1, the acid is weak, HOClO, HONO, (HO)<sub>2</sub>SO, (HO)<sub>3</sub>PO.

If n = 2, the acid is strong, HOClO<sub>2</sub>, HONO<sub>2</sub>, (HO)<sub>2</sub>SO<sub>2</sub>. If n = 3, the acid is very strong, HOClO<sub>3</sub>, HOIO<sub>3</sub>.

The negative atoms draw electrons away from the Z-atom and make it more positive. The Z-atom, therefore, becomes more effective in withdrawing electron density away from the oxygen atom that is bonded to hydrogen. In turn, the electrons of H—O bond are drawn more strongly away from the H-atom. The net effect makes it easier for the proton release and increases the acid strength.

This effect is illustrated by the following series of acids:

**Note:** In the above examples, it is evident that strength of the acid increases as the oxidation number of the central atom increases. However, this rule fails in oxy-acids of phosphorus,

$$H_3^{+1}PO_2$$
 ;  $H_3^{+3}PO_3$  ;  $H_3^{+5}PO_4$ 

as all are weak acids, *i.e.*, about the equal strength. Thus, prediction on the basis of oxidation number is **incorrect**. Formal charge on the central atom gives more reliable prediction. The strength of the acid increases as the formal charge on the central atom increases.

Formal charge = Group number – number of bonds – number of unshared electrons.

As the formal charge is same, all the above oxy-acids of phosphorus are nearly of equal strength.

#### Strength of Bases

(a) Among alkali and alkaline earth metals oxides and hydroxides, the basic nature increases as the size of the central atom increases, *i.e.*, electropositive nature increases.

$$CsOH > RbOH > KOH > NaOH > LiOH$$
  
 $Ba(OH)_2 > Sr(OH)_2 > Ca(OH)_2 > Mg(OH)_2 > Be(OH)_2$ 

(b) Among the hydrides of the same group, the basic nature decreases with increase in the size of central atom as the tendency to accept proton decreases due to decrease in electron density (or ability to donate the electron pair decreases).

$$NH_3 > PH_3 > AsH_3 > SbH_3 > BiH_3$$
Basic Less basic Neutral

(c) The larger the size of the atom holding the unshared electrons, the lesser is the availability of the electrons, *i.e.*, the basic strength of halide ions follow the following order:

(d) The basic nature of a substance decreases with the increase of the electronegativity of the atom holding the lone pair of electrons, *i.e.*, the tendency to donate the electron pair to proton decreases with increase of electronegativity.

$$:NH_3 > H_2O: > HF:$$

(e) The presence of a positive charge on the atom holding the lone pair decreases the base strength while a negative charge increases the base strength.

$$:OH>H-O-H>H_3O^{\dagger}:$$

(f) Base strength increases with decrease in oxidation state of the central atom.

$$NH_3 > N_2H_4$$
 ;  $PH_3 > P_2H_4$  Oxid. Number -3 -2 -3 -2

#### **Amphoterism**

Similarly,

Substances which behave as bases towards strong acids and acids towards strong bases are called **amphoteric** and the phenomenon as **amphoterism**. Some metal oxides and hydroxides are amphoteric. For example, ZnO and Zn(OH)<sub>2</sub>, Al<sub>2</sub>O<sub>3</sub> and Al(OH)<sub>3</sub>, SnO and Sn(OH)<sub>2</sub>, PbO and Pb(OH)<sub>2</sub>, Cr<sub>2</sub>O<sub>3</sub> and Cr(OH)<sub>3</sub> are amphoteric in nature.

$$ZnO + 2HCl \longrightarrow ZnCl_2 + H_2O$$
  
 $ZnO + 2NaOH \longrightarrow Na_2ZnO_2 + H_2O$   
 $Sn(OH)_2 + 2HCl \longrightarrow SnCl_2 + 2H_2O$   
 $Sn(OH)_2 + 2NaOH \longrightarrow Na_2SnO_2 + 2H_2O$ 

The salts of Zn<sup>2+</sup>, Sn<sup>2+</sup>, Pb<sup>2+</sup>, Al<sup>3+</sup> and Cr<sup>3+</sup> dissolve in excess of NaOH solution due to formation of hydroxide first.

$$ZnCl_2 + 2NaOH \longrightarrow Zn(OH)_2 + 2NaCl$$
  
 $Zn(OH)_2 + 2NaOH \longrightarrow Na_2ZnO_2 + 2H_2O$ 

**Example 6.** Explain on the basis of SHAB principle,

- (a)  $Ag(CN)_2^-$  is stable while  $AgCl_2^-$  is unstable.
- (b) The alkaline earth metals are found in nature as carbonates and sulphates whereas mercury and silver are found as sulphides.

#### Solution:

(a)  $Ag^+$  is a soft acid,  $CN^-$  is a soft base while  $Cl^-$  is a hard base. Therefore,  $Ag(CN)_2^-$  (soft acid + soft base) is a stable complex while  $AgCl_2^-$  (soft acid + hard base) is an unstable complex.

(b) The ions  $Ca^{2+}$ ,  $Mg^{2+}$ ,  $Ba^{2+}$ , etc., are hard acids while  $SO_4^{2-}$  and  $CO_3^{2-}$  ions are also hard bases. Since compounds of hard acids and hard bases are stable, alkaline earth metals are found in nature as sulphates and carbonates. However,  $Hg^{2+}$  and  $Ag^+$  ions are soft acids. They combine with soft bases such as  $S^{2-}$  to form stable compounds.

#### **Example 7.** Explain the following:

- (a) Br ion is a Lewis as well as Bronsted base.
- (b) NH<sub>3</sub> is a Lewis as well as Bronsted base.
- (c) BF<sub>3</sub> is a Lewis acid but not a Bronsted acid.

#### Solution:

- (a) Br ion contains lone pair of electrons which it can donate. Hence, it acts as a Lewis base. Br can accept proton and hence, it acts as a Bronsted base.
  - (b) NH<sub>3</sub> acts as a Lewis base as the nitrogen possesses a lone pair of electrons which it can donate (H<sub>3</sub>N → BF<sub>3</sub>). It can combine with H<sup>+</sup> to form ammonium, NH<sub>4</sub><sup>+</sup> ion. Hence, it is a Bronsted base.
  - (c) BF<sub>3</sub> acts as a Lewis acid as it is an electron pair acceptor (H<sub>3</sub>N: + BF<sub>3</sub> → H<sub>3</sub>N → BF<sub>3</sub>). BF<sub>3</sub> does not possess the tendency to lose a proton, hence it is not a Bronsted acid.

# SUMMARY AND IMPORTANT POINTS TO REMEMBER

- 1. The word acid is a Latin word-acidus meaning sour.
- Liebig, in 1830, defined acid as a compound which contains one or more hydrogen atoms replaceable partially or completely by a metal or a positive radical to produce a salt
- 3. According to Arrhenius concept, all substances which give H<sup>+</sup> ions when dissolved in water are called acids while those which ionise in water to furnish OH<sup>-</sup> ions are called bases. The reaction between an acid and a base is termed neutralisation, i.e., neutralisation involves the reaction between H<sup>+</sup> and OH<sup>-</sup> ions to form water.

#### Limitations

- It is applicable to aqueous solutions only, i.e., water is necessary to explain the acidic or basic properties of the substances.
- (ii) It fails to explain acidic properties of non-protic compounds such as SO<sub>2</sub>, P<sub>2</sub>O<sub>5</sub>, etc.
- (iii) It fails to explain the basic nature of compounds like NH<sub>3</sub>, Na<sub>2</sub>CO<sub>3</sub>, etc.
- (iv) It fails to explain the acidic nature of salts like AlCl<sub>3</sub> in aqueous solution.
- 4. Modified Arrhenius concept rectifies most of the limitations. Water is a weak electrolyte and neutral in nature, i.e., [H<sub>3</sub>O<sup>+</sup>] = [OH<sup>-</sup>].

The substances which increase the concentration of  $\mathrm{H_3O^+}$  ions in water act as acids while those which increase the concentration of  $\mathrm{OH^-}$  ions act as bases.  $\mathrm{SO_2}$  is thus an acid and  $\mathrm{NH_3}$  is a base.

$$SO_2 + H_2O \rightleftharpoons H_2SO_3 \rightleftharpoons H_3O^+ + HSO_3^-$$
  
 $NH_3 + H_2O \rightleftharpoons NH_4OH \rightleftharpoons NH_4^+ + OH^-$ 

- The strength of an acid or a base in Arrhenius concept is based on the extent of ionisation, i.e., on the equilibrium constant of an acid, K<sub>a</sub>, and on the equilibrium constant of a base, K<sub>b</sub>.
- 6. According to Bronsted-Lowry concept, a substance is known as an acid if it can donate a proton and as a base if it can accept a proton. Acids are proton donors (protogenic) and bases are proton acceptors (protophilic).

Chemical species that differ in composition only by proton are called a conjugate pair.

Acid 
$$\rightleftharpoons$$
 H<sup>+</sup> + Base

Every acid has its conjugate base. If acid is strong, its conjugate base is strong and *vice-versa*. An acid base reaction involves two conjugate pairs, *i.e.*, when acid reacts with a base another acid and base are formed.

H<sub>2</sub>O can act either as an acid or a base (amphiprotic).

- **8.** HCO<sub>3</sub>, HSO<sub>4</sub>, H<sub>2</sub>PO<sub>4</sub>, HPO<sub>4</sub>, H<sub>2</sub>PO<sub>3</sub> and HSO<sub>3</sub> are amphiprotic in nature.
- **9.** Solvents which neither donate nor accept protons, *e.g.*, benzene, carbon tetrachloride, carbon disulphide, etc., are called aprotic solvents.
- 10. The strength of an acid depends upon its tendency to lose its proton and the strength of the base depends upon its tendency to gain the proton.

$$HA + H_2O \rightleftharpoons H_3O^+ + A^- : B + H_2O \rightleftharpoons H^+B + OH^-$$

$$K_a = \frac{[H_3O^+][A^-]}{[HA]}$$
  $K_b = \frac{[H^+B][OH^-]}{[B]}$ 

Larger the value of  $K_a$  indicates that the acid is stronger in nature.

Larger the value of  $K_b$  indicates that the base is stronger in nature.

The strength of an acid also depends on the solvent. The acids  $HClO_4$ , HCl,  $H_2SO_4$  and  $HNO_3$  which have nearly same strength in water, will be in the order of :

$$HClO_4 > H_2SO_4 > HCl > HNO_3$$

in acetic acid. HCl acts as a stronger acid in NH<sub>3</sub>, weak acid in acetic acid, neutral in benzene and weak base in HF. In order to avoid writing negative powers,  $K_a$  or  $K_b$  are generally converted into p $K_a$  ( $-\log_{10} K_a$ ) or p $K_b$  ( $-\log_{10} K_b$ ) respectively. Smaller the value of p $K_a$  indicates the stronger acid.

11. Any species, that is an acid by Arrhenius concept remains an acid in the Bronsted-Lowry concept. The same is true for

bases. Certain species which do not contain  $OH^-$  group which are not regarded as bases by Arrhenius concept such as  $HCO_3$ ,  $H_2PO_4$ , etc., are regarded as bases by Bronsted-Lowry concept.

12. According to Lewis concept, a base is a substance which can furnish a pair of electrons to form a coordinate bond whereas an acid is a substance which can accept a pair of electrons. Lewis acid is an electron acceptor, i.e., electrophile while a Lewis base is an electron donor or nucleophile. Lewis acid is electron deficient while Lewis base is electron rich species (lone pair of electrons).

The following species can act as Lewis acids:

- (i) Molecules in which central atom has incomplete octet such as: BF<sub>3</sub>, AlCl<sub>3</sub>, GaCl<sub>3</sub>, etc.
- (ii) Molecules in which central atom has empty d-orbitals such as : SiX<sub>4</sub>, SnCl<sub>4</sub>, PF<sub>5</sub>, SF<sub>4</sub>, PX<sub>3</sub>, etc.
- (iii) Simple cations such as : H<sup>+</sup>, Ag<sup>+</sup>, Fe<sup>3+</sup>, Cu<sup>2+</sup>, etc., have a tendency to accept electrons.
- (iv) Molecules having a multiple bond between atoms of dissimilar electronegativity such as: CO<sub>2</sub>, SO<sub>2</sub>, SO<sub>3</sub>, etc.
- (v) Elements with an electron sextet such as oxygen and sulphur atoms.

The following species can act as Lewis bases:

- (i) Neutral species having at least one lone pair of electrons such as: NH<sub>3</sub>, R—NH<sub>2</sub>, R—O—H, etc.
- (ii) Negatively charged species or simple anions such as :  $Cl^-$ ,  $CN^-$ ,  $OH^-$ , etc.
- (iii) Multiple bonded compounds such as : CO, NO, C<sub>2</sub>H<sub>4</sub>, C<sub>2</sub>H<sub>2</sub>, etc.

It may be noted that all Bronsted bases are also Lewis bases but all Lewis acids are not Bronsted acids.

13. According to Lux-Flood concept, a base is any substance which gives up oxide ions and an acid is any substance which gains oxide ions. Thus, acids are the oxide acceptors, while bases are oxide ion donors.

$$SO_4^{2-} \iff SO_3 + O^{2-}$$
 ;  $SiO_2 + O^{2-} \iff SiO_3^{2-}$   
Base Acid Acid Base

- 14. According to Usanovich concept, an acid is any chemical species which reacts with bases, gives up cations or accepts anions or electrons while a base is any chemical species which reacts with acids, gives up anions or accepts cations or donates electrons. This concept is an extension of Lewis concept. This concept regards all oxidising agents as acids and reducing agents as bases.
- 15. All the Lewis acids and bases are classified as hard and soft acids and bases. It was proposed by Pearson in 1963. Soft bases have donor atoms which are easily polarised and have low electronegativity such as: RSH, I<sup>-</sup>, R<sub>3</sub>P, CN<sup>-</sup>, etc.

Hard bases have donor atoms which have high electronegativity and low polarizabilities such as :  $H_2O$ ,  $OH^-$ ,  $F^-$ ,  $CI^-$ ,  $CO_3^{2-}$ ,  $NH_3$ , etc.

**Soft acids** are those which have acceptor atoms, large in size, low electronegativity, low positive charge and do not have noble gas configuration. These possess high polarizability. The examples are:  $Ag^+$ ,  $Au^+$ ,  $Cd^{2+}$ ,  $Sn^{2+}$ ,  $Hg^{2+}$  and  $I^+$ , etc.

Hard acids are those in which atoms have small size, high electronegativity, low polarizability and possess noble gas configuration. The examples are :  $H^+$ ,  $Li^+$ ,  $Na^+$ ,  $Ca^{2+}$ ,  $Mn^{2+}$ ,  $Al^{3+}$  and  $Ti^{4+}$ , etc.

The bonding between hard acids and hard bases are predominantly ionic whereas the soft-soft interactions give largely covalent compounds. All these compounds are stable.

#### 16. Trends in acidic and basic properties:

Acids are divided into two types:

- Covalent hydrides: In these, proton is directly attached to the central atom of the molecule.
- (ii) Oxy-acids: In these, proton is attached to an oxygen atom, the later being bonded to the central atom.
- Covalent hydrides: Two factors influence the acid strength, the electronegativity and the size of the central atom.
  - (a) The acid strength of the hydrides of the elements of a period increases from left to right as the electronegativity increases. Highly electronegative element withdraws the electrons from the hydrogen easily and facilitate the release of hydrogen as proton.

$$NH_3 < H_2O < HF$$
 and  $PH_3 < H_2S < HCl$   
Acidic nature increases.

(b) The acid strength of the hydrides of the elements of a group increases with increasing size of the central atom.

$$H_2O < H_2S < H_2Se < H_2Te$$
  
 $HF < HCl < HBr < HI$ 

Acid strength increases as the size increases.

- 2. Oxy-acids: The main factors which affect the acid strength of an oxy-acid are:
  - (a) The size of central atom,
  - (b) The -electronegativity,
  - (c) The number of other electronegative atoms attached to the central atom.

Smaller the size and greater the electronegativity of central atom make the oxy-acid stronger. These factors shift the electron pair of the bond of oxygen towards central atom and this displacement will in turn cause a shifting of electron pair between oxygen and hydrogen towards oxygen. Thus, O—H bond is weakened and proton is easily released.

oxy-acid make the acid stronger. In general, the strengths of the acids that have general formula,

$$(HO)_m ZO_n$$

can be related to the value of n.

If n = 0, the acid is very weak Example HOCl

If n = 1, the acid is weak Example HOClO

If n = 2, the acid is strong Example HOClO<sub>2</sub>

If n = 3, the acid is very strong Example HOClO<sub>3</sub>

[Formal charge on the central atom gives more reliable prediction about the strength of acid. The strength increases as the formal charge on the central atom increases. In the case of oxy-acids of phosphorus, the acid strength of the following oxy-acids is nearly same as formal charge is +1 in them:

$$H_3PO_2$$
  $H_3PO_3$   $H_3PO_4$ ]

#### Strength of Bases

(a) Among alkali and alkaline earth metals the basic nature of oxides and hydroxides increases as the size of the cation increases, *i.e.*, electropositive nature increases.

LiOH < NaOH < KOH < RbOH < CsOH strength increases

 $Be(OH)_2 < Mg(OH)_2 < Ca(OH)_2 < Sr(OH)_2 < Ba(OH)_2$ strength increases

(b) Among the hydrides of the same group, the basic nature decreases.

$$\begin{array}{ccc} NH_3 &> PH_3 &> \underbrace{AsH_3 > SbH_3 > BiH_3}_{Neutral} \end{array}$$

(c) The presence of a positive charge on the atom holding the lone pair decreases the base strength while the negative charge increases the base strength.

# -•••- PRACTICE PROBLEMS -•••-

### Subjective Type Questions

- 1. In the following equations, label each species as an acid or a base. Show the conjugate acid-base pairs.
  - (a)  $HCO_3^-(aq) + HF(aq) \Longrightarrow H_2CO_3(aq) + F^-(aq)$
  - (b)  $HCO_3^-(aq) + OH^-(aq) \longrightarrow CO_3^{2-}(aq) + H_2O(l)$
- 2. In the following reactions, identify the Lewis acid and the Lewis base.
  - (a)  $Ag^+ + 2NH_3 \Longrightarrow Ag(NH_3)_2^+$
  - (b)  $B(OH)_3 + H_2O \implies B(OH)_4^- + H^+$

(c) 
$$BF_3 + CH_3OH \Longrightarrow F_3B:O-CH_3$$

- (d)  $O^{2-} + CO_2 \rightleftharpoons CO_3^{2-}$
- Identify each of the following as an acid or a base in terms of the Arrhenius concept.
  - (a) BaO (b) H<sub>2</sub>S (c) CH<sub>2</sub>NH<sub>2</sub> (d) SO<sub>2</sub>
- 4. Give the conjugate acids of :
  - (i)  $HCO_3^-$  (ii)  $HSO_4^-$
- (iii) [Fe(H<sub>2</sub>O)<sub>5</sub>(OH)]<sup>2+</sup>

- (iv) OH
- (v) SO<sub>3</sub><sup>2-</sup>
- (vi) N<sub>2</sub>H<sub>4</sub>

- (vii) Br
- (viii) CH<sub>3</sub>NH<sub>2</sub>
- (ix) PH<sub>3</sub>

[Hint: In each case the conjugate acid is formed by addition of a proton.]

- 5. Give the conjugate base of:
  - (i) OH
- (ii) NH<sub>3</sub>
- (iii) H<sub>2</sub>O

- (iv) H<sub>3</sub>O<sup>+</sup>
- (v) HCO<sub>3</sub> (viii) HS
- (vi) CH<sub>3</sub>COOH (ix) HNO<sub>3</sub>

(vii) C<sub>2</sub>H<sub>5</sub>OH (viii) HS (ix) HNO<sub>3</sub>
 [Hint: In each case, the conjugate base is formed by loss of a proton.]

6. Label the conjugate acids and bases in these reactions :

(i) 
$$S^{2-} + H_3O^+ \rightleftharpoons HS^- + H_2O$$

(ii) 
$$N_2H_4 + H_2O \rightleftharpoons N_2H_5^+ + OH^-$$

(iii) 
$$NH_2 + H_2O \rightleftharpoons NH_3 + OH^-$$

(iv) 
$$CH_3COOH + H_2O \rightleftharpoons CH_3COO^- + H_3O^+$$

(v) 
$$[AI(H_2O)_6]^{3+} + H_2O \rightleftharpoons [AI(H_2O)_5OH]^{2+} + H_3O^+$$

(vi) 
$$CO_3^2 + H_2O \rightleftharpoons HCO_3 + OH^2$$

- (vii)  $PO_4^{3-} + H_2O \Longrightarrow HPO_4^{2-} + OH^{-}$
- (viii)  $H_2Fe(CO)_4 + CH_3OH \implies [HFe(CO)_4]^- + CH_3OH_2^-$
- (ix)  $HSO_4^- + OH^- \iff SO_4^{2-} + H_2O$
- 7. Write down the conjugate acid and base of :
  - (i) NH<sub>3</sub> (ii)
- (ii) HCO<sub>3</sub>
- (iii) HSO<sub>4</sub>
- (iv) H<sub>2</sub>O (v) CH<sub>3</sub>COOH
- (vi) H<sub>2</sub>NCH<sub>2</sub>COOH
- (vii) HS (viii) OH
- 8. In the reactions, which reactant is the Lewis acid and which is the Lewis base?
  - (i)  $NH_3 + BF_3 \longrightarrow H_3N : BF_3$
  - (ii)  $\operatorname{BeF}_{2} + 2F^{-} \longrightarrow \operatorname{BeF}_{4}^{2-}$
  - (iii)  $S + SO_3^{2-} \longrightarrow S_2O_3^{2-}$
  - (iv)  $(CH_3)_3N + SO_3 \longrightarrow (CH_3)_3N : SO_3$
  - (v)  $Fe^{2+} + 6CN^{-} \longrightarrow [Fe(CN)_{6}]^{4-}$
  - (vi)  $CO_2 + OH^- \longrightarrow HCO_3$
- 9. Would each of the following species in solution tend to produce a basic, a neutral or an acidic solution?
  - (a)  $C_2H_3O^-$
- (b) Na<sup>+</sup>
- (c) SO<sub>3</sub><sup>2</sup>
- (d) F

- (e) NH<sub>4</sub>
- (f) AlCl<sub>3</sub>

[Hint: A conjugate of a weak acid produces an alkaline solution whereas a conjugate of a weak base produces an acidic solution. The aqueous solution of a species whose conjugate is strong, is neutral.]

10. Which of the following pairs is the strongest acid? Give reason for your choice:

- (a) [Fe(H<sub>2</sub>O)<sub>6</sub>]<sup>3+</sup>
- or  $[Fe(H_2O)_6]^{2+}$
- (b)  $[Al(H_2O)_6]^{3+}$
- or
- [Ga(H<sub>2</sub>O)<sub>6</sub>]<sup>3+</sup> Ge(OH)<sub>4</sub>

HClO<sub>4</sub>

H<sub>2</sub>SO<sub>4</sub>

- (c) Si (OH)<sub>4</sub> (d) HClO<sub>3</sub>
- or
  - or
- (e) H<sub>2</sub>CrO<sub>4</sub>
- or HMnO<sub>4</sub>
- (f) H<sub>3</sub>PO<sub>4</sub>

litmus to red?

- .
- 11. Answer the following :(i) What is the nature of the solution which turns blue

- (ii) What is the nature of the solution which turns red litmus to blue?
- (iii) Conjugate acid-base pair differ by ......
- (iv) Arrhenius theory of acids-bases is not applicable to
- (v) AlCl<sub>3</sub> is a Lewis acid because it is .........
- (vi) NH3 is a Lewis base because it is ..........
- (vii) The ligands in the complex compound are ......
- (viii) A substance gives H<sub>3</sub>O<sup>+</sup> ions in aqueous solution. What is that substance?
- (ix) The conjugate base of a strong acid is ......
- (x) In a reaction H+ ions combine with OH- ions to form water. What is the type of reaction?
- Arrange the following in the order of their:
  - (a) increasing acid strength HF, HCl, HBr and HI
  - (b) increasing acid strength HClO<sub>4</sub>, HClO<sub>3</sub>, HClO<sub>2</sub>, HClO
  - (c) increasing basic nature H<sub>2</sub>O, OH<sup>-</sup>, CH<sub>3</sub>OH, CH<sub>3</sub>O<sup>-</sup> [L.I.T. 1992]
  - (d) increasing acid character CO<sub>2</sub>, N<sub>2</sub>O<sub>5</sub>, SiO<sub>2</sub>, SO<sub>3</sub> [I.I.T. 1988]
  - (e) increasing basic strength ClO, ClO<sub>2</sub>, ClO<sub>3</sub>, ClO<sub>4</sub>
  - (f) increasing acid strength  $[Na(H_2O)_n]^+$ ,  $[Ca(H_2O)_n]^{2+}$ ,  $[Al(H_2O)_6]^{3+}$ ,  $[Fe(H_2O)_6]^{3+}$
  - (g) increasing basic strength F, OH, CH, NH2
  - (h) increasing acid strength CH<sub>4</sub>, NH<sub>3</sub>, H<sub>2</sub>O and HF
  - (i) increasing basic strength H<sub>3</sub>O<sup>+</sup>, H<sub>2</sub>O, OH<sup>-</sup>
  - (j) increasing basic strength CH<sub>3</sub>OH, CH<sub>3</sub>NH<sub>2</sub>, CH<sub>3</sub>F
- Predict the direction of the following reactions in aqueous solution:
  - $HNO_2 + CN^- \Longrightarrow HCN + NO_2$
  - $F^- + H_2O \Longrightarrow HF + OH^-$ (b)
  - $Na^+ + H_2O \Longrightarrow NaOH + H^+$ (c)
- Define and give one example each of the following terms:
  - (a) Bronsted-Lowry acid
- (b) Bronsted-Lowry base
- (c) Lewis acid
- (d) Lewis base
- (e) Amphoteric compound
- (f) Neutralisation
- (g) Hard acid
- (h) Soft base

#### 15. Explain giving reasons:

- (i) CCl4 does not act as a Lewis acid while SiCl4 and SnCl<sub>4</sub> do so.
  - [Hint: Carbon does not have d-orbitals to accommodate the accepted electron pair while Si and Sn possess d-orbitals and thus, accept electron pair electrons.

$$\operatorname{SnCl}_4 + 2 : \text{Ci} : \longrightarrow [\operatorname{SnCl}_6]^{2-}]$$
Lewis acid

(ii) BF<sub>3</sub> acts as a Lewis acid whereas NF<sub>3</sub> does not.

[Hint: BF3 is an electron deficient compound. It can accept an electron pair. N in NF3 has completed octet and d-orbitals are not present. It cannot accept an electron pair.]

(iii) HClO<sub>4</sub> is stronger acid than H<sub>2</sub>SO<sub>4</sub>.

[Hint: The number of terminal oxygen atoms in HClO<sub>4</sub> are three while in H2SO4 are two. Chlorine is more electronegative than S.]

(iv) Water behaves as an acid and also like a base on the basis of protonic concept.

[Hint: With strong acid, water behaves as a base as it accepts proton.

$$HCl + H_2O \iff H_3O^+ + Cl^-$$

With strong base, water behaves as an acid as it donates proton.

$$NH_2^- + H_2O \implies NH_3 + OH^-$$
]

(v) Neither pure H<sub>2</sub>SO<sub>4</sub> nor pure HClO<sub>4</sub> conducts electric current but a mixture of the two does.

[Hint: Both the pure acids are unionised. However, when mixed the stronger acid, HClO<sub>4</sub>, donates a proton to H<sub>2</sub>SO<sub>4</sub> and ions are formed.

$$HClO_4 + H_2SO_4 \rightleftharpoons H_3SO_4 + ClO_4$$

(vi) AgI<sub>2</sub> complex is more stable than AgF<sub>2</sub>.

[Hint: Ag+ ion is a soft acid. Its interaction with I ion, a soft base, yields a stable complex whereas its interaction with F ion, hard base yields an unstable complex.)

(vii) CsF reacts with LiI even though both are ionic.

[Hint: The reaction is an interesting example of preferential combination of soft-soft and hard-hard

(viii) SO<sub>3</sub> has acidic behaviour.

[Hint: Sulphur atom is attached with three very highly electronegative oxygen atoms. As a result, electrons are drawn towards oxygen atoms and S-atom remains with low electron density and thus, has the tendency to accept electrons. So, it acts as a Lewis acid.]

(ix) H<sub>3</sub>PO<sub>4</sub> is tribasic but H<sub>3</sub>PO<sub>3</sub> is dibasic in aqueous solution.

lHint: In H<sub>3</sub>PO<sub>4</sub>, three hydrogen atoms are bonded to phosphorus atom through oxygen atoms and these three hydrogen atoms are dissociated into H+ ion. Hence, H<sub>3</sub>PO<sub>4</sub> is tribasic. In H<sub>3</sub>PO<sub>3</sub>, two hydrogen atoms are bonded to phosphorus atom through oxygen atoms. So, H<sub>3</sub>PO<sub>3</sub> is dibasic.]

(x) Dilute sulphuric acid is said to be stronger than concentrated sulphuric acid.

Hint: Strength of the acid depends on the number of H<sup>+</sup> ions present in the solution. Degree of dissociation, i.e., the tendency to liberate H+ ions increases with dilution. Thus, dil. H2SO4 is stronger than conc. H<sub>2</sub>SO<sub>4</sub>.]

### Matching Type Questions

#### Match the following:

- (a)  $BF_3$
- (i) Cationic Bronsted base
- (b) NH<sub>4</sub>
- (ii) Cl
- (c) H<sub>2</sub>O
- (iii) H<sub>3</sub>PO<sub>2</sub>
- (d) [Al(H<sub>2</sub>O)<sub>5</sub>OH]<sup>2+</sup>
- (iv) Ag<sup>+</sup>
- (e) Monobasic acid Soft acid
- (v) Bronsted acid (vi)  $H^+ + OH^- \rightleftharpoons H_2O$
- (g) Hard base
- (vii) Lewis acid
- (h) Neutralisation
- (viii) Amphiprotic

	(v) Fe <sup>2+</sup>	CNT	Lone pair donated by CN and accepted by Fe <sup>2+</sup> .
	(vi) CO <sub>2</sub>	OH_	Lone pair donated by OH and accepted by CO <sub>2</sub> .

- 9.  $C_2H_3O^-$ ,  $SO_3^{2-}$  and  $F^-$  These are conjugate of weak acids, (a) (c) (d) hence their aqueous solutions are alkaline.
  - (b) Na<sup>+</sup> - It is a conjugate of a strong alkali, hence the aqueous solution is neutral.
  - (e) NH<sub>4</sub> - It is a conjugate of a weak base, hence its aqueous solution is acidic.
  - (f) AlCl<sub>3</sub> - [Al(H<sub>2</sub>O)<sub>6</sub>]<sup>3+</sup> is a conjugate of a weak base, hence its aqueous solution is acidic.

$$[AI(H_2O)_6]^{3+} + H_2O \iff [AI(H_2O)_5(OH)]^{2+} + H_3O^+$$

- 10. (a)  $[Fe(H_2O)_6]^{3+}$  Small radii and higher charge increases acid strength.
  - (b) [Al(H<sub>2</sub>O)<sub>6</sub>]<sup>3+</sup> Smaller size of Al<sup>3+</sup> than Ga<sup>3+</sup>.
  - (c) Si(OH)<sub>4</sub> Smaller size of Si than Ge.
  - (d) HClO<sub>4</sub> More electronegative oxygen atoms with Cl than in HClO3 or formal charge is more on Cl in HClO4 than in HClO<sub>3</sub>.
  - (e) HMnO<sub>4</sub> Higher oxidation number of Mn.
  - (f) H<sub>2</sub>SO<sub>4</sub> Higher electronegativity of S.
- 11. (i) Acidic, (ii) Alkaline, (iii) one proton, (iv) non-aqueous solutions, (v) an electron pair acceptor, (vi) an electron pair donor, (vii) Lewis bases, (viii) A Bronsted acid, (ix) Weak base, (x) Neutralisation.
- 12. (a) HF < HCl < HBr < HI
  - (b) HClO < HClO<sub>2</sub> < HClO<sub>3</sub> < HClO<sub>4</sub>
  - (c)  $H_2O < CH_3OH < OH^- < CH_3O^-$
  - (d)  $SiO_2 < CO_2 < N_2O_5 < SO_3$
  - (e)  $ClO_4^- < ClO_3^- < ClO_2^- < ClO_3^-$
  - (f)  $[Na(H_2O)_n]^+ < [Ca(H_2O)_n]^{2+} < [Al(H_2O)_6]^{3+} < [Fe(H_2O)_6]^{3+}$
  - (g)  $F^- < OH^- < NH_2^- < CH_3^-$
  - (h)  $CH_4 < NH_3 < H_2O < HF$
  - (i)  $H_3O^+ < H_2O < OH^-$
  - (j)  $CH_3F < CH_3OH < CH_3NH_2$
- 13. (a) The reaction moves from left to right as HNO2 is stronger than HCN, i.e., it is a better proton donor.
  - (b) HF is a strong acid than H2O. The reaction moves from right to left.
  - (c) The reaction moves from right to left as Na<sup>+</sup> is a very weak acid while NaOH is a strong alkali.

#### **Answers**: Matching Type Questions

(a-vii); (b-v); (c-viii); (d-i); (e-iii); (f-iv); (g-ii); (h-vi).

# ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. Boric acid is a weak Lewis acid. When it is dissolved in water, the aqueous solution contains ions:
  - (a)  $H_3BO_3 \rightleftharpoons H_2BO_3 + H^+$
  - (b)  $H_3BO_3 + H_2O \Longrightarrow B(OH)_4^- + H^+$
  - (c)  $H_3BO_3 \rightleftharpoons HBO_3^{2-} + 2H^+$
  - (d)  $H_3BO_3 \implies BO_3^{3-} + 3H^+$

Ans. (b)

[Hint: B(OH)<sub>3</sub>, i.e., H<sub>3</sub>BO<sub>3</sub> in aqueous medium coordinates with a molecule of water to form a hydrated species, H O→ B(OH)<sub>3</sub>. B<sup>3+</sup> ion pulls the σ-electron charge of the coordinated O-atom towards itself. The coordinated oxygen, in turn, pulls the σ-electron charge of the O→H bond of the attached water molecule towards itself. This facilitates the removal of proton ion from the O→H bond.]

- 2. Which is the correct trend of the acid strength?
  - (a)  $HClO_4 > HClO_3 > HClO_2$
  - (b)  $H_3PO_4 > H_3PO_3 > H_3PO_2$
  - (c) HF > HCl > HBr
  - (d) HC1 > HF > H<sub>2</sub>S

**Ans.** (a, d)

[Hint: (a) The number of electronegative atoms with central atom increases.

- (b) All the three have nearly same acid strength.
- (c) Acid strength increases in the hydrides in a group, if size of the central atom increases.
- (d) HCl is stronger than HF and HF is stronger than H2S.]
- 3. In  $I_3$ , Lewis base is:
  - (a) I<sub>2</sub>

(b) I<sub>2</sub><sup>+</sup>

(c)  $I_{2}^{-}$ 

(d) I

- Ans. (d)
- [Hint:  $I_2 + \Gamma \longrightarrow I_3^-$ ]

Acid Base

- 4. AlCl<sub>3</sub> acts as an acid according to the concept of:
  - (a) Bronsted-Lowry
- (b) Arrhenius
- (c) Lewis
- (d) all of these

Ans. (c)

[Hint: Al in AlCl<sub>3</sub> is electron deficient. It can accept an electron pair.]

- 5. The conjugate base of NH<sub>3</sub> is:
  - (a) NH<sub>4</sub>
- (b)  $NH_2^-$
- (c) NH<sup>2-</sup>

(d) NH2OH

Ans. (b)

[Hint:  $NH_3 \rightleftharpoons NH_2^- + H^+$ ]

Acid Base

- 6. 1 mole of H<sub>3</sub>PO<sub>3</sub> is neutralised by.....mole/s of NaOH:
  - (a) 6 Ans. (c)
- (b) 3
- (c) 2
- (d) 1

**[Hint**:  $H_3PO_3$  is a dibasic acid.  $H_3PO_3 \rightleftharpoons 2H^+ + HPO_3^{2-}$ ]

7. Consider the following Lewis acid-base reaction,

$$SnCl_4 + 2Cl^- \longrightarrow SnCl_6^2$$
Acid

Hybridization of Sn in SnCl<sub>4</sub> and SnCl<sub>6</sub><sup>2-</sup> are respectively:

- (a)  $sp^3$ ,  $sp^3d^2$
- (b)  $dsp^2$  to  $sp^3d^2$
- (c)  $sp^3$ ,  $sp^3d^3$
- (d)  $sp^3$  to  $d^2sp^3$

Ans. (a)

- 8. Which of the following statements is incorrect?
  - (a) Liquid ammonia like water is an amphiprotic.
  - (b) In the equation,  $Ag^+ + 2CN^- \longrightarrow [Ag(CN)_2]^-$ ,  $Ag^+$  ion acts as a Lewis acid.
  - (c) I<sup>−</sup> ion is a Lewis as well as Bronsted base.
  - (d) BF3 is a Lewis as well as Bronsted acid.

Ans. (d

[Hint : (a)  $NH_3 + NH_3 \rightleftharpoons NH_4^+ + NH_2^-$ Acid Base Acid Base

- (b) Ag<sup>+</sup> acts as a Lewis acid as it accepts lone pairs of electrons from CN<sup>-</sup> ions.
- (c) I<sup>-</sup> ion contains lone pair of electrons which it can donate, hence it can act as a Lewis base. I<sup>-</sup> can accept proton, hence it acts as a Bronsted base.
- (d) BF<sub>3</sub> acts as a Lewis acid as it is an electron pair acceptor but it has no tendency to lose a proton, hence it is not a Bronsted acid.]
- 9. Given,

Acid

- $pK_a$ (i)
- (A) CH<sub>3</sub>CO<sub>2</sub>H (B) CCl<sub>3</sub>CO<sub>2</sub>H
- (i) 0.7 (ii) 0.2
- (C) CICH<sub>2</sub>CO<sub>2</sub>H
- (iii) 4.8
- (D) F<sub>3</sub>CCO<sub>2</sub>H
- (iv) 2.9

The correct code is:

A B C D

- (a) (iii) (i) (iv) (ii) (b) (ii) (iv) (i) (iii)
- (c) (iii) (ii) (i) (iv)
- (d) (i) (iii) (ii) (iv)
- Ans. (a)

**[Hint:** Smaller the value of the  $pK_a$  indicates the stronger acid.]

- 10. Which of the following represent conjugate acid-base pairs?
  - (a) H<sub>2</sub>O, H<sub>3</sub>O<sup>+</sup>
- (b) OH<sup>-</sup>, HNO<sub>3</sub>
- (c) H<sub>2</sub>SO<sub>4</sub>, SO<sub>4</sub><sup>2-</sup>
- (d) HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>, C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>

Ans. (a, d)

lHint: The conjugate acid-base pairs differ by H+.

$$\begin{pmatrix} H_2O & H_3O^+ \\ Base & Acid \end{pmatrix}; \; \begin{pmatrix} HC_2H_3O_2 & C_2H_3O_2^- \\ Acid & Base \end{pmatrix} J$$

Tat.	e: Choose the correct answer out of given altern	ativo	e in each assection	
		auve		_
	Acids are the substances that yield H <sup>+</sup> ions in aqueous			
	solutions while bases yield OH <sup>-</sup> ions. In a neutral solution:		(6) 112004	
	(a) There are no H <sup>+</sup> ions	15.	Which of the following is a soft acid according to Pearson	ı's
	(b) There are no OH <sup>-</sup> ions	٠,	concept ?	
	(c) There are neither H <sup>+</sup> nor OH <sup>-</sup> ions		(a) $Ag^+$	
	(d) H <sup>+</sup> and OH <sup>-</sup> ions are present in very small but equal in		(c) $A1^{3+}$	
	number	16.	The conjugate acid of HPO <sub>4</sub> <sup>2-</sup> is:	
	Which of the following is a weakest base?			
	(a) NaOH $\Box$ (b) $Zn(OH)_2$ $\Box$	٠,	2	
	(c) KOH $\Box$ (d) Ca(OH) <sub>2</sub> $\Box$	17		_
	Which of the following represents acid-base pair for the	. 17.	Which of the following is a Lewis base?	
	equilibrium reaction,		(-,	
	$HCl + H_2O \Longrightarrow H_3O^+ + Cl^-$ ?			
	(a) HCl, $H_2O$ $\Box$ (b) HCl, $H_3O^+$ $\Box$	18.	In the reaction,	
	(c) HCl, Cl <sup>-</sup> $\square$ (d) Cl <sup>-</sup> , H <sub>2</sub> O $\square$		$BCl_3 + PH_3 \rightarrow Cl_3B \leftarrow PH_3$ , Lewis base is :	
4.	The conjugate acid of $S_2O_8^{2-}$ is :		(a) $BCl_3$	
	(a) $HS_2O_8^-$		(c) Cl <sub>3</sub> B—PH <sub>3</sub>	
	(c) $H_2SO_4$ $\square$ (d) $H_2S_2O_3$ $\square$	19.	In the reaction,	
5.	The conjugate base of $H_2PO_4^-$ is : [C.E.T. (Karnataka) 2008]		$HC_2O_4^- + PO_4^{3-} \iff HPO_4^{2-} + C_2O_4^{2-}$	
	(a) $H_3PO_4$		which are the two Bronsted bases ?	
	(c) $PO_4^{3-}$ $\square$ (d) $H_3PO_3$ $\square$			_
6. ·	Which of the following is a Lewis acid?		2 0	
	(a) $NH_3$ $\square$ (b) $H_2SO_4$ $\square$			
	(c) $H_3\overset{+}{O}$ $\Box$ (d) $AlCl_3$	20.	The conjugate acid of NH <sub>2</sub> is:	
7	BF <sub>3</sub> is taken as an example of Lewis acid because it behaves:		(a) $NH_3$ $\Box$ (b) $NH_2OH$	
′.	(a) electrophile $\Box$ (b) nucleophile $\Box$		(c) $NH_4^+$ $\square$ (d) $N_2H_4$	
	(c) neutral molecule	21.	The strongest Bronsted base in the following anion is:	
8	The strongest acid of the following is:		(a) $ClO^-$	
0.	(a) HCl			
	(c) $HClO_4$ $\Box$ (d) $H_3PO_4$ $\Box$	22.	The strongest Lewis base among the following is:	
Q	Which of the following is the Bronsted acid?		(a) OH	
٠.	(a) Cl		· -	
	(c) HCOO	200	•	ш
10	The reaction of water with ammonia is given by the	23.	Which of the following is a Lewis acid?	_
10.	following equation,		(a) $PCl_5$ $\square$ (b) $NCl_3$	Ш
	H <sub>2</sub> O + NH <sub>3</sub> $\rightleftharpoons$ NH <sub>4</sub> <sup>+</sup> + OH <sup>-</sup>			
	in this reaction water behaves as:	24.	The following equilibrium is established when HCl	is
	(a) neutral		dissolved the acetic acid,	
	the state of the s		$HCI + CH_3COOH \rightleftharpoons CI^- + CH_3COOH_2^+$	
11.			the set that characterises the conjugate acid-base pairs is	3:
11.	The compound that is not a Lewis acid is:		(a) (HCl, CH <sub>3</sub> COOH) and (Cl <sup>-</sup> , CH <sub>3</sub> COOH <sub>2</sub> <sup>+</sup> )	
·	(a) $BF_3$ $\square$ (b) $BaCl_2$ $\square$ (c) $AlCl_2$ $\square$ (d) $SnCl_4$ $\square$		(b) (HCl, CH <sub>3</sub> COOH <sub>2</sub> ) and (CH <sub>3</sub> COOH, Cl <sup>-</sup> )	
10	— · · · · · · · · · · · · · · · · · · ·		(c) $(CH_3COOH_2^+, HCI)$ and $(CI^-, CH_3COOH)$	
12.	Weakest acid of the following is:	,	(d) (HCl, Cl <sup>-</sup> ) and (CH <sub>3</sub> COOH <sub>2</sub> , CH <sub>3</sub> COOH)	
	(a) ClO <sub>3</sub> (OH)	25		ш
12	(c) SO(OH) <sub>2</sub>	25.		
13.	Ionic theory of acids and bases was proposed by:		OH <sup>-</sup> , NH <sub>2</sub> , H—C $\equiv$ C <sup>-</sup> and CH <sub>3</sub> —CH <sub>2</sub> ?	
	(a) Lowry		(a) $CH_3 - CH_2^- > NH_2^- > H - C = C^- > OH^-$	
14	(c) Lewis		(b) $H-C \equiv C^- > CH_3-CH_2^- > NH_2^- > OH^-$	
14.	Which of the following can act as both a Bronsted acid and		(c) $OH^- > NH_2^- > HC \equiv C^- > CH_3CH_2^-$	
	a Bronsted base ?		(d) $NH_2^- > H - C = C^- > OH^- > CH_3 - CH_2^-$	

26.	Which is the weakest base among the following?	39.	For HCl + CH <sub>3</sub> COOH system, acetic acid serve	
	(a) $C1^-$		(a) protophilic solvent   (b) protogenic so	olvent 🗆
	(c) $Br^ \square$ (d) $F^-$	,	(c) aprotic solvent $\Box$ (d) none of these	. 🗖
27.	Among the trihalides of nitrogen, which one is the least	40.	Ampholyte is:	•
	basic?		(a) $H_2O$	
	(a) $NI_3$ $\Box$ (b) $NBr_3$ $\Box$		(c) $H_2NCH_2COOH$ $\Box$ (d) all of these	
	(c) $NCl_3$ $\square$ (d) $NF_3$ $\square$	41.	A reaction between AlCl <sub>3</sub> and NH <sub>3</sub> is called:	
28.	In which of the following cases the acid strength is highest?		(a) addition   (b) substitution	· 🗆
	(a) $pK_a = 5$		(c) neutralisation	. 🗆
	(c) $K_a = 10^{-6}$	42.	Which of the following gases on dissolution in	water make
29.	Dissociation of H <sub>3</sub> PO <sub>3</sub> occurs in stages.		the solution acidic ?	
	(a) 1		(A) CO, (B) CO <sub>2</sub> , (C) SO <sub>3</sub> and (D) PH <sub>3</sub>	
	(c) 3	-	(a) (A) and (B) $\square$ (b) (B) and (C)	
30.	The strength of the acid depends on the :		(c) (C) and (D) $\square$ (d) (B) and (D)	
00.	(a) number of hydrogen atoms present in the molecule □	13	Acid strength of the weak acids $HA_1$ , $HA_2$ and	
		40.		This can be
		1	written as,	
	(c) oxygen content		$HA_1 < HA_2$ and $HA_3 < HA_1$	
	(d) concentration of hydrogen ions furnished by ionisation		the correct order of strength of the conjugate b	ases would
			be:	
31.	The dissociation constants of acids $HA$ , $HB_r$ $HC$ and $HD$		(a) $A_3^- > A_1^- > A_2^-$	
	are $3 \times 10^{-5}$ , $5 \times 10^{-9}$ , $1 \times 10^{-2}$ and $7 \times 10^{-5}$ respectively. The		(c) $A_1^- = A_3^- < A_2^-$ (d) none of these	
	weakest acid is:	44.	* *	orkee 1991]
	(a) $HD$ $\square$ (b) $HA$ $\square$		(a) $H_2CO_3$ and $HCO_3$ $\square$ (b) $H_2CO_3$ and $H_2CO_3$ $\square$	
	(c) $HB$ $\square$ (d) $HC$ $\square$		(c) $CO_3^{2-}$ and $H_3O^+$	<sub>2</sub> O
32.	On the basis of acid-base concept, the redox reactions	45.	For the reaction,	
	are also considered as acid-base reaction.		$NH_4^+ + S^{2-} \longrightarrow NH_3 + HS^-,$	
	(a) Arrhenius $\Box$ (b) Lewis $\Box$		$NH_3$ and $S^{2-}$ are a group of :	
	(c) Usanovich $\Box$ (d) Bronsted-Lowry $\Box$		(a) bases	
33.	The concept that acid is proton donor and base is proton		(b) acids	
	acceptor was given by :		(c) conjugate pair of acid and base	
*	(a) Arrhenius $\Box$ (b) Bronsted-Lowry $\Box$		(d) none of the above	
	(c) Lewis	46.	HNO <sub>3</sub> and HF both are acids. But when HNO <sub>3</sub>	dissolves in
34.	According to Lewis concept, the acid is:		HF, it behaves as :	
	(a) proton acceptor $\Box$ (b) electron-pair donor $\Box$		(a) an acid	
	(c) electron pair acceptor □ (d) proton donor □		(c) a Zwitter ion   (d) amphiprotic	solvent $\square$
35.	According to the Lewis acid-base concept:	47.	Which of the following is not a Lewis acid?	
	(a) molecule in which all atoms have their octets is an acid		•	(M.P.) 2002]
			(a) CO	
	(b) negatively charged ions are acids		(c) $SO_3$	
	(c) all positively charged ions are not acids	48.		
	(d) molecule in which a central atom has available <i>d</i> -orbital	10.	•	.E.E.E. 2002]
	to accommodate electron pair is an acid		(a) $HSO_4^-$	
36.	Which of the following is a Lewis base?	ļ	(c) $NH_3$ $\square$ (d) $OH^-$	
	(a) $CH_3NH_2$	10	In the equation : $I_2 + I^- \longrightarrow I_3$ , which is the I	
	2	49.		(Raj.) 2002]
. 27		. }		
37.	According to Lowry-Bronsted concept, the relative strength		(a) I <sub>2</sub>	
	of the bases CH <sub>3</sub> COO <sup>-</sup> , OH <sup>-</sup> and Cl <sup>-</sup> follows the order:		(c) $I_3$	e 🗆
	(a) CH <sub>3</sub> COO <sup>-</sup> > OH <sup>-</sup> > CI <sup>-</sup>	50.		
	(b) OH <sup>-</sup> > CH <sub>3</sub> COO <sup>-</sup> > Cl <sup>-</sup>		(a) H <sub>3</sub> O, HPO <sub>2</sub> <sup>2</sup> , HCO <sub>3</sub>	
	(c) CH <sub>3</sub> COO <sup>-</sup> > CI <sup>-</sup> > OH <sup>-</sup>		(b) H <sub>2</sub> O, HPO <sub>3</sub> <sup>2</sup> , H <sub>2</sub> PO <sub>2</sub> <sup>2</sup>	
	(d) $OH^- > CI^- > CH_3COO^-$		(c) $HSO_4$ , $H_2PO_4$ , $H_2PO_3$	. 🖳
38.	ĕ		(d) All of these	
	Bronsted acid?	51.	Which does not react with NaOH?	
	(a) HCl $\Box$ (b) H <sub>2</sub> SO <sub>4</sub> $\Box$		(a) $NaH_2PO_2$	
	(c) $HSO_3^ \Box$ (d) $SO_3$ $\Box$		(c) $Na_2HPO_2$ $\Box$ (d) $NaHCO_3$	. 0

52.	$[Cu(H_2O)_3(OH)]^+ + [Al(H_2O)_6]^{3+} \longrightarrow [Cu(H_2O)_4]^{2+}$		(a) (iii) $<$ (i) $<$ (iv) $<$ (ii) $\square$ (b) (iv) $<$ (ii) $<$ (iii) $<$ (i)	
	$A_1$ $A_2$ $A_3$		(c) (ii) $<$ (iii) $<$ (i) $<$ (iv) $\Box$ (d) (i) $<$ (iii) $<$ (ii) $<$ (iv)	
	+ $[Al(H_2O)_5(OH)]^{2+}$	64.	$H_3PO_3$ has non-ionisable P—H bond or bonds.	
	$A_4$		[J.E.E. (Orissa) 2	2008]
	(a) $A_1$ is an acid and $A_2$ is a base		(a) none	
	(b) $A_1$ is a base and $A_2$ is an acid		(c) 2	
	(c) $A_3$ is conjugate acid of $A_1$ and $A_4$ is conjugate base of	65.	Which is tribasic acid? [B.C.E.C.E. 2	2008]
	$A_2$		(a) $H_3PO_2$	
	(d) $A_3$ is conjugate base of $A_1$ and $A_4$ is conjugate acid of		(c) $H_4P_2O_7$	
	$A_2$	66.	Identify Bronsted-Lowry acids in the reaction given :	
53.	Water is a : [K.C.E.T. 2002]		$[Al(H_2O)_6]^{3+} + HCO_3^- \longrightarrow [Al(H_2O)_5(OH^-)]^{2+} + H_2CO$	)_
00.	(a) protophobic solvent $\square$ (b) protophilic solvent $\square$		$\begin{array}{cccc} (A) & (B) & (C) & (D) \end{array}$	3
	(c) amphiprotic solvent (d) aprotic solvent (		The correct answer is: [E.A.M.C.E.T. (Med.) 2	2008]
54.	Ammonium ion is: [K.C.E.T. 2002]		(a) (A), (C)	
V 2.	(a) a conjugate acid		(c) $(A)$ , $(D)$ $\Box$ (d) $(B)$ , $(C)$	
	(b) a conjugate base	67.	Which is correct trend of the acid strength?	
	(c) neither an acid nor a base		(a) $H_2S > H_2O > HF$	
	(d) both an acid and a base		(b) HClO <sub>4</sub> > HClO <sub>3</sub> > HClO <sub>2</sub>	
55	H <sub>3</sub> PO <sub>3</sub> phosphorus acid is : [P.M.T. (Kerala) 2003]		(c) $H_3PO_4 > H_3PO_3 > H_3PO_2$	
50.	(a) diprotic acid		(d) $HNO_2 > HNO_3 > H_2N_2O_2$	
	(c) monoprotic acid	68.	The order of Lewis acid strength is:	
56	Arrange NH $_{+}^{4}$ , H $_{2}^{2}$ O, H $_{3}^{+}$ O, HF and OH $_{-}^{-}$ in increasing order		(a) $BBr_3 > BCl_3 > BF_3$ $\square$ (b) $BCl_3 > BBr_3 > BF_3$	
00.	of acidic nature : [B.V. (Pune) 2003]		(c) $BF_3 > BCl_3 > BBr_3$ $\square$ (d) $BCl_3 > BrF_3 > BBr_3$	
	(a) $H_3O^+ < NH_4^+ < HF < OH^- < H_2O$	69.	The increasing order of acidity of H <sub>2</sub> O <sub>2</sub> , H <sub>2</sub> O and CO	b is:
	(b) $NH_4^+ < HF < H_3O^+ < H_2O < OH^-$		(a) $H_2O_2 > H_2O > CO_2$ (b) $H_2O_2 > CO_2 > H_2O$	
	(c) $OH^- < H_2O < NH_4^+ < HF < H_3O^+$		(c) $H_2O > H_2O_2 > CO_2$	
	(d) $H_3O^+ > HF > H_2O > NH_4^+ > OH^-$	`70.	The true statement for the acids of phosphorus, H <sub>3</sub>	2PO2,
57	Which among the following is amphoteric oxide?		H <sub>3</sub> PO <sub>3</sub> and H <sub>3</sub> PO <sub>4</sub> is:	
<b>.</b> .		i	(a) all of them are reducing agents	
	1A.I.E.E.E. 20031	l	(a) an or them are reducing agents	_
	[A.I.E.E.E. 2003] (a) ZnO		(b) all of them are tribasic acids

Objective Questions for IIT ASPIRANTS

### Matrix Matching Questions for IIT Aspirants

1. Match List-II with List-II:

#### List-I

#### List-II

(a) HF

(p) Strongest acid

(b) HCl

(q) React with glass

(c) HBr

(r) Monobasic

(d) HI

- (s) Strongest reducing agent
- 2. Match the solvents in List-I with their classifications in List-II:

#### List-I

#### List-II

- (a) Benzene
- (p) Protogenic
- (b) Water
- (q) Protophilic
- (c) Liquid NH<sub>3</sub>
- (r) Amphiprotic
- (d)  $CS_2(l)$
- (s) Aprotonic
- 3. Match List-I with List-II:

#### List-I

#### List-II

(a) OH-

- (p) Conjugate acid of O<sup>2-</sup>
- (b) HClO<sub>4</sub>
- (q) Conjugate acid of H2O
- (c)  $H_3O^+$
- (r) Conjugate base of H2O

- (d) ClO<sub>4</sub> is weakest conjugate base of
- (s) Strongest Bronsted acid
- (e) CH<sub>4</sub>
- (t) Weakest Bronsted acid
- · Match List-I with List-II:

#### List-I

#### List-II

- (a) Molecules with empty
- (p) Lewis base
- d-orbital with the central atom
- (b) Molecules with incomplete (q) Electron pair acceptor
- octet (c) Multiple bonded
- (r) Lewis acid
- compounds like CO, NO (d) R— $NH_2$ , R—O—H
- (s) Electron pair donor
- 5. Match List-I with List-II:

#### List-I

#### List-II

- (a) Oxide ion donor
- (p) Acid-base equilibrium
- (b) CaO  $\rightleftharpoons$  Ca<sup>2+</sup> + O<sup>2-</sup> (c) SO<sub>3</sub>
- (r) Hard base

(d)  $CO_3^{2-}$ 

(s) Base (lux-flood)

(q) Acid (lux-flood)

- (a-q)
- (b-r)
- (c-r)
- (d-p, r, s)
- (d-s)
  - (d-s)
- 4. (a-q, r) (a-s)
- (b-q, r) (b-p)
- (c-p, s) (c-q, r)
- (d-p, s) (d-r, s)

- (a-s) (b-p, q, r) (b-s)(a-p, r)
- (c-q)(c-q)

- (e-t)

# **Assertion-Reason Type Questions**

The following questions consist of an Assertion (A) and Reason (R). Use the following key to choose the correct answer:

- (a) If both (A) and (R) are correct and (R) is the correct explanation of (A).
- (b) If both (A) and (R) are correct but (R) is not the correct explanation of (A).
- (c) If (A) is correct but (R) is incorrect.
- (d) If both (A) and (R) are incorrect.
- (e) If (A) is incorrect but (R) is correct.
- 1. (A) HClO<sub>4</sub> is stronger acid than HClO<sub>3</sub>.
  - (R) Oxidation state of Cl is + 8 in HClO<sub>4</sub> and in HClO<sub>3</sub> is
- 2. (A) BF<sub>3</sub> is a Lewis acid as well as Bronsted-Lowry acid.
  - (R) Any species which can accept a lone pair of electrons is a Lewis acid and the species that can lose a proton is Bronsted-Lowry acid.

- 3. (A) If a base is strong, its conjugate acid is weak.
  - (R) HA is a conjugate acid of the base A<sup>-</sup>.
- 4. (A)  $H_2PO_3^-$  is amphiprotic.
  - (R) H<sub>2</sub>PO<sub>3</sub> can act as an acid by losing a proton as well as a base by accepting a proton.
- 5. (A) pH of 10<sup>-9</sup> N HCl is 9.
  - (R) pH is defined as the negative logarithm of [H<sup>+</sup>].
- 6. (A) CaO donates oxide, hence it is a base and CO2 accepts an oxide, hence it is an acid. This is in accordance with Lux-Flood concept.
  - (R) Cu<sup>+</sup>, Ag<sup>+</sup>, Au<sup>+</sup>, etc., are soft acids while Li<sup>+</sup>, Na<sup>+</sup>, Ca<sup>+</sup>, etc., are hard acids.
- Molecular mass 7. (A) Equivalent mass of a base =

Acidity

(R) Acidity is the number of replaceable hydrogen atoms in one molecule of the base. [A.I.E.E.E. 2008]

- 1. (c)
- 2. (e)
- 3. (b)
- 4. (a)
- 5. (e)
- 6. (b)
- 7. (c)

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

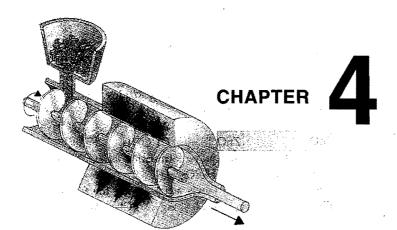

- 2. The total number of triprotic acids among the following is:  $H_3PO_4$ ,  $H_3PO_3$ ,  $H_3PO_2$ ,  $H_3BO_3$ ,  $H_4P_2O_7$
- 3. The total number of amphoteric oxides and hydroxides among the following is:

 $Na_2O$  CaO  $Al(OH)_3$   $Cr(OH)_3$  SnO ZnO  $Ca(OH)_2$   $Fe(OH)_3$ 

- **4.** Oxy acids in general can be formulated as  $XO_n(OH)_m$ . What is the value of 'm' in  $H_3PO_3$ ?
- 5. The total number of Lewis acids among the following is :  $BF_3$ ,  $H_2O$ ,  $NH_3$ ,  $AlCl_3$ ,  $Ag^+$ ,  $PCl_3$ , R— $NH_2$

### Answers

- 1. (6) Six out of the given acids are diprotic.  $H_2S_2O_7$ ,  $H_2SO_3$ ,  $H_2SO_4$ ,  $H_3PO_3$ ,  $H_2CO_3$ ,  $H_2CO_4$
- 2. (1) Only H<sub>3</sub>PO<sub>4</sub>
- 3. (4) SnO, ZnO, Al(OH)3 and Cr(OH)3 are amphoteric in nature.
- (2) H<sub>3</sub>PO<sub>3</sub> is diprotic. It has two —OH groups. It is represented as HPO(OH)<sub>2</sub>.
- 5. (4) BF<sub>3</sub>, AlCl<sub>3</sub>, Ag<sup>+</sup>, PCl<sub>3</sub> are Lewis acids.

the Earth as the metal itself. The vein
of gold are shown in this rock

### 4.1 OCCURRENCE OF ELEMENTS

All materials found in the earth are composed of chemical elements. At present 117\* elements are known but all of them do not occur in nature. Out of the 92 elements from hydrogen to uranium all with the exception of few such as technetium, promethium, astatine, francium, etc., are found in earth. The elements above uranium are man-made which have been synthesised by artificial means. These elements are called **transuranic elements** and are radioactive in nature.

Out of naturally occurring elements, only ten elements make up about 99% mass of the earth's crust, oceans and atmosphere. The first ten most abundant elements in nature (earth's crust, oceans and atmosphere) are:

1. Oxygen	2. Silicon	3. Aluminium	<b>4.</b> Iron	5. Calcium
(49.5%)	(25.7%)	(7.5%)	(4.7%)	(3.4%)
6. Sodium	7. Potassium	8. Magnesium	9. Hydrogen	10. Titanium
(2.6%)	(2.4%)	(1.9%)	(0.87%)	(0.58%)

Thus, a few elements are very abundant, but most of the elements are very scarce. [Some of the common elements such as copper, zinc, tin and lead are not abundant but are found in nature in rich deposits from which these can be easily extracted.]

If the entire universe is considered, then 90% of the matter is hydrogen. Helium is the second most abundant element amounting to 9% and the remaining elements make up only 1% of the universe with oxygen, neon, carbon and nitrogen next in order of decreasing abundance.

The natural mode of occurrence of an element is largely dependent upon its chemical nature. The elements occur in nature sometimes free (or native) but mostly in the combined state.

(i) Native state: The elements which are least reactive and have little or no affinity for oxygen, moisture and other chemical reagents occur in a free or native state, *i.e.*, in uncombined state, *e.g.*, gold (Fig. 4.1), silver and platinum metals are found in native state. Liquid droplets of mercury are

<sup>\*</sup>Recently, elements with atomic numbers 113, 115 and 118 have been reported.

found associated with cinnabar (HgS). Nitrogen, oxygen and noble gases are found in free state in the atmosphere. Carbon in the form of diamond, graphite and coal is found in a free state in earth's crust. Deposits of sulphur are also found deep underground in uncombined state.

(ii) Combined state: Elements which are chemically reactive, *i.e.*, are readily affected by oxygen, moisture, CO<sub>2</sub>, etc., of the atmosphere occur in a combined state in the form of simple or complex compounds. These compounds are called **minerals**. In the combined state, elements are generally present as oxides, carbonates, sulphides, silicates,

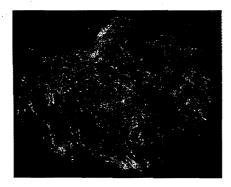

Fig. 4.2 Element in combined state : Ruby, an ore of aluminium, is aluminium oxide,  $Al_2O_3$ , containing a small percentage of chromium oxide,  $Cr_2O_3$ 

halides, sulphates, etc. A few common elements along with their nature of occurrence have been listed in the following table.

### SOME COMMON ELEMENTS WITH THEIR NATURE OF OCCURRENCE

Element	Nature of	Name of	Composition of
Element	occurrence	minerals	minerals
Aluminium	Oxide	Bauxite	Al <sub>2</sub> O <sub>3</sub> ·2H <sub>2</sub> O
		Corundum	$Al_2O_3$
		Diaspore	Al <sub>2</sub> O <sub>3</sub> ·H <sub>2</sub> O
	Fluoride	Cryolite	Na <sub>3</sub> AlF <sub>6</sub>
	Silicate	China clay	Al <sub>2</sub> O <sub>3</sub> ·2SiO <sub>2</sub> ·2H <sub>2</sub> O
		Mica	$K_2O \cdot 3Al_2O_3 \cdot 6SiO_2 \cdot 2H_2O$
*		Feldspar	KAlSi <sub>3</sub> O <sub>8</sub>

		contain louides	

Earth is the storehouse of a large number of elements. The distribution of these elements is not uniform. The elements are distributed in three main parts of the earth known as atmosphere, hydrosphere and lithosphere.

- **(A) Atmosphere :** It is a blanket of gases which is surrounding the lithosphere and hydrosphere parts of the earth. It has no well defined upper limits and gradually merges with the outer space. Of the total mass of atmosphere, about 99% is within a height of 30 km from the earth's surface. The major gases in the atmosphere are nitrogen (78%) and oxygen (21%) by volume. Remaining 1% account for other gases such as argon, neon, krypton, xenon, helium, carbon dioxide, etc.
- **(B) Hydrosphere:** The liquid phase of the earth is called the **hydrosphere**. It covers about 80% of the earth's surface and constitutes lakes, streams, rivers and oceans. There are

a large number of elements in the form of their dissolved salts present in sea water.

Although, sea water contains elements like Na, Mg, Ca, K, Sr, Ba, Cl, Br, S, Li, Al, Rb, etc., only four elements Na, Mg, Cl and Br are commercially obtained from sea water. Sulphur, tin, gold, natural gas and petroleum are also being obtained from sea sources. Iodine, agar-agar, laminarin are the products which are recovered from seaweeds. Efforts are on to extract some of the rare metals from the rock-like objects called **nodules** found on the sea floor.

**(C) Lithosphere:** It is the outermost solid part of the earth and consists of different types of rocks. Almost all the naturally occurring elements are found in the lithosphere. It consists of different types of rocks in which various elements are present in the form of minerals. The distribution of main

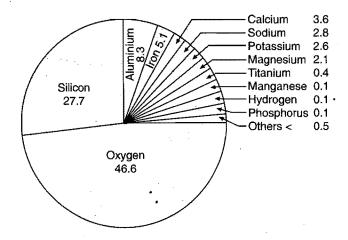

Fig. 4.3 Percentage distribution of different elements in lithosphere

elements in terms of their relative abundance in the lithosphere is shown in Fig. 4.3. It is observed that,

- (i) Oxygen and silicon constitute about 73% by mass of the earth's crust.
- (ii) First five elements comprise almost 92% by mass of the earth's crust.
- (iii) Aluminium is the most abundant normal or representative element.
- (iv) Iron is the most abundant transition metal.
- (v) First ten make up over 99.5% and first twenty make up 99.97% by mass of the earth's crust.

#### Elements in Living Organisms

Animals and plants organisms consist of complex substances composed of both metallic and non-metallic elements. When the analysis of ash of animal tissues is carried out, it is observed that about 30 elements are present in the animal tissues. Abundance of selected elements in the human body (mass %) is given ahead:

O	65.0	Mg	 0.5
C	18.0	K	0.34
H	10.0	S	0.26
N	3.0	Na	0.14
Ca	2.4	Cl	0.15
P	1.0 *	· Fe	0.005

Besides these, the following elements are present in very small amounts:

Cu, Zn, Co, Mn, Mo, I and F.

Many elements get accumulated in living organisms. Some examples are: (i) iodine in seaweeds (ii) vanadium in cucumbers (iii) potassium in plants. The reason for such accumulation is not yet known. Living organisms also contain different elements in different parts. For example:

- (i) Carbon, hydrogen, nitrogen and oxygen are the major constituents of biomolecules which are present in the bodies of animals and plants.
- (ii) Iron is present in haemoglobin—a red pigment of blood cells.
- (iii) **Magnesium** is a constituent of chlorophyll—a green pigment of plants responsible for photosynthesis.
- (iv) Zinc is present in the eyes of certain animals.
- (v) Manganese, iron and copper are present in chloroplasts.
- (vi) Calcium and phosphorus are present in the teeth and bones of animals.

It is important to note that very little is known as to why a particular element is present in a specific region of the living organism. However, it is known that deficiency of a particular element in the living organism brings many disorders. For example, deficiency of iron causes anaemia while that of iodine causes goitre. Similarly, the deficiency of nitrogen, phosphorus and potassium in plants retards their growth.

# 4.2 OCCURRENCE OF METALS (Minerals and Ores)

The earth's crust is the biggest source of metals. Metals occur in nature sometimes free but mostly in a combined state. The rocks in which metals occur in the native state or combined state (in the form of compounds) are called minerals. Every mineral has a definite composition. It may be a single compound or a complex mixture, usually associated with a number of impurities. The minerals from which the metals can be conveniently and economically extracted are known as ores.

All the ores are minerals but all minerals cannot be ores. For example, iron is found in the earth's crust as oxides, sulphides and carbonate.

Haematite	$Fe_2O_3$
Magnetite	$Fe_3O_4$
Iron pyrites	FeS <sub>2</sub>
Copper pyrites	CuFeS <sub>2</sub>
Siderite	FeCO <sub>3</sub>

Out of the above minerals iron is extracted from oxides. Thus, oxides of iron, *i.e.*, **haematite**, **magnetite**, etc., are the **ores of iron**. The minerals of copper are:

Cuprite	Cu <sub>2</sub> O
Copper glance	Cu <sub>2</sub> S
Copper pyrites	CuFeS <sub>2</sub>
Malachite	CuCO <sub>3</sub> · Cu(OH) <sub>2</sub>
Azurite	2CuCO <sub>3</sub> · Cu(OH) <sub>2</sub>

Copper is conveniently and economically extracted from copper pyrites. Thus, **copper pyrites** is the **ore of copper.** Similarly, aluminium has several minerals such as:

Bauxite	$Al_2O_3$ · $2H_2O$
Cryolite	Na <sub>3</sub> AlF <sub>6</sub>
China clay	Al <sub>2</sub> O <sub>3</sub> · 2SiO <sub>2</sub> · 2H <sub>2</sub> O
Feldspar	KAlSi <sub>3</sub> O <sub>8</sub>
Mica	K2O:3Al2O2: 6SiO2: 2H2O

However, the mineral bauxite is used for the extraction of aluminium. Thus, bauxite is an ore of aluminium.

It is evident from the above examples that a metal may occur in a number of minerals but every mineral is not suitable for the extraction of the metal. This is because the mineral may contain low concentration of metal or may contain a large concentration of impurities which may not be easy to remove or process of extraction may not be feasible or commercially viable.

Ores may be divided into four groups:

- (i) **Native ores:** These ores contain metals in a free state, e.g., silver, gold, platinum, mercury, copper, etc. These are found usually associated with rock or alluvial materials like clay, sand, etc. Sometimes lumps of pure metals are also found. These are termed **nuggets**. Iron is found in free state as meteorites which also have 20 to 30% nickel.
- (ii) Sulphurise.1 and arsenical ores: These ores consist of sulphides and arsenides in simple and complex forms of metals. Important ores of this group are:

Metal	Name of the ore	Composition
Pb	Galena	PbS
Zn	Zinc blende	ZnS
Hg	Cinnabar	HgS
Ag	Argentite or silver glance	Ag <sub>2</sub> S
Ni	Kupfer nickel	NiAs
Cu	Copper pyrite	CuFeS <sub>2</sub>

(iii) Halide ores: Metallic halides are very few in nature. Chlorides are most common. For example,

Metal	Name of the ore	Composition
Na	Common salt	NaCl
K and Mg	Carnallite	KCl· MgCl <sub>2</sub> · 6H <sub>2</sub> O
Ag	Horn silver	AgCl

(iv) Oxidised ores: In these ores, metals are present as their oxides or oxysalts such as carbonates, sulphates, phosphates, silicates, etc.

Important ores of this group are:

Metal	Name of the o	ore Composition
Al	Bauxite	Al <sub>2</sub> O <sub>3</sub> · 2H <sub>2</sub> O
·Sn	Tin stone	SnO <sub>2</sub>
	(cassiterite)	
Mn	Pyrolusite	$MnO_2$
Cr	Chromite	FeO Cr <sub>2</sub> O <sub>3</sub>
Zn	Zincite	ZnO
Ti	Ilmenite	FeO· TiO <sub>2</sub>
Fe	Haematite	Fe <sub>2</sub> O <sub>3</sub>
	Magnetite	$Fe_3O_4$
Ca	Limestone	CaCO <sub>3</sub>
Mg	Magnesite	MgCO <sub>3</sub>
Zn	Calamine	$ZnCO_3$
Ba	Barytes	BaSO <sub>4</sub>
Ca	Gypsum 🗻	CaSO <sub>4</sub> 2H <sub>2</sub> O
Li	Lepidolite	(Li,Na,K)2Al2(SO4)3(F,OH)2
	Triphylite	(Li,Na) <sub>3</sub> PO <sub>4</sub> · (Fe,Mn) <sub>3</sub> (PO <sub>4</sub> ) <sub>2</sub>
Be	Beryl	3BeO· Al <sub>2</sub> O <sub>3</sub> · 6SiO <sub>2</sub>

#### **METALLURGY**

The whole process of obtaining a pure metal from one of its ores is known as metallurgy.

In order to extract the metals from ores, several physical and chemical methods are used. The method used in a particular case depends upon the nature of the ore, the properties of the metal and the local conditions. Thus, it is not possible to have a universal method for the extraction of all the metals from their ores. However, the metallurgy of a metal involves three main operations:

- (i) Concentration or dressing of the ore.
- (ii) Isolation of the metal in crude state from the concentrated ore.
- (iii) Purification or refining of the crude metal.

## CONCENTRATION OR DRESSING OF THE ORE

The ores usually are obtained after mining in the form of big lumps. These are broken into small pieces with the help of *crushers* or *grinders*. This process is called **crushing**. These pieces are then converted into a fine powder with the help of either a *ball mill* or *stamp mill*. This process is termed **pulverisation**.

The ores usually contain soil, sand, stones and other useless silicates. These undesired impurities present in ores are called **gangue** (pronounced "gang") or **matrix**. The removal of these impurities from the ores is known as **concentration** or **dressing** or **benefaction** of the ore. To separate the useful minerals from the gangue, both physical and chemical methods are used depending on the ore. It can be done in a number of ways depending upon the nature of the impurities.

#### (A) Gravity Separation

This separation is based on the difference in the specific gravities of the gangue particles and the ore particles. The powdered ore is agitated with water or washed with a running stream of water. The heavy ore particles settle down while the lighter particles of sand, clay, etc., are washed away. For this either Wilfley table or hydraulic classifier is used. Wilfley table is a wooden table having a slanting floor on which long wooden strips called riffles are fixed (Fig. 4.4).

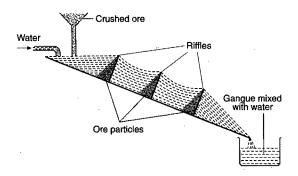

Fig. 4.4 The Wilfley table

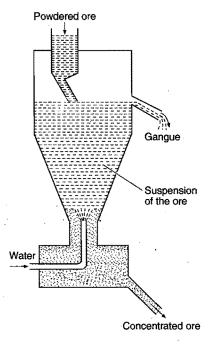

Fig. 4.5 Gravity process

The powdered ore is suspended in a stream of water. The heavier ore particles collect behind the riffles and the gangue particles are carried away with the stream of water. Hydraulic classifier is shown in Fig. 4.5. Powdered ore is dropped from the top of classifier and a strong stream of water is introduced from the bottom. The lighter gangue particles are carried away by the water while the heavier ore particles settle down. Generally, **oxide** and **carbonate ores** are concentrated by this method. For example, tin ore (cassiterite) and iron ore (haematite) are concentrated by gravity method.

#### (B) Electromagnetic Separation

When one component, either the ore or impurity, is magnetic in nature, this method can be used for separation. A magnetic separator consisting a belt moving on two rollers is used, one of which is a strong magnet. The powdered ore is dropped on the belt from one end (non-magnetic) and at the other end (magnetic) the magnetic particles are attracted and fall nearer the roller while non-magnetic particles fall away from the roller. Ferro-magnetic ores are concentrated by this method. For example, wolframite (FeWO<sub>4</sub>)—a magnetic ore, is separated from the non-magnetic ore, cassiterite (SnO<sub>2</sub>) by this method.

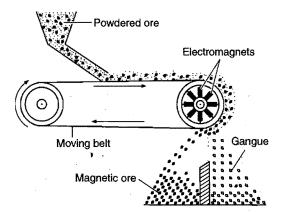

Fig. 4.6 Electromagnetic separation

#### (C) Froth Floatation Process

Froth floatation is a physical method of separating mineral from the gangue that depends on differences in their wettabilities by a liquid solution. This method is used for the concentration of sulphide ores. The method is based on the preferential wetting properties with the frothing agent and water. The powdered ore is added to water containing pine oil (frothing agent) and sodium ethyl xanthate (collecting agent). Cresols and aniline are also added. They act as froth stabilizers. A vigorous stream of air is now passed through, which thoroughly agitates the mixture and disposes the oil into colloid sized particles. As a result of this, the sulphide particles of the ore stick to the oil droplets and rise to the

surface in the form of froth supported by air bubbles. Water wets the gangue particles which sink to the bottom. With this method, it is possible to concentrate the dense ores such as galena and zinc blende.

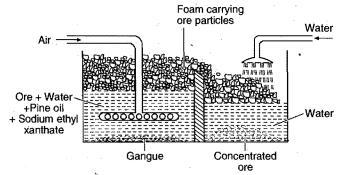

Fig. 4.7 Froth floatation process

Sometimes **depressants** are used to prevent certain type of particles from forming the froth with the bubbles. In the concentration of galena ore, sodium cyanide is added as a depressant for zinc sulphide (ZnS). NaCN forms a layer of zinc complex, Na<sub>2</sub>Zn(CN)<sub>4</sub> on the surface of ZnS and thereby prevents it from the formation of froth while PbS forms a froth. Thus, PbS is separated from ZnS.

#### (D) Leaching

It is a chemical separation. It involves the treatment of the ore with a suitable reagent as to make it soluble while impurities remain insoluble. The insoluble impurities are separated by filteration. The impurities, in this case, include not only gangue but also chemical entities which are not solubilized during leaching operation. The following examples illustrate the procedure.

(i) Leaching of alumina from bauxite ore: Bauxite ore contains ferric oxide, titanium oxide and silica as impurities. When the powdered ore is digested with an aqueous solution (45%) of sodium hydroxide at about 200°C under pressure (35–36 bar), the alumina dissolves forming sodium aluminate while ferric oxide (Fe<sub>2</sub>O<sub>3</sub>), TiO<sub>2</sub> and silica remain as insoluble part.

$$Al_2O_3 \cdot 2H_2O + 2NaOH + H_2O \longrightarrow 2Na[Al(OH)_4]$$
Sodium aluminate (Soluble)

The solution of sodium aluminate is filtered. It may also contain some sodium silicate and free sodium hydroxide. The filtrate is neutralised by passing  $CO_2$  gas, the hydrated  $Al_2O_3$  gets precipitated. At this point, the solution is seeded with freshly precipitated aluminium hydroxide which induces the precipitation.

$$2Na[Al(OH)_4] + 2CO_2 \longrightarrow Al_2O_3 \cdot xH_2O + 2NaHCO_3$$

The sodium silicate remains in the solution and hydrated alumina is filtered, dried and heated to about 1200°C to get pure alumina.

$$Al_2O_3$$
  $xH_2O \xrightarrow{1200$ °C  $Al_2O_3 + xH_2O$ 

[The above process is known as Baeyer's process.]

(ii) Leaching of silver and gold: Gold and silver are extracted from their native ores or silver from argentite ore  $(Ag_2S)$  by leaching. This is also known as Mac-Arthur Forest cyanide process.

In this process, the finely powdered argentite ore or the native silver particles, or the native gold particles are treated with a dilute solution (0.5%) of sodium or potassium cyanide while a current of air is continuously circulated. As a result silver and gold dissolve by forming respective complex cyanides. The impurities remain unaffected. These are filtered off.

$$4Ag + 8NaCN + O_2 + 2H_2O \longrightarrow 2Na[Ag(CN)_2] + 4NaOH$$
 Sodium dicyanoargentate (I) (Soluble) 
$$Ag_2S + 4NaCN \longrightarrow 2Na[Ag(CN)_2] + Na_2S$$
 
$$Na_2S \text{ is largely oxidised to } Na_2SO_4.$$
 
$$4Na_2S + 2H_2O + 5O_2 \longrightarrow 2Na_2SO_4 + 2NaOH + 2S$$
 
$$4Au + 8NaCN + O_2 + 2H_2O \longrightarrow 2Na[Au(CN)_2] + 4NaOH$$
 Sodium dicyanoaurate (I) (Soluble)

Ag or Au is recovered from the solution by the addition of electropositive metal like zinc.

$$2Na[Ag(CN)_2] + Zn \longrightarrow Na_2[Zn(CN)_4] + 2Ag$$

$$2Na[Au(CN)_2] + Zn \longrightarrow Na_2[Zn(CN)_4] + 2Au$$
Sodium tetracyanozincate (II)
(Soluble)

## EXTRACTION OR ISOLATION OF CRUDE METALS (Oxidation/Reduction)

Metals are usually extracted by reduction. Thus, the concentrated ore is converted into a form which is suitable for reduction. Oxides are easier to reduce, therefore, the extraction of metals involves the following two major steps:

- (1) Conversion of the ore into metallic oxide
- (2) Reduction of the metallic oxide to the free metal.

#### Conversion of the ore into metallic oxide

The ores of the metals are usually in the form of hydrated oxides, carbonates, sulphides, etc. Depending upon the nature of the ores, two methods are used for conversion into oxides.

**Note:** The ores which are already in anhydrous form—for example, rutile (TiO<sub>2</sub>)—are not subjected to these methods. After concentration, these are directly reduced.

(A) Calcination: This method is commonly used to convert hydrated oxides or hydroxides and carbonates into respective oxides. It involves heating of the ore below its

**fusion temperature in absence of air.** This step is generally performed in a **reverberatory furnace**. The concentrated ore is put on the hearth of the furnace and heated by flames deflected from the roof. During calcination the following changes may occur.

Moisture is driven out. Water is removed from hydrated oxides or hydroxides. Organic matter is expelled.

$$\begin{array}{ccc} \text{Al}_2\text{O}_3 \cdot 2\text{H}_2\text{O} & \xrightarrow{\text{Heat}} & \text{Al}_2\text{O}_3 + 2\text{H}_2\text{O} \\ \text{Bauxite} & & \text{Alumina} \\ \text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O} & \xrightarrow{\text{Heat}} & \text{Fe}_2\text{O}_3 & + 3\text{H}_2\text{O} \\ \text{Limonite} & & \text{Ferric oxide} \end{array}$$

Carbonates lose carbon dioxide and are converted into corresponding oxides.

$$\begin{array}{c} \text{CaCO}_3 & \xrightarrow{\text{Heat}} & \text{CaO} & + \text{CO}_2 \\ \text{Calcium oxide} & \xrightarrow{\text{Calcium oxide}} & \\ \text{CaCO}_3 \cdot \text{MgCO}_3 & \xrightarrow{\text{Heat}} & \text{CaO} + \text{MgO} & + \text{CO}_2 \\ \text{Dolomite} & & \text{Magnesium oxide} \\ \text{CuCO}_3 \cdot \text{Cu(OH)}_2 & \xrightarrow{\text{Heat}} & \text{2CuO} + \text{H}_2\text{O} + \text{CO}_2 \\ \text{Malachite} & & \text{Cupric oxide} \\ & & \text{ZnCO}_3 & \xrightarrow{\text{Heat}} & \text{ZnO} & + \text{CO}_2 \\ \text{Calamine} & & \text{Zinc oxide} \\ \end{array}$$

The material becomes porous which can be easily reduced in the subsequent step.

- **(B) Roasting:** It is a process in which the ore is heated in presence of air. During this operation, the temperature is kept below the melting point of the ore. The sulphide ores are generally subjected to roasting. The roasting is generally done in a reverberatory furnace or in a small blast furnace. As a result of roasting, the following changes occur.
  - (i) Moisture is driven out.
  - (ii) Organic matter is burnt.
- (iii) The non-metallic impurities such as sulphur, phosphorus, arsenic are converted into respective volatile oxides which get removed.

$$S_8 + 8O_2 \longrightarrow 8SO_2$$
 (Sulphur dioxide)  
 $P_4 + 5O_2 \longrightarrow P_4O_{10}$  (Phosphorus pentoxide)  
 $4As + 3O_2 \longrightarrow 2As_2O_3$  (Arsenious oxide)

Sulphide ores are converted into metallic oxides.

$$2ZnS + 3O_2 \longrightarrow 2ZnO + 2SO_2$$

$$2PbS + 3O_2 \longrightarrow 2PbO + 2SO_2$$

$$Lead oxide$$

$$2Cu_2S + 3O_2 \longrightarrow 2Cu_2O + 2SO_2$$

$$Cuprous oxide$$

The sulphur dioxide thus evolved is utilised for the manufacture of  $H_2SO_4$ .

In the extraction of copper, the ore is copper pyrites (CuFeS<sub>2</sub>) which consists of FeS also. The ore is mixed with silica before roasting. During heating, initially a mixture of Cu<sub>2</sub>S and FeS is formed.

$$2CuFeS_2 \longrightarrow Cu_2S + 2FeS + S$$
$$S + O_2 \longrightarrow SO_2$$

Most of the FeS is converted into FeO which combines with silica to form iron silicate (FeSiO<sub>3</sub>)—a **slag** (fusible in nature).

Copper is obtained in the form of copper matte which contains Cu<sub>2</sub>S and small amount of FeS.

The material becomes porous which can be made easily workable in the subsequent step.

In some cases chlorinating roasting is done as metal is obtained by reduction of halide (usually chloride). For example, silver ores are heated with sodium chloride.

$$Ag_2S + 2NaCl \longrightarrow AgCl + Na_2S$$

**Note:** (i) Calcination and roasting may be carried out in the same reverberatory furnace. During calcination, air holes are partially or completely closed while in roasting, the air holes are open.

(ii) When roasting is done at moderate temperature, the sulphide ore is partially oxidised into oxide and partially into sulphate. For example, in the roasting of galena and zinc blende.

$$\begin{array}{l} \text{2PbS} + 3\text{O}_2 \longrightarrow \text{2PbO} + 2\text{SO}_2 \\ \text{PbS} + 2\text{O}_2 \longrightarrow \text{PbSO}_4 \\ \text{2ZnS} + 3\text{O}_2 \longrightarrow \text{2ZnO} + 2\text{SO}_2 \\ \text{ZnS} + 2\text{O}_2 \longrightarrow \text{ZnSO}_4 \end{array}$$

### 2. Reduction of the metallic oxide to the free metal

The crude metal is obtained when the roasted or calcined ore is put to reduction by using a suitable reducing agent. The selection of a suitable reducing agent depends upon the reactivity of the metal. Some of the methods commonly used to get the free metal from the roasted or calcined ore are briefly described here.

#### (A) Smelting

This involves reduction of ore to the molten metal at a high temperature. For the extraction of less electropositive metals such as Pb, Zn, Fe, Sn, etc., powerful reducing agents such as C, H<sub>2</sub>, CO, water gas, Na, K, Mg, Al may be used. Some examples are given below:

$$PbO + C \longrightarrow Pb + CO$$

$$WO_3 + 3H_2 \longrightarrow W + 3H_2O$$

$$CuO + CO \longrightarrow Cu + CO_2$$

$$Cr_2O_3 + 2Al \longrightarrow 2Cr + Al_2O_3$$

The process of extracting the metal by heating the metal oxide with a suitable reducing agent is called pyrometallurgy.

Out of the various reducing agents, carbon, carbon monoxide and aluminium are generally used.

**(i) Carbon reduction process:** It is generally called **smelting.** The oxides of less electropositive metals are reduced by strongly heating them with coal or coke. Carbon combines with the oxygen of the metal oxide to form carbon monoxide which can also act as a reducing agent.

$$M_x O_y + y C \longrightarrow x M + y CO$$

$$PbO + C \longrightarrow Pb + CO$$

$$PbO + CO \longrightarrow Pb + CO_2$$
Similarly,
$$Fe_2 O_3 + 3C \longrightarrow 2Fe + 3CO$$

$$Fe_2 O_3 + 3CO \longrightarrow 2Fe + 3CO_2$$

The ores, even after concentration, contain some gangue. To remove gangue, certain substances are mixed with concentrated ore which combine with the gangue to form a fusible material which is not soluble in molten metal. The substances used are called **fluxes** and the fusible material formed during reduction process is called **slag**. Slag is usually lighter and floats on the surface of the molten metal.

Fluxes are classified as (i) Acidic flux and (ii) Basic flux. An acidic flux (e.g., silica, borax, etc.,) is the chemical substance which removes the basic impurities.

$$SiO_2$$
 +  $CaO$   $\longrightarrow$   $CaSiO_3$   
Acidic flux Basic impurity Slag  
(Gangue)

The basic flux (e.g., limestone, magnesite, ferric oxide, etc.,) is the chemical substance which removes the acidic impurities.

$$MgCO_3$$
 +  $SiO_2$   $\longrightarrow$   $MgSiO_3$  +  $CO_2$   
Basic flux Acidic impurity  $Slag$  (Gangue)

(ii) Reduction by aluminium (Goldschmidt aluminothermic process): This process is employed in the case of those metals which have very high melting points and are to be extracted from their oxides. Their reduction with carbon

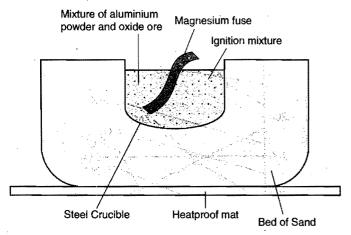

Fig. 4.8 An apparatus for thermite reaction

is not satisfactory. A mixture of concentrated oxide ore and aluminium powder, commonly called as **thermite**, is taken in a steel crucible placed in a bed of sand. The reaction is started by the use of an ignition mixture containing magnesium powder and barium peroxide.

$$Cr_2O_3 + 2Al \longrightarrow 2Cr + Al_2O_3$$

$$3Mn_3O_4 + 8Al \longrightarrow 9Mn + 4Al_2O_3$$

Large amount of heat energy is released during reduction, which fuses both the alumina and the metal.

#### (B) Self Reduction Process

This process is also called autoreduction process or air reduction process. The sulphide ores of less electropositive metals like Hg, Pb, Cu, etc., are heated in air as to convert part of the ore into oxide or sulphate which then reacts with the remaining sulphide ore to give the metal and sulphur dioxide. No external reducing agent is used in this process.

$$\begin{array}{c} 2 HgS + 3 O_2 \longrightarrow 2 HgO + 2 SO_2 \\ 2 HgO + HgS \longrightarrow 3 Hg + SO_2 \end{array} \end{array} \begin{array}{c} \text{Extraction of Hg} \\ \text{from cinnabar ore} \end{array}$$
 
$$\begin{array}{c} 2 Cu_2S + 3O_2 \longrightarrow 2 Cu_2O + 2 SO_2 \\ Cu_2S + 2 Cu_2O \longrightarrow 6 Cu + SO_2 \end{array} \end{array} \begin{array}{c} \text{Extraction of Cu} \\ \text{from copper glance} \end{array}$$
 
$$\begin{array}{c} 2 PbS + 3O_2 \longrightarrow 2 PbO + 2 SO_2 \\ 2 PbO + PbS \longrightarrow 3 Pb + SO_2 \end{array} \end{array} \begin{array}{c} \text{Extraction of lead} \\ \text{from galena ore} \end{array}$$

#### (C) Electrolytic Reduction

The oxides of the highly electropositive metals like Na, K, Mg, Ca, Al, etc., cannot be reduced easily with carbon at moderate temperatures. For reduction, a very high temperature is required at which the metal may combine with carbon to form a carbide. These metals are thus extracted by the electrolysis of their oxides, hydroxides or chlorides in fused state. Sometimes, a small amount of some other salt is

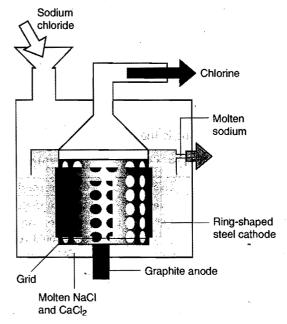

Fig. 4.9 Production of sodium metal from fused mixture of NaCl and CaCl<sub>2</sub> by Electrolytic reduction by the Down's process

added to lower the fusion temperature or to increase the conductivity or both. The metal is liberated at the cathode. Sodium is obtained by the electrolysis of fused mixture of NaCl and CaCl<sub>2</sub> (**Down's process**) or by electrolysis of fused sodium hydroxide (**Castner's process**).

NaCl
$$\uparrow | Fused$$
Cathode  $\longleftarrow$  Na<sup>+</sup> + Cl<sup>-</sup>  $\longrightarrow$  Anode
$$Na^{+} + e \longrightarrow Na \qquad Cl^{-} - e = Cl$$

$$2Cl \longrightarrow Cl_{2}$$

Aluminium is obtained by the electrolysis of alumina mixed with cryolite.

### THERMODYNAMIC PRINCIPLES OF METALLURGY

The basic concepts of thermodynamics are quite helpful in selecting which element will be the most suitable reducing agent for a particular oxide during a metallurgical operation. It can also predict the optimum temperature at which the reduction can occur smoothly.

For any reaction or process, Gibb's Helmholtz free energy change ( $\Delta G$ ) is given by the equation,

$$\Delta G = \Delta H - T \Delta S \qquad \dots (i)$$

where  $\Delta H$  is the enthalpy change and  $\Delta S$  is the entropy change and T is the absolute temperature at which the reaction is carried out. For the feasibility of any reaction at any temperature the value of  $\Delta G$  must be negative at that temperature. The free energy change is also related to the equilibrium constant 'K' of the reaction at temperature T by the following equation,

$$\Delta G = -RT \ln K$$
 ... (ii)

A negative  $\Delta G$  implies a +ve K in the above equation. This can happen only if the reaction proceeds towards the products. The following conclusions can be drawn:

(i) Greater the negative value of free energy change ( $\Delta G$ ), more spontaneous is the reaction.

#### CONDITIONS FOR $\Delta G$ TO BE NEGATIVE

ΔΗ	ΤΔS	Favourable conditions
- ve (Exothermic)	+ ve	Any temperature
<ul><li>ve (Exothermic)</li></ul>	– ve	$\Delta H > T \Delta S$
		(Temp. should be low)
+ ve (Endothermic)	+ ve	$T\Delta S > \Delta H$
		(Temp. should be high)

(ii) If two reactions are put together in a system and the net  $\Delta G$  of both the reactions is –ve, the overall reaction will occur, *i.e.*, a reaction with  $\Delta G$  positive can be made to occur if it is coupled with another reaction having a large negative  $\Delta G$  so that the net  $\Delta G$  of both the reactions is negative.

Such coupling reactions can be easily understood through **Ellingham diagram.** 

#### **Ellingham Diagram**

Ellingham diagram consists of graphs which represent the variation of standard free energy with temperature of the formation of oxides of various elements, *i.e.*, plots of  $\Delta_f G^\circ vs$  T. Similar plots can also be plotted for sulphides and halides. These were first plotted by H.J.T. Ellingham. These diagrams help us in predicting the feasibility of thermal reduction of an ore.

Consider the formation of a metal oxide  $(M_xO)$ .

$$2xM(s) + O_2(g) \longrightarrow 2M_xO(s)$$

In this reaction, there is decrease in the value of  $\Delta S^{\circ}$  as  $M_xO$  is solid and  $O_2$  is a gas, *i.e.*,  $\Delta S$  is negative. Thus, if temperature is increased,  $T\Delta S^{\circ}$  becomes more negative.

As in the equation,

$$\Delta G^{\circ} = \Delta H^{\circ} - T \Delta S^{\circ}$$

 $T\Delta S^{\circ}$  is subtracted, therefore,  $\Delta G^{\circ}$  becomes less negative, *i.e.*,  $\Delta G^{\circ}$  is likely to increase with rise in temperature and this trend is confirmed from the curves of metal oxides in Fig. 4.10. The following observations are made from the curves.

- (i) The slope of the curves of the formation of metal oxides is +ve because  $\Delta G^{\circ}$  becomes less negative or increases with the rise in temperature.
- (ii) Each curve is a straight line except when some change takes place in phase  $(s \longrightarrow l \text{ or } l \longrightarrow g)$ . The temperature at which such a change occurs is indicated by an increase in the slope on the +ve side. For example, in the Zn—ZnO curve, the melting of zinc is indicated by an abrupt increase in the +ve slope at temperature 692 K.

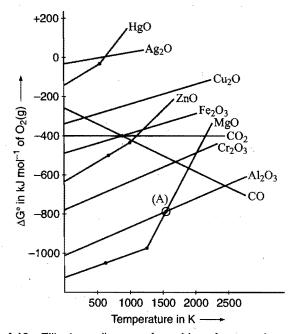

Fig. 4.10 Ellingham diagrams for oxides of some elements

(iii) In the case of less reactive metals like silver and mercury,  $\Delta G^{\circ}$  becomes positive at high temperatures. It indicates that both silver oxide (Ag<sub>2</sub>O) and mercury oxide (HgO) are unstable and decompose at high temperature.

$$2Ag_2O \xrightarrow{\text{Heat}} 4Ag + O_2$$

$$2HgO \xrightarrow{\text{Heat}} 2Hg + O_2$$

- (iv) In the curve of CO,  $\Delta G^{\circ}$  decreases as  $\Delta S^{\circ}$  increases. This is indicated by the downward trend.
- (v) Any metal oxide with lower value of  $\Delta G^{\circ}$  is more stable than a metal oxide with higher  $\Delta G^{\circ}$ . This implies that the metal oxide placed higher in the diagram can be reduced by the metal involved in the formation of the oxide placed lower in the diagram. For example,  $\operatorname{Cr_2O_3}$  can be reduced by Al metal but  $\operatorname{Al_2O_3}$  cannot be reduced by Cr.

$$Cr_2O_3 + 2Al \longrightarrow Al_2O_3 + 2Cr$$

Thus, the relative tendency of the various metals to act as reducing agents is:

#### Limitations of Ellingham Diagram

Ellingham diagram simply tells whether the reduction of a particular oxide with a specific reducing agent is possible or not. However, it does not tell anything about the kinetics of the reduction process, *i.e.*, whether the reduction is fast or slow.

The interpretation of  $\Delta G^{\circ}$  is based on the equilibrium constant, 'K'.

$$\Delta G^{\circ} = -RT \ln K$$

Thus, it is presumed that the reactants and products are in equilibrium:

$$M_rO + A \Longrightarrow xM + AO$$

But, this is not always true because the reactant/product may be solid.

#### Reducing Nature of Carbon

Carbon in the form of coke, charcoal or carbon monoxide is used as a reducing agent in pyrometallurgical operations. Such a reduction process used in the extraction of a metal is termed **smelting**.

When carbon is to act as a reducing agent, the following three reactions are possible:

$$C(s) + O_2(g) \longrightarrow CO_2(g)$$
 ... (i)

$$2C(s) + O_2(g) \longrightarrow 2CO(g)$$
 ... (ii)

$$2CO(s) + O_2(g) \longrightarrow 2CO_2(g)$$
 ... (iii)

In the first reaction (formation of CO<sub>2</sub>) there is hardly any change in entropy, *i.e.*,  $\Delta S^{\circ} \approx 0$  and therefore,  $\Delta G^{\circ}$  remains

nearly the same with rise in temperature, i.e.,  $\Delta G^{\circ}$  is independent of temperature.

In the second reaction (formation of CO), there is increase in entropy ( $\Delta S^{\circ}$  is positive) and therefore,  $\Delta G^{\circ}$  becomes more negative with increase in temperature.

However, in third reaction, there is decrease in entropy ( $\Delta S^{\circ}$  is negative) and therefore,  $\Delta G^{\circ}$  becomes less negative with increase in temperature.

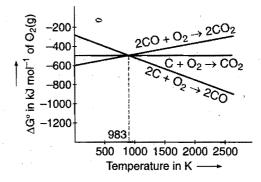

Fig. 4.11 Ellingham diagram for the reducing nature of carbon

The above observations can be seen in Fig. 4.11. The three curves have been found to intersect at 983 K. It implies that above this temperature, the reaction (ii) is most suitable. It means that carbon can reduce any metal oxide at very high temperatures and is then itself oxidised to CO. However, the reduction with carbon at high temperatures is not preferred in all cases due to the following reasons:

- (a) It involves high cost.
- (b) Some metals react with carbon at high temperatures and form carbides.
- (c) There are many practical difficulties in the maintenance of high temperature.

From the plot for the reaction of carbon monoxide with oxygen, it is evident that carbon monoxide acts as a better reducing agent than carbon at temperatures below 983 K.

#### Theory of Reduction of Metal Oxide with Carbon

During reduction the metal oxide decomposes,

$$M_xO(s) \longrightarrow xM(s \text{ or } l) + 1/2 O_2(g)$$
 ... (i)

and the carbon (reducing agent) takes away the oxygen, *i.e.*, it undergoes **oxidation**.

$$C(s) + 1/2 O_2(g) \longrightarrow CO(g)$$
 ... (ii)  
 $\Delta G^{\circ}(C, CO)$ 

or 
$$1/2 C(s) + 1/2 O_2(g) \longrightarrow 1/2 CO_2(g)$$
 ... (iii)  
 $1/2 \Delta G^{\circ}(C, CO_2)$ 

or 
$$CO(g) + 1/2 O_2(g) \longrightarrow CO_2(g)$$
 ... (iv)

$$\Delta G^{\circ}(C, CO_2)$$
 he role of the reducing agent is to provide a large

The role of the reducing agent is to provide a large negative  $\Delta G^{\circ}$  to make the sum of the  $\Delta_r G^{\circ}$  of the above

two reactions, (i.e., reduction of metal oxide and oxidation of carbon or carbon monoxide) negative.

Reversing the equation (i)

$$xM(s \text{ or } l) + 1/2 O_2(g) \longrightarrow M_xO(s)$$
 ... (v)  
 $\Delta G^{\circ}(M, M_xO)$ 

Subtracting equation (v) from equations (ii), (iii) and (iv) respectively, we have,

$$M_xO(s) + C(s) \longrightarrow xM(s \text{ or } l) + CO(g)$$
 ... (vi)  
 $M_xO(s) + 1/2 C(s) \longrightarrow xM(s \text{ or } l) + 1/2CO_2(g)$  ... (vii)  
 $M_xO(s) + CO(s) \longrightarrow xM(s \text{ or } l) + CO_2(g)$  ... (viii)

The equations (vi), (vii) and (viii) describe the reduction of the metal oxide,  $M_x$ O. The  $\Delta_r$ G° values of these equations can be obtained from Ellingham diagram (Fig. 4.10). If  $\Delta_r$ G° values are negative, the reduction is feasible otherwise not. Greater the difference, easier is the reduction.

Without making any calculations for  $\Delta_r G^\circ$ , the prediction about the feasibility of a reduction process can be made by looking at the Ellingham diagram. Metal oxide placed higher in the diagram can be reduced by the element (metal) involved in the formation of the oxide placed lower in the diagram.

It is important to note that if a particular reduction process does not take place at a lower temperature, it may take place at a higher temperature. Ellingham diagram also helps in selecting such a temperature. The temperature is indicated by the intersection of the two curves. For example, the temperature at the intersection point 'A' in Fig 4.10 of two curves for Al  $\longrightarrow$  Al<sub>2</sub>O<sub>3</sub> and Mg  $\longrightarrow$  MgO is approximately 1665 K. Below this temperature Mg reduces Al<sub>2</sub>O<sub>3</sub> into Al but above 1665 K, Al can reduce MgO into Mg.

# 4.7 APPLICATIONS OF ELLINGHAM DIAGRAM IN PYROMETALLURGY

The utility of Ellingham diagram in pyrometallurgy can be illustrated by discussing the extraction of iron, copper and zinc from their respective oxides.

#### (A) Theory of reduction of Haematite

In the Ellingham diagram (Fig. 4.12), there are three curves which illustrate the formation of ferric oxide from iron,

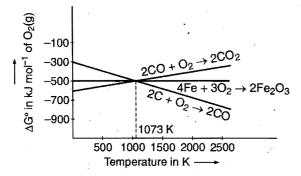

Fig. 4.12 Ellingham diagram for the reduction of haematite

formation of CO from carbon and formation of  $CO_2$  from CO. The curves cross each other at 1073 K.

Above 1073 K,  $\Delta G^{\circ}$  for the formation of Fe<sub>2</sub>O<sub>3</sub> is less negative than  $\Delta G^{\circ}$  for the formation of carbon monoxide from carbon. Thus, above 1073 K, carbon (coke) can reduce Fe<sub>2</sub>O<sub>3</sub>, *i.e.*,  $\Delta_r G^{\circ}$  for the reaction,

$$Fe_2O_3(s) + 3C(s) \xrightarrow{> 1073 \text{ K}} 2Fe(s) + 3CO(g)$$
 is negative.

Below 1073 K,  $\Delta G^{\circ}$  for formation of CO from carbon is less negative than  $\Delta G^{\circ}$  for the formation of Fe<sub>2</sub>O<sub>3</sub>.  $\Delta_r G^{\circ}$  for the reduction of Fe<sub>2</sub>O<sub>3</sub> with carbon will be positive and hence, reduction is not possible. However, it is observed from the diagram that  $\Delta G^{\circ}$  of formation of CO<sub>2</sub> from CO is more negative than  $\Delta G^{\circ}$  of formation of Fe<sub>2</sub>O<sub>3</sub>. This means that Fe<sub>2</sub>O<sub>3</sub> can be reduced by CO below 1073 K, *i.e.*,  $\Delta_r G^{\circ}$  for the reaction,

Fe<sub>2</sub>O<sub>3</sub>(s) + 3CO(s) 
$$\xrightarrow{> 1073 \text{ K}}$$
 2Fe(s) + 3CO<sub>2</sub>(g) is negative.

Thus, in the blast furnace, reduction of  $Fe_2O_3$  occurs in different temperature ranges either below 1073 K by carbon monoxide or above 1073 K by carbon (coke).

#### (B) Theory of reduction of Cu<sub>2</sub>O

#### (i.e., Extraction of copper from cuprous oxide)

In the Ellingham diagram (Fig. 4.13), it is observed that  $Cu_2O$  curve lies almost at the top while the lines showing the formation of  $CO_2$  from C and CO and the formation of CO from carbon lie much below it. So it is quite easy to reduce  $Cu_2O$  to the metal by heating with coke at temperatures after 500–600 K.

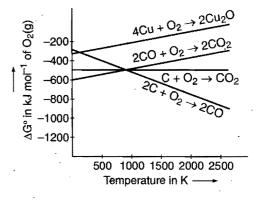

Fig. 4.13 Ellingham diagram for copper and carbon oxides

However, most of the ores of copper are sulphides and contain iron sulphide also. Thus, the ores are first roasted in such a way so that iron is removed and copper sulphide is converted into cuprous oxide.

$$2Cu_2S + 3O_2 \longrightarrow 2Cu_2O + 2SO_2$$

The oxide can then be easily reduced to metallic copper by using coke.

$$Cu_2O + C \longrightarrow 2Cu + CO$$

However, this method is not used in actual practice for the extraction of copper.

#### (C) Theory of reduction of ZnO

Ellingham diagram (Fig. 4.14) reveals that the curves involving the formation of ZnO and carbon monoxide cross each other at about  $1270~\rm{K}$ .

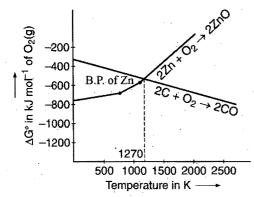

Fig. 4.14 Ellingham diagram for formation of ZnO and CO

There is a sudden increase in the value of  $\Delta G^{\circ}$  for the formation of ZnO above 1180 K. This is due to the fact that zinc begins to boil at this temperature. Above 1270 K,  $\Delta_r G^{\circ}$  of the following equation,

 $ZnO(s) + C(s) \xrightarrow{> 1270 \text{ K}} Zn(g) + CO(g)$  is considerable negative and thus, reduction of ZnO with coke occurs easily.

## 4.8 THIRD OPERATION—REFINING OR PURIFICATION

The metals obtained by the application of above reduction methods from the concentrated ores are usually impure. These impure metals may be associated with small amounts of (a) unchanged ore, (b) other metals produced by the simultaneous reduction of their compounds originally present in the ore, (c) non-metals like silicon, carbon, phosphorus, etc., (d) residual slag, flux, etc. The impure metal is thus subjected to some purifying processes known as refining in order to remove the undesired impurities. The following refining processes may be applied depending upon the nature of the metal under treatment and the nature of the impurities.

- (a) Liquation process: This process is based on the difference in fusibility of the metal and impurities. When the impurities are less fusible than the metal itself, this process is employed. The impure metal is placed on the sloping hearth of a furnace and gently heated. The metal melts and flows down leaving behind the impurities on the hearth. This method is used to purify the metals like Bi, Sn, Pb, Hg, etc.
- **(b) Distillation:** This process is used for those metals which are easily volatile. The impure metal is heated in a retort and its vapours are separately condensed in a receiver.

The non-volatile impurities are left-behind in the retort. This is used for the purification of Zn, Cd, Hg, etc.

- **(c) Pyrometallurgical oxidation process:** This process is used when the impurities have a greater affinity for oxygen than the metal itself. This method is usually employed for refining the metals like Fe, Cu, Ag, etc. The oxidation is done by various ways.
- (i) Cupellation: The impure metal is heated in a cupel or oval shaped crucible made of bone ash or cement and a blast of air is passed over the molten mass. The impurities get oxidised and removed with the blast of air. For example the impurity of lead present in silver is removed by cupellation process.
- (ii) Bessemerisation: The impure metal is heated in a furnace and a blast of compressed air is blown through the molten mass. The impurities get oxidised. For example, the molten pig iron is taken in a bessemer converter and compressed air is passed which oxidises the impurities.

$$\begin{array}{c} 2Mn + O_2 & \longrightarrow 2MnO \\ Si + O_2 & \longrightarrow SiO_2 \\ 2C + O_2 & \longrightarrow 2CO \\ MnO + SiO_2 & \longrightarrow MnSiO_3 \\ Slag \end{array}$$

- (iii) Poling: The impure metal containing oxides as impurity can be purified by this method. The molten impure metal is stirred with green poles of wood. The green poles of wood release the hydrocarbon gases which reduce the oxide impurities. This method is especially used in the purification of copper (old method).
- (d) Electrolytic refining of metals: Many of the metals such as copper, silver, gold, aluminium, lead, etc., are purified by this method. This is perhaps the most important method. The impure metal is made anode while a thin sheet of pure metal acts as a cathode. The electrolytic solution consists of generally an aqueous solution of a salt or a complex of the metal. On passing the current, the pure metal is deposited on the cathode and equivalent amount of the metal gets dissolved from the anode. Thus, the metal is transferred from anode to cathode through solution. The soluble impurities pass into the solution while the insoluble one, especially less electropositive impurities collect below the anode as anodic mud or anode sludge. Some examples are given below:

#### (i) Purification of copper

Impure metal—Anode;

Thin sheets of copper Cathode.

Electrolyte—An aqueous solution of copper sulphate containing H<sub>2</sub>SO<sub>4</sub>.

A current of 1.3 volt is used. Anodic mud contains Ag, Au, Pt, Pd, etc., and impurities like Fe, Zn, Ni, etc., pass into the solution. 99.9% pure copper is obtained.

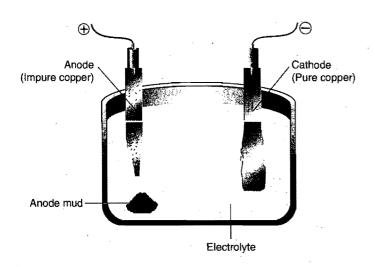

Fig. 4.15 Purification of copper by electrolysis

#### (ii) Purification of silver

Impure metal—Anode; A thin sheet of pure silver—Cathode. Electrolyte—An aqueous solution of AgNO<sub>3</sub> containing HNO<sub>3</sub>.

#### (iii) Purification of lead

Impure metal—Anode; A sheet of pure lead—Cathode. Electrolyte—A solution of lead silico fluoride PbSiF<sub>6</sub> containing 8–10% of H<sub>2</sub>SiF<sub>6</sub>.

- **(e) Special methods:** Sometime some special methods are used for refining or purification of metals, some of which are given below:
- (i) Mond's process: Nickel is purified by this method. Impure nickel is treated with carbon monoxide at 60–80°C when volatile compound, nickel carbonyl, is formed. Nickel carbonyl decomposes at 180°C to form pure nickel and carbon monoxide which can again be used.

Impure nickel + CO 
$$\xrightarrow{60-80^{\circ}\text{C}}$$
 Ni(CO)<sub>4</sub>  $\xrightarrow{180^{\circ}\text{C}}$  Ni + 4CO Gaseous compound

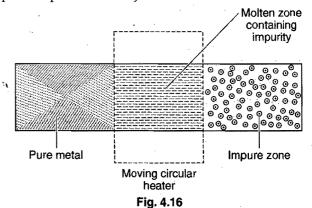

(ii) Van Arkel process: This method is generally applied for obtaining ultrapure metals. The impure metal is converted into a volatile compound while the impurities are not affected. The volatile compound is then decomposed electrically to get the pure metal.

Ti, Zr, Hf, Si, etc., have been refined by this method.

Impure metal + 
$$I_2$$
  $\longrightarrow$  Metal iodide  $\xrightarrow{\text{Tungsten}}$   $\xrightarrow{\text{filament}}$  Metal +  $I_2$   $\xrightarrow{\text{(Pure)}}$   $\xrightarrow{\text{Ti}(s)}$  +  $2I_2(g)$   $\xrightarrow{523 \text{ K}}$   $\xrightarrow{\text{Ti}I_4(g)}$   $\xrightarrow{\text{Impure}}$  Ti $I_4(g)$   $\xrightarrow{\text{Ti}I_4(g)}$   $\xrightarrow{\text{Ti}I_4(g)}$ 

This method is quite expensive.

(iii) Zone refining or Fractional crystallisation: Elements such as Si, Ge, Ga, etc., which are used as semiconductors are refined by this method. Highly pure metals are obtained. The method is based on the difference in solubility of impurities in molten and solid state of the metal. A movable heater is fitted around a rod of the impure metal. The heater is slowly moved across the rod. The metal melts at the point of heating and as the heater moves on from one end of the rod to the other end, the pure metal crystallises while the impurities pass on the adjacent melted zone.

Different metallurgical processes can be broadly divided into three main types.

- **1. Pyrometallurgy:** Extraction is done using heat energy. The metals like Cu, Fe, Zn, Pb, Sn, Ni, Cr, Hg, etc., which are found in nature in the form of oxides, carbonates, sulphides are extracted by this process.
- **2. Hydrometallurgy**: Extraction of metals involving aqueous solution is known as hydrometallurgy. Silver, gold, etc., are extracted by this process.
- **3. Electrometallurgy**: Extraction of highly reactive metals such as Na, K, Ca, Mg, Al, etc., by carrying electrolysis of one of the suitable compound in fused or molten state.

#### **SUMMARY OF THE EXTRACTION OF METALS**

Metal	Main Occurrence	Main Method of Extraction
Sodium	Common Salt, NaCl	Electrolysis of fused NaCl with CaCl <sub>2</sub>
Magnesium	Carnallite, KCl·MgCl <sub>2</sub> ·6H <sub>2</sub> O; Magnesite, MgCO <sub>3</sub>	Electrolysis of fused MgCl2 with KCl
Calcium	Limestone, CaCO <sub>3</sub> ; Gypsum, CaSO <sub>4</sub> ·2H <sub>2</sub> O	Electrolysis of fused CaCl2 and CaF2
Aluminium	Bauxite, Al <sub>2</sub> O <sub>3</sub> 2H <sub>2</sub> O	Electrolysis of Al <sub>2</sub> O <sub>3</sub> in molten Na <sub>3</sub> AlF <sub>6</sub> (cryolite)
Copper	Copper pyrites, CuFeS <sub>2</sub>	Partial oxidation of sulphide ore
	Cuprite, Cu <sub>2</sub> O	$(2Cu2O + Cu2S \longrightarrow 6Cu + SO2)$
Silver	Argentite, Ag <sub>2</sub> S	Hydrometallurgy
	Native silver	$Ag_2S + 4NaCN \longrightarrow 2NaAg(CN)_2 + Na_2S$
		$2NaAg(CN)_2 + Zn \longrightarrow Na_2Zn(CN)_4 + 2Ag$
Zinc	Zinc blende, ZnS	Reduction of ZnO with carbon or electrolysis of ZnSO <sub>4</sub>
	Calamine, ZnCO <sub>3</sub>	$ZnO + C \longrightarrow Zn + CO$
Lead	Galena, PbS	Reduction of PbO with carbon
		$PbO + C \longrightarrow Pb + CO$
Tin .	Cassiterite, SnO <sub>2</sub>	Reduction of SnO <sub>2</sub> with carbon
		$SnO_2 + 2C \longrightarrow Sn + 2CC$
Iron	Haematite, Fe <sub>2</sub> O <sub>3</sub>	Reduction of oxide with carbon monoxide
	Magnetite, Fe <sub>3</sub> O <sub>4</sub>	$Fe_2O_3 + 3CO \longrightarrow 2Fe + 3CO_2$
Chromium	Chromite, FeO Cr <sub>2</sub> O <sub>3</sub>	Reduction of Cr <sub>2</sub> O <sub>3</sub> with Al
		$Cr_2O_3 + 2Al \longrightarrow 2Cr + Al_2O_3$
Nickel	Millerite, NiS	Reduction of NiO with CO
		$NiO + 5CO \longrightarrow Ni(CO)_4 + CO_2; Ni(CO)_4 \longrightarrow Ni + 4CO$
Mercury	Cinnabar, HgS	Direct reduction of HgS by heat alone
· · · · ·		$HgS + O_2 \longrightarrow Hg + SO_2$

### 4.9 FURNACES

Furnace is a device in which high temperature is produced either by burning a fuel or by using electricity. Several types of furnaces are used in the extraction of metals. The important ones are described below:

#### 38 (i) Reverberatory Furnace

This is the kind of a furnace in which fuel does not come in direct contact with the charge. The flames are deflected

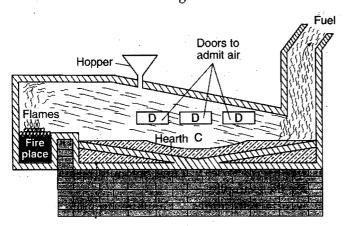

Fig. 4.17 Reverberatory furnace

from the roof of the furnace to the charge undergoing reaction. Thus, this furnace can be used for reduction as well as for oxidation purposes.

The furnace consists of three main parts namely fire place, hearth and chimney. The fire place is built at one end of the furnace at slightly lower level than that of the hearth. The roof is made slanting and connects with the chimney on the other end. The hot gases from the fire place are reflected by the concave ceiling over the hearth. The furnace is surrounded on all sides by walls of fire bricks. Air supply can be controlled by vents and direct blast.

The furnace is used for smelting (reduction) and roasting of the ores. The reduction is done by the use of some suitable reducing agent. The furnace is used (a) for reducing the roasted tin stone  $(SnO_2)$  to molten tin metal by the use of coke, (b) for roasting the galena ore (PbS) as to convert it into PbO and PbSO<sub>4</sub> by the use of air, (c) for roasting of copper pyrites  $(CuFeS_2)$  as to convert it into  $Cu_2O$  and FeO by means of air.

#### (ii) Blast Furnace

Iron ore is converted to iron in a special type furnace, called **blast furnace** (fig. 4.18). It is a huge chimney like structure which can be between 25 and 60 metres in height and 5 to 10 metres in diameter. It is constructed of steel plates

and the inner regions lined with fire-bricks. It has a double cup and cone arrangement at the top for the introduction of charge. Preheated air at a temperature of about 600°C is injected into the furnace through a number of pipes called tuyeres in the bottom of the furnace. It is provided with two tap holes plugged with clay; molten metal is tapped from the lower one and molten slag from the other. The temperature range in the furnace is from 1600°C at the bottom and 200–300°C at the top. Carbon and carbon monoxide reduce the metallic oxides to the free metals.

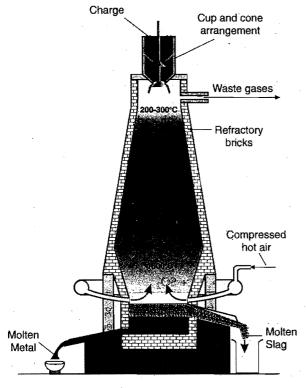

Fig. 4.18 Blast furnace

Blast furnace is frequently used for the extraction of iron and copper from their ores. Slag formation plays an important role in the blast furnace as it covers the melted metal and thus protects the metal from being reoxidised.

#### (iii) Muffle Furnace

This furnace is used when high temperature is required and the fuel and its products of combustion are not to be desired to come into contact with the material to be heated. The muffle is a chamber made of refractory material. The muffle is surrounded by hot flames and hot gases all

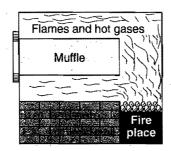

Fig. 4.19 Muffle furnace

around. In an electric muffle furnace the closed chamber is surrounded by heating electric coils. Such a furnace is used for the extraction of zinc, for annealing of gold and silver assaying.

#### (iv) Electric Furnaces

In these furnaces, electrical energy is converted into heat energy. Such furnaces are largely used where cheap power is available and very high temperatures are required and also for carrying electrolytic reduction. The electric furnaces are generally of three types:

- (a) Induction furnace,
- (b) Arc furnaces and
- (c) Resistance furnace.
- (a) Induction furnace: In this furnace the charge lying on the furnace bed or in a crucible constitute the secondary coil of an induction unit and the induced currents produced by making and breaking the primary circuit, heat up the material.
- **(b) Arc furnaces :** Heat is generated by arcs and a temperature over 3000°C may be obtained. Carbon electrodes are used to carry the current and an arc is struck between them and the charge. Arc furnaces are of two types:
  - (i) Direct heat and
  - (ii) Indirect heat.

In the direct heat arc furnaces, arc is used to heat up a gas in which the arc is burning and in indirect heat arc furnace, the arc burns above the charge, *i.e.*, the arc radiates heat towards the charge.

(c) Resistance furnace: Heat is generated by the resistance in the electric circuit. In some cases the material forming the charge may act as the resistance and in other cases, the body of furnace is made up of resistance material and this material cause heating. In some cases, rods of poorly conducting materials are embedded into the charge which become intensely hot on passage of the current.

### 4.10 REFRACTORY MATERIALS

The materials which can withstand very high temperatures without melting or becoming soft are known as refractory materials. These are not affected by slags formed during the extraction of metals. These are used in the form of bricks for the internal linings of furnaces. Refractory materials used are of three types:

- (i) Acid refractories: Silica, quartz, silicious sand stones, etc., are the examples.
- (ii) Basic refractories: Lime, dolomite, magnesite, etc., are the examples.
- (iii) Neutral refractories: Graphite, chromite, bone ash, etc., are the examples.

Silica (92% SiO2, 2.7% Al2O3) and quartz can tolerate

temperatures upto about 1750°C, bauxite upto 1800°C, alumina upto 2000°C and magnesite, chromite, etc., upto

2200°C. Some carbides such as silicon carbide is used as refractory for special purposes.

### MINERAL RESOURCES OF INDIA

Mineral resources of a country determine the economic position of the country. The country which is rich in mineral resources is definitely a prosperous country. India has large mineral resources but not too large in view of the country's huge size and population. India has abundant reserves of coal, mica ore, manganese ore, iron ore, aluminium ore, titanium ore, etc., but particularly poor in non-ferrous metals. A short description of the important metals found in India is given here.

- 1. Iron: India contains some of the world's largest reserves of iron ore, mainly haematite and magnetite. India holds the sixth position regarding the production of iron ore in the world. Large deposits have been reported in Bihar, Jharkhand, Orissa, Madhya Pradesh, Karnataka, Andhra Pradesh and Goa. The states of Orissa and Jharkhand [Singhbhum (Jharkhand); Keonjhar, Sonai and Mayurbhanj (Orissa)] produce over 75% of the total iron ore produced in India. The important steel plants are located at Bhilai, Durgapur, Rourkela, Jamshedpur, Bhadravati and Burnpur.
- Manganese: India possesses large reserves of manganese ore mainly pyrolusite (MnO<sub>2</sub>). India holds the fourth position in the production of manganese ore in the world. Orissa is the leading producer followed by Karnataka, Madhya Pradesh and Maharashtra.
- 3. Aluminium: India is rich in bauxite reserves. Workable deposits are found in Jharkhand, Madhya Pradesh, Tamil Nadu, Maharashtra, Karnataka, Orissa and Gujarat. The availability of cheap power is a must

- for the development of aluminium industry in India.
- 4. Copper: The known copper ore deposits in India are meagre. Almost all the present production of copper ore comes from Singhbhum and Hazaribagh districts of Jharkhand and Khetri of Rajasthan
- 5. Gold: India has very meagre gold reserves. The only gold mine is at Kolar in Karnataka state. It is one of the deepest mines of the world.
- Chromium: Chromite (FeO Cr<sub>2</sub>O<sub>3</sub>) is the chief ore of chromium. It is mainly found in Orissa, Jharkhand, Mysore and Maharashtra.
- 7. **Barium:** Barytes is the main ore of barium. It is mainly found in Andhra Pradesh, Rajasthan and Tamil Nadu.
- 8. Lead and Zinc: India has no important deposits of lead and zinc ores. Recently lead and zinc ores have been found at Zawar mines near Udaipur and at Hazaribagh (Jharkhand). Zawar deposits contain 8–10% Zn and 5% lead.
- Calcium: The sulphate ore of calcium (gypsum) is mainly found in Rajasthan. Limestone and marble (calcium carbonate) are found in large amounts in almost all the states of India.
- 10. Titanium: The principal ore of titanium is ilmenite. It is mainly found in the eastern and western coasts of India.
- Thorium: Beach sands of Kerala and Tamil Nadu contain a useful mineral monazite which is used for the extraction of thorium and rare-earths.

### SOME SOLVED PROBLEMS

**Problem 1.** What are four most abundant elements in earth's crust? Arrange them in decreasing abundance.

#### Solution:

Oxygen, silicon, aluminium and iron are the most abundant elements in the earth's crust. The abundance order is:

#### O > Si > Al > Fe

**Problem 2.** In general which metal do you expect to occur in the native state in nature? Give examples.

#### Solution:

The metals which are below hydrogen in the electrochemical series, *i.e.*, which are less electropositive metals can occur in native state in nature. These metals are not readily attacked by oxygen, moisture, carbon dioxide, etc. Examples are: Ag, Au, Pt, Pd, etc. **Problem 3.** Why do metal sulphides occur mainly in rocks and metal halides in lakes and seas?

#### Solution:

Metal sulphides are insoluble in water while metal chlorides are soluble in water. Thus, chlorides get dissolved in rain water and washed away to lakes and seas.

**Problem 4.** What is the role of depressant in froth floatation process?

#### Solution:

The depressants help in the separation of two sulphide ores. For example, in case of an ore containing PbS (Galena) and ZnS (Zinc blende), the depressant is NaCN. It prevents ZnS from coming to the froth but allows PbS to come with froth in the froth floatation process. ZnS forms a soluble complex with NaCN.

$$ZnS + 4NaCN \longrightarrow Na_2Zn(CN)_4 + Na_2S$$
  
Sodium tetracyanozincate (II)

**Problem 5.** What is the significance of leaching in the extraction of aluminium?

#### Solution:

The bauxite ore is always associated with silica, iron oxide and titanium oxide as impurities. These impurities are removed by the process of leaching. The powdered bauxite ore is heated with 45% solution of NaOH at 473–523 K. Alumina and silica dissolve while Fe<sub>2</sub>O<sub>3</sub> and TiO<sub>2</sub> remain insoluble. These are filtered off and solution is neutralised with CO<sub>2</sub> and freshly precipitated Al(OH)<sub>3</sub> is added when hydrated alumina separates out. The sodium silicate remains in solution. Hydrated alumina is separated and dried. This gives pure alumina on heating strongly.

$$\begin{array}{c} \text{Al}_2\text{O}_3 \cdot 2\text{H}_2\text{O} + 2\text{NaOH} + \text{H}_2\text{O} \xrightarrow{473-523 \text{ K}} 2\text{Na[Al(OH)}_4] \\ \text{Bauxite} & \text{Sod. aluminate} \\ \text{SiO}_2 + 2\text{NaOH} \longrightarrow \text{Na}_2\text{SiO}_3 \\ \text{Sod. silicate} \\ 2\text{Na[Al(OH)}_4] + 2\text{CO}_2 \longrightarrow \text{Al}_2\text{O}_3 \cdot 2\text{H}_2\text{O} + 2\text{NaHCO}_3 + \text{H}_2\text{O} \\ \text{Al}_2\text{O}_3 \cdot 2\text{H}_2\text{O} \xrightarrow{1473 \text{ K}} \text{Al}_2\text{O}_3 + 2\text{H}_2\text{O} \end{array}$$

**Problem 6.** Which of the ores can be concentrated by magnetic separation?

#### Solution:

The ores in which one of the components either the actual ore or the impurity is magnetic in nature can be concentrated by magnetic separation. For example, ores of iron such as haematite, magnetite, siderite, etc., can be concentrated by magnetic separation.

**Problem 7.** Differentiate between

- (i) Minerals and ores
- (ii) Roasting and calcination.

#### **Solution:**

(i) The natural substances in which metals occur in the earth are called **minerals**. The mineral has a definite composition. It may be a single compound or a complex mixture. It is usually associated with a number of impurities.

The minerals from which the metals can be conveniently and economically extracted are known as **ores**.

Thus, all ores are minerals but all minerals are not ores.

For example, iron is found in the nature as oxides, carbonate and sulphides. Out of these minerals, the oxides of iron such as haematite, magnetite, etc., are used for extraction. Therefore, oxides of iron are the ores of iron.

- (ii) Calcination is a process in which the ore is heated below its fusion temperature in absence of air. The process does the following things:
  - (a) It removes the volatile impurities like CO<sub>2</sub>, SO<sub>2</sub> organic matter, moisture from the ore.
  - (b) It removes water from hydrated oxide ore.

$$Al_2O_3 \cdot 2H_2O \longrightarrow Al_2O_3 + 2H_2O$$
  
 $2Fe_2O_3 \cdot 3H_2O \longrightarrow 2Fe_2O_3 + 3H_2O$ 

(c) It removes CO<sub>2</sub> from a carbonate ore.

$$CaCO_3 \longrightarrow CaO + CO_2$$

$$CuCO_3$$
·  $Cu(OH)_2 \longrightarrow 2CuO + CO_2 + H_2O$ 

This process is generally done in a reverberatory furnace. This process makes the ore porous.

Roasting is a process in which the ore (usually the sulphide ore) is heated strongly in the presence of excess of air. The heating should be done at a temperature below the melting point of the ore. The ore is heated alone or mixed with some other materials. The process does the following things.

- (a) It dries the ore.
- (b) The volatile impurities like CO<sub>2</sub>, SO<sub>2</sub> organic matter, moisture are all driven out.
- (c) The ore is converted into oxide.

$$2ZnS + 3O_2 \longrightarrow 2ZnO + 2SO_2$$
  
 $2HgS + 3O_2 \longrightarrow 2HgO + 2SO_2$ 

Sometimes sulphide ore is converted into sulphate.

$$PbS + 2O_2 \longrightarrow PbSO_4$$

(d) The sulphide ore is converted into chloride.

$$Ag_2S + 2NaCl \longrightarrow 2AgCl + Na_2S$$

**Problem 8.** Why is the reduction of a metal oxide easier if the metal formed is in liquid state at the temperature of reduction?

#### Solution:

The entropy of a substance is higher in liquid state than in solid state. In the reduction of a metal oxide, the entropy change ( $\Delta S$ ) will be +ve if the metal formed is in liquid state. Thus, the value of  $\Delta G^{\circ}$  becomes negative and reduction occurs easily.

**Problem 9.** Out of C and CO which is a better reducing agent at 673K?

#### Solution:

When carbon acts as a reducing agent, it is either converted into CO or  $CO_2$  or both.

$$2C + O_2 \longrightarrow 2CO$$
$$C + O_2 \longrightarrow CO_2$$

CO is oxidised to CO<sub>2</sub> when it is used as a reducing agent.

$$2CO + O_2 \longrightarrow 2CO_2$$

From the Ellingham diagram, it is clear that at the temperature 673 K, the  $\Delta G^{\circ}$  of the formation of  $CO_2$  from CO is more negative than the formation of CO or  $CO_2$  from carbon. Hence, at temperature 673 K, CO is a better reducing agent than C.

**Problem 10.** Out of C and CO, which is a better reducing agent for ZnO?

#### Solution:

From the Ellingham diagram, it is clear that the free energy of formation of CO from C is lower at temperatures above 1120 K while that of CO<sub>2</sub> from carbon is lower above

1323 K than free energy of formation of ZnO. However, the free energy of formation of CO<sub>2</sub> from CO is always higher than that of ZnO. Hence, C is a better reducing agent of ZnO.

**Problem 11.** The choice of a reducing agent in a particular case depends on thermodynamic factor. How far do you agree with this statement? Support your opinion with two examples.

#### Solution:

From the Ellingham diagram, it is evident that any metal oxide with lower  $\Delta G^{\circ}$  is more stable than the metal oxide with higher  $\Delta G^{\circ}$ . This implies that the metal oxide placed lower in the diagram cannot be reduced by the metal involved in the formation of the oxide placed higher in the diagram. However, reverse can readily take place. Thus,  $Al_2O_3$  cannot be reduced by Cr. However, chromium oxide can be reduced by Al.

At temperature 1773 K, the change in free energy for the formation of Al<sub>2</sub>O<sub>3</sub> and Cr<sub>2</sub>O<sub>3</sub> is given below:

$$2Al + \frac{3}{2}Q_2 \longrightarrow Al_2O_3$$
;  $\Delta G = -900 \text{ kJ mol}^{-1}$  ... (i)  
 $2Cr + \frac{3}{2}Q_2 \longrightarrow Cr_2O_3$ ;  $\Delta G = -500 \text{ kJ mol}^{-1}$  ... (ii)

The reaction for the reduction of Al<sub>2</sub>O<sub>3</sub> with Cr may be obtained by subtracting eq. (i) from eq. (ii).

$$Al_2O_3 + 2Cr \longrightarrow Cr_2O_3 + 2Al; \quad \Delta G = 400 \text{ kJ mol}^{-1}$$

This reaction is thermodynamically not feasible since  $\Delta G$  has +ve value.

The reaction for the reduction of Cr<sub>2</sub>O<sub>3</sub> with Al may be obtained by subtracting eq. (ii) from eq. (i).

$$Cr_2O_3 + 2Al \longrightarrow Al_2O_3 + 2Cr; \quad \Delta G = -400 \text{ kJ mol}^{-1}$$

This reaction is feasible since  $\Delta G$  has negative value. Similarly, both Al and Zn can reduce FeO to Fe but Fe cannot reduce Al<sub>2</sub>O<sub>3</sub> or ZnO.

Thus, thermodynamic factor helps in choosing a suitable reducing agent for the reduction of a particular metal oxide.

**Problem 12.** (i) Suggest a condition under which magnesium could reduce alumina.

(ii) Predict condition under which Al might be expected to reduce MgO.

#### Solution:

- (i)  $\Delta G$  of formation of Al<sub>2</sub>O<sub>3</sub> at temperatures below 1665 K is less negative than  $\Delta G$  of formation of MgO. Thus, below 1665 K magnesium can reduce Al<sub>2</sub>O<sub>3</sub> to Al.
- (ii) The temperature of intersection of the Al  $\longrightarrow$  Al<sub>2</sub>O<sub>3</sub> and Mg  $\longrightarrow$  MgO curves in the Ellingham diagram is 1665 K. Above this temperature,  $\Delta G$  of formation of Al<sub>2</sub>O<sub>3</sub> is more negative than  $\Delta G$  of formation of MgO. Thus, above 1665 K aluminium can reduce MgO into Mg.

**Problem 13.** Copper can be extracted by hydrometallurgy but not zinc. Explain.

#### Solution:

Copper is comparatively less active metal as its reduction potential, *i.e.*,  $E^{\circ}(Cu^{2+}/Cu)$  is high (+ 0.34 V). It can be displaced from solutions of  $Cu^{2+}$  ions by more active metals which have  $E^{\circ}$  values lower than copper. For example,  $E^{\circ}$  of zinc  $(Zn^{2+}/Zn)$  is -0.76 V and thus, zinc can displace copper from solutions of  $Cu^{2+}$  ions.

In contrast to displace zinc from solutions of  $Zn^{2+}$  ions a more reactive metal than it is required. But, the more active metals readily react with water forming their corresponding ions and evolve hydrogen gas. Thus, it is difficult to displace zinc from solutions of  $Zn^{2+}$  ions. Hence, copper can be extracted by hydrometallurgy but not zinc.

# SUMMARY AND IMPORTANT POINTS TO REMEMBER

- The most abundant element in the earth's crust is oxygen. Next to oxygen is the element silicon.
- 2. The most abundant metal in the earth's crust is aluminium.
- The most abundant transition metal in the earth's crust is iron.
- 4. About 88 elements are naturally occurring while the remaining have been synthesized. The earth's crust is the biggest source of metals. Metals occur in nature sometimes free (native state) but mostly in the combined state. The natural substances in which the metals or their compounds occur in the earth are called minerals. The minerals from which the metal can be conveniently and economically extracted are called ores. Ores may be divided into four groups:
  - (a) Native ores: Metals present in free state associated with rock or alluvial materials such as gold, platinum, silver, etc. Sometimes lumps of pure metals are found. These are termed nuggets.

- (b) Sulphurised or arsenical ores: The examples are: Galena (PbS); Zinc blende (ZnS); Cinnabar (HgS); Argentite (Ag<sub>2</sub>S); Copper pyrite (CuFeS<sub>2</sub>); Kupfer nickel (NiAs).
- (c) Oxidised ores: Metals are present as oxides or oxysalts. The examples are: Haematite (Fe<sub>2</sub>O<sub>3</sub>); Bauxite (Al<sub>2</sub>O<sub>3</sub>·2H<sub>2</sub>O); Tinstone (SnO<sub>2</sub>); Rutile (TiO<sub>2</sub>); Zincite (ZnO); Limestone (CaCO<sub>3</sub>); Dolomite (CaCO<sub>3</sub>· MgCO<sub>3</sub>); Malachite [CuCO<sub>3</sub>· Cu(OH)<sub>2</sub>]; Calamine (ZnCO<sub>3</sub>); Chile saltpetre (NaNO<sub>3</sub>); Gypsum (CaSO<sub>4</sub>· 2H<sub>2</sub>O); Barytes (BaSO<sub>4</sub>); Beryl (3BeO· Al<sub>2</sub>O<sub>3</sub>· 6SiO<sub>2</sub>).
- (d) Halide ores : Examples are : Common salt (NaCl); Carnallite (KCl·MgCl $_2$ ·6H $_2$ O), Fluorspar (CaF $_2$ ).
- 5. The whole process of obtaining a pure metal from one of its ores is known as metallurgy. Metallurgy of a metal involves three main operations:
  - (a) Concentration or dressing of the ore (b) Isolation of crude metals (c) Purification or refining.

- 6. The undesired impurities such as sand, clay, rocks, etc., associated with the ore are called gangue or matrix. The removal of these impurities from the ores is known as concentration or dressing of ores. The concentration is done in a number of ways depending upon the nature of impurities.
  - (a) The process of removing the lighter particles of sand, clay, etc., by washing with water either using Wilfley table or Hydraulic classifier is called levigation or gravity separation.
    - The oxide ores of iron (haematite) and tin (cassiterite or tinstone) and native ores of Ag, Au, etc., are concentrated by this process.
  - (b) Electromagnetic separation method is applied when either the ore or the impurities are magnetic in nature. Chromite ore (magnetic) is separated from non-magnetic silicious impurities. Wolframite (FeWO<sub>4</sub>), a magnetic ore is separated from non-magnetic ore, cassiterite (SnO<sub>2</sub>), by this method.
  - (c) Froth floatation process is used for the concentration of sulphide ores. This process is based on the preferential wetting of ore particles by oil (pine oil) and gangue particles by water. Zinc blende, copper pyrites, galena, etc., are concentrated by this process.
  - (d) Leaching involves the treatment of the ore with a suitable reagent to make it soluble while impurities remain insoluble. The ore or the metal is recovered from the solution by a suitable chemical method.
    - For example, bauxite is digested with aqueous solution of NaOH, when  $Al_2O_3$  dissolves forming sodium meta aluminate (NaAlO<sub>2</sub>) while impurities such as  $Fe_2O_3$ ,  $TiO_2$  and silica remain insoluble. Pure alumina is recovered from the filtrate.
    - Native ores of Ag and Au are treated with aqueous dilute solution of NaCN in presence of oxygen. The Ag and Au particles get dissolved forming complex cyanides. Ag or Au is recovered from the solution by addition of electropositive metal, Zn.
- 7. Extraction of crude metals: Metals are usually extracted by reduction. Thus, the concentrated ore is converted into a form which is suitable for reduction. Oxides are easier to reduce. Therefore, the extraction involves the following two steps:
  - (a) Conversion of the ore into metallic oxide.
  - (b) Reduction of metallic oxide.
  - (a) Two methods are used for conversion into oxides.
    - (i) Calcination involves heating of the ore below its fusion temperature in absence of air. This step expels organic matter and moisture from the ores. Carbonates may be decomposed.
    - (ii) Roasting involves heating of the ore either alone or with some other material in presence of oxygen (air) below its fusion temperature. This process is generally done in a reverberatory furnace. Nonmetallic impurities are removed as their volatile oxides. The ores such as sulphides are simultaneously converted into corresponding oxides either partially or completely.
  - (b) Reduction of the oxide to the free metal is done by a suitable reducing agent. The following methods can be applied.

- (i) Smelting: The process of extracting a metal by heating the metal oxide with a suitable reducing agent such as C, H<sub>2</sub>, CO, water gas, Na, K, Mg, Al, etc., at high temperature is called smelting. The process, in general, is termed pyrometallurgy. It is applicable especially for the extraction of less electropositive metals such as Fe, Zn, Pb, Sn, etc., carbon, carbon monoxide and aluminium are generally used as reducing agents.
  - The term smelting is applied when coke or carbon is used as a reducing agent. The ore is mixed with a suitable quantity of coke or charcoal (acts as a reducing agent) and heated to a high temperature above its melting point. An additional reagent is usually added to the concentrated ore to remove if still impurities are present. This additional reagent is called flux. Flux combines with impurities and forms a fusible slag. The selection of flux depends on the nature of impurities. If impurities are acidic, basic flux such as CaO is used while acidic flux such as silica is used if the impurities are basic. The process is carried out in a blast furnace.
- (ii) Goldschmidt aluminothermic process—Reduction by aluminium: This process is used in the case of those metals which have very high melting points and are to be extracted from their oxides. A mixture of metal oxide and aluminium powder, commonly called as thermite, is taken in a steel crucible placed in a bed of sand. The reaction is started by the use of an ignition mixture containing magnesium powder and barium peroxide.
- (iii) Auto or Self reduction process: The sulphide ores of less electropositive metals like Hg, Pb, Cu, etc., are heated in air as to convert part of the ore into oxide or sulphate which then reacts with the remaining sulphide ore to give the metal and SO<sub>2</sub>. No external reducing agent is used in this process.
- (iv) Electrolytic reduction: The highly electropositive metals such as alkali metals, alkaline earth metals, Al, etc., are extracted by the electrolysis of hydroxides, chlorides or oxides in the fused state. Sometimes, a small amount of some other salt is added to decreases the fusion temperature or to increase the conductivity or both. The metal is liberated at the cathode.
- (v) Hydrometallurgy: Certain metals such as silver and gold are extracted by dissolving the concentrated ore in some suitable reagent and then recovering the metal from the solution by treatment with some more electropositive metal.
- 8. Thermodynamic principles: The basic concepts of thermodynamics are quite helpful in selecting a suitable reducing agent for a particular oxide. In the oxidation reduction reaction, the Gibbs free energy change should be negative at an appropriate temperature.

$$\Delta G^{\circ} = \Delta H^{\circ} - T \Delta S^{\circ}$$

The concept is graphically displayed in plots of  $\Delta G^{\circ}$  vs T (Ellingham diagram). Any metal oxide with lower value of  $\Delta G^{\circ}$  is more stable than metal oxide with higher  $\Delta G^{\circ}$ . This implies that metal oxide placed higher in the diagram can

be reduced by the metal involved in the formation of the oxide placed lower in the diagram. This concept is applied in the extraction of Fe, Zn and Cu.

9. The concept of electrode potential is useful in the isolation of the metals either by electrolysis or by displacing one metal by other in the solution. The sum of the E° of two redox couples should be positive so that Gibbs energy change is negative.

$$\Delta G^{\circ} = -nFE^{\circ}$$

The process of extraction of metals by electrolysis of their fused salts is called electrometallurgy. In electrolysis, electrons act as reducing agent at cathode. One example of the electrometallurgy is the extraction of aluminium metal from bauxite ore.

- Third operation: Purification or refining: The process of purifying impure metals is called refining.
  - (a) Liquation process: The process is based on the difference in fusibility of the metal and impurities. When the impurities are less fusible than the metal itself, this process is used. The impure metal such as Bi, Sn, Pb, Hg, etc., is placed on the sloping hearth of a furnace and gently heated. The metal melts and flows down.
  - (b) Distillation: The process is used for those metals which are volatile. The impure metal is heated and the vapours are separately condensed in a receiver. This is used for the purification of Zn, Cd, Hg, etc.
  - (c) Cupellation: The impure metal is heated in cupel or oval shaped crucible made of bone ash or cement and a blast of air is passed over the molten mass. The impurities are oxidised and removed with the blast of air. Impurity of lead in silver is removed by this process.
  - (d) Poling: It is used for purification of those metals which contain their own oxides as impurity. The molten impure metal is stirred with green poles of wood.
  - (e) Electrorefining: Metals like Cu, Ag, Au, Ni, Cr, Al, etc., are purified by this method. The impure metal is made the anode and a strip of pure metal is made as cathode while electrolytic solution consists of a solution of a suitable salt of the metal.
  - (f) Zone refining: When highly pure metals are required, this method is applied for purification. The method is based on the difference in solubility of impurities in molten and solid state of the metal. This method is used in purification of germanium, gallium, silicon, etc., which are used as semiconductors.
  - (g) Van Arkel process: This method is used for obtaining ultrapure metals. The impure metal is converted into volatile compound which is then decomposed electrically to get pure metal. Ti, Zr, Hf, Si, etc., are refined by this method.

$$\begin{array}{ccc} \text{Impure} & + \text{ } I_2 \rightarrow \text{Metal iodide} & \xrightarrow[\text{flament}]{\text{Heating}} & \text{Metal} & + \text{ } I_2 \\ \text{metal} & & & \text{vapours} & & \text{flament} \end{array}$$

**(h) Mond's process:** Nickel is purified by this method. The impure nickel is treated with CO at 330–350 K, when

volatile nickel carbonyl is formed. The carbonyl is subjected to 450-470 K, when it decomposes giving pure nickel.

Impure + CO 
$$\xrightarrow{330-350 \text{ K}}$$
 NiCO<sub>4</sub>  $\xrightarrow{450-470 \text{ K}}$  Ni + 4CO nickel  $\xrightarrow{\text{Volatile}}$  compound

- (i) Chromatographic methods: It is based on selective distribution of various constituents of a mixture between two phases, a stationary phase and a moving phase. The stationary phase can be either solid or tightly bound liquid on a solid support. The moving phase may be a liquid or a gas. Different types of chromatographic methods have been developed. The most common are:
  - (a) Column chromatography,
  - (b) Thin layer chromatography,
  - (c) Paper chromatography,
  - (d) Gas chromatography, etc.

Column chromatography is the simplest method. This is based on adsorption phenomenon. The extent of adsorption of various constituents present in the mixture liquid (moving phase) varies with a given adsorbent (stationary phase). The common adsorbents used are alumina, silica gel, magnesium oxide, active animal charcoal, etc.

It involves the following steps:

- (a) Preparation of adsorption column
- (b) Adsorption
- (c) Elution of components and recovery.

This method is useful for those elements which are available in small amounts and the impurities are not much different in chemical properties from the element to be purified.

- 11. The materials which can withstand very high temperatures without melting or becoming soft are known as refractory materials. These are used in the form of bricks for the internal linings of furnaces. Silica, quartz, lime, graphite, bone ash, etc., are used as refractory materials. Refractory materials are of three types:
  - (i) Acid refractories: Silica, quartz, silicious sand stones, etc., are the examples.
  - (ii) Basic refractories: Lime, dolomite, magnesite, etc., are the examples.
  - (iii) Natural refractories: Graphite, chromite, bone ash, etc., are the examples.

Silica (92% SiO<sub>2</sub>, 2.7% Al<sub>2</sub>O<sub>3</sub>) and quartz can tolerate temperatures upto about 1750°C, bauxite upto 1800°C, alumina upto 2000°C and magnesite, chromite, etc., upto 2200°C. Some carbides such as silicon carbide is used as refractory for special purposes.

12. India has abundant reserves of coal, mica ore, manganese ore, iron ore, aluminium ore, titanium ore, etc., but particularly poor in non-ferrous metals.

## -•••- PRACTICE PROBLEMS -•••-

#### **■** Subjective Type Questions

- 1. (a) Name one oxide ore of each of the following metals :
  - (i) iron (ii) zinc (iii) aluminium
  - (b) Name the metal present in :
    - (i) chlorophyll (ii) haemoglobin
- 2. (a) What types of ores are roasted?
  - (b) How is copper pyrite concentrated?
  - (c) How is bauxite generally concentrated?
- (a) Name the diagram which can be used to compare the reducing nature of different elements.
  - (b) Indicate the temperature at which carbon can be used as reducing agent for FeO.
  - (c) Which is a better reducing agent below 983 K, Carbon or carbon monoxide?

#### 4. Name the following:

- (i) Two metals which never occur in native state.
- (ii) Two metals which always occur both in native and in combined states.
- (iii) Two metals which always occur naturally in an uncombined state.
- (iv) Two metals which are manufactured by the electrolysis of their fused salts.
- (v) Two metals which are used for the reduction in metallurgical process.
- **5.** Name the metals with which the following ores/minerals are associated :
  - (i) Cryolite
- (ii) Dolomite (iii) Calamine
- (iv) Haematite
- (v) Malachite (vi) Lepidolite
- (vii) Polyhalide (viii) Triphylite (ix) Borax (x) Chromite
- 6. What term is assigned to the following?
  - (i) Naturally occurring compounds from which metals are extracted profitably.
  - (ii) Sulphide ores are generally heated in a stream of air.
  - (iii) Metal is extracted from its ore by heating the ore with a suitable reducing agent.
  - (iv) Metal ions get discharged on an electrode.
  - (v) The materials which can withstand very high temperatures without melting and softening.
  - (vi) The substances used for the removal of gangue in the ores in the form of slags.
  - (vii) The process in which aluminium is used as a reducing agent for the extraction of metal from its oxide.
- 7. Differentiate the following giving a suitable example :
  - (i) Mineral and ore
  - (ii) Calcination and roasting
  - (iii) Flux and slag
  - (iv) Smelting and roasting-
- 8. Write short notes on:
  - (i) Froth floatation process (ii) Calcination
  - (iii) Roasting
- (iv) Smelting
- (v) Hydrometallurgy
- (vi) Pyrometallurgy

- (vii) Autoreduction
- (viii) Electrolytic refining
- (ix) Reverberatory furnace
- (x) Blast furnace
- (xi) Leaching
- (xii) Cupellation
- 9. (a) Which of the following metals can be obtained by the electrolytic reduction of aqueous solution of their salts— Al, Na, Cu and Ag?
  - (b) Which of the metals Na, Ag and Fe are extracted by,
    - (i) Complex formation
    - (ii) Reduction with carbon and
    - (iii) Electrolysis of fused salt?
  - (c) Which ores are generally concentrated by froth floatation process?
  - (d) (i) Which of the following metals is lightest and which one of them is least reactive?

(ii) Which one out of the two may be found in native state?

#### 10. Explain the following:

(i) Zinc but not copper is used for the recovery of Ag from the complex [Ag(CN)<sub>2</sub>]<sup>-</sup>.

[Hint: Zinc is more powerful reducing agent in comparison to copper. Zinc is also cheaper than copper.]

(ii) Partial roasting of sulphide ore is done in the metallurgy of copper.

[Hint: Partial roasting of sulphide ore forms some oxide.

This oxide then reduces the remaining sulphide ore into metal.

$$2CuS + 3O_2 \longrightarrow 2CuO + 2SO_2$$

$$2CuO + CuS \longrightarrow 3Cu + SO_2$$
 (Autoreduction) ]

(iii) Why is chalcocite roasted and not calcined during recovery of copper?

[Hint: Chalcocite is a sulphide ore. It is to be converted into oxide and thus roasting and not calcination is done.]

(iv) Aluminium metal is frequently used as a reducing agent for the extraction of metals such as chromium, manganese, etc.

[Hint: Aluminium has great affinity for oxygen. It acts as a reducing agent when the metal having high melting point is to be extracted from its oxide.

$$Cr_2O_3 + 2Al \longrightarrow 2Cr + Al_2O_3$$

(v) Magnesium oxide is used for the lining in steel making furnace.

[Hint: Magnesium oxide acts as a flux to remove impurities of Si, P and S through slag formation.

$$\begin{array}{c} MgO + SiO_2 \longrightarrow MgSiO_3 \\ 3MgO + P_2O_5 \longrightarrow Mg_3(PO_4)_2 \\ MgO + SO_2 \longrightarrow MgSO_3 \end{array} \end{array} \} Slag I$$

- 11. How the following impurities can be removed?
  - (a) An impurity of lead in silver.
  - (b) An impurity of cuprous oxide in copper.
  - (c) Impurities of Fe, Cu, etc., in aluminium.
- **12.** Describe the thermodynamic principles of metallurgy. How Ellingham diagram is useful in predicting the feasibility of thermal reduction of a metal oxide.
- 13. Describe the principle of extraction of each of the following:(a) Cu from CuFeS<sub>2</sub> (b) Zn from ZnO (c) Fe from Fe<sub>2</sub>O<sub>3</sub>
- 14. Explain the following:
  - (a) Carbon reduction process is not applied for reducing alumina.
  - (b) Aqueous solution of sodium chloride cannot be used for the isolation of sodium by electrolysis.
  - (c) Graphite is used as anode and not diamond.

#### ■ Matching Type Questions

#### Match the following:

[A] (a) Al	(i)	Cinnabar
(b) Cu	(ii)	Calamine
(c) Mg	(iii)	Cryolite
(d) Zn	(iv)	Malachite
(e) Hg	(v)	Carnallite

[B]	(a) Zn	(i) Self reduction
	(b) Ag	(ii) Fused salt electrolysis
	(c) Fe	(iii) Carbon reduction
	(d) Ca	(iv) Amalgamation
	(e) Cu	(v) CO reduction

(i) PbS
(ii) KCl·MgCl <sub>2</sub> ·6H <sub>2</sub> O
(iii) Al <sub>2</sub> O <sub>3</sub> ·2H <sub>2</sub> O
(iv) SnO <sub>2</sub>
(v) ZnCO <sub>3</sub>
(i) Silver
(iii) Al <sub>2</sub> O <sub>3</sub> ·2H <sub>2</sub> O (iv) SnO <sub>2</sub> (v) ZnCO <sub>3</sub>

(b) Mona's process	(11) Iron
(c) Cupellation	(iii) Carbonate ores
(d) Calcination	(iv) Froth floatation proces
(e) Pyrometallurgy	(v) Nickel

### Answers

#### Answers: Subjective Type Questions

- 1. (a) (i) Haematite (ii) Zincite (iii) Bauxite
  - (b) (i) Magnesium (ii) Iron
- 2. (a) sulphide ores (b) froth floatation process (c) leaching
- 3. (a) Ellingham diagram (b) Above 1123 K (c) Carbon monoxide
- (i) Sodium and potassium; (ii) Copper, silver; (iii) Au, Pt; (iv) Sodium, aluminium; (v) Aluminium, magnesium, iron or sodium.
- 5. (i) Na and Al; (ii) Mg and Ca; (iii) Zn; (iv) Fe; (v) Cu; (vi) Li, Al, Na and K; (vii) K, Mg and Ca; (viii) Li, Na, Fe and Mn; (ix) Na; (x) Cr, Fe.
- (i) ores, (ii) roasting, (iii) smelting, (iv) electrolytic reduction,
   (v) refractory materials, (vi) fluxes, (vii) thermite process.
- (a) Cu and Ag; (b) (i) Ag, (ii) Fe, (iii) Na; (c) Sulphide ores; (d) (i) lightest element Al, least reactive Ag, (ii) Ag.
- 11. (a) Cupellation, (b) Poling, (c) Electrolytic.

#### Answers: Matching Type Questions

(A) (a—iii); (b—iv); (c—v); (d—ii); (e—i) (B) (a—iii); (b—iv); (c—v); (d—ii); (e—i) (C) (a—v); (b—i); (c—iv); (d—iii); (e—ii) (D) (a—iv); (b—v); (c—i); (d—iii); (e—ii)

### ILLUSTRATIONS OF OBJECTIVE QUESTIONS

1. The main ore of lead is galena (PbS). Lead is extracted from galena ore either by (A) or (B).

(A) PbS 
$$\xrightarrow{\text{Roasted}}$$
 PbO + SO<sub>2</sub>

Heated with C  $\rightarrow$  Pb + CO<sub>2</sub>

(B) PbS  $\xrightarrow{\text{Roasted}}$  PbO + PbS

(B) PbS 
$$\xrightarrow{\text{Roasted}}$$
 PbO + PbS

Heated with PbS Pb + SO<sub>2</sub>

Auto-reduction process is:

- (b) B (a) A
- (c) both
- (d) none

Which of the following processes involves smelting?

(a) 
$$ZnCO_3 \xrightarrow{Heat} ZnO + CO_2$$

(b) 
$$2PbS + 3O_2 \xrightarrow{\text{Heat}} 2PbO + 2SO_2$$

(c) 
$$Al_2O_3 \cdot 2H_2O \xrightarrow{Heat} Al_2O_3 + 2H_2O$$

(d) 
$$Fe_2O_3 + 3C \xrightarrow{Heat} 2Fe + 3CO$$

Ans. (d)

- Consider the following statements:
  - Roasting is carried out to:
  - 1. convert sulphide into oxide
  - 2. melt the ore
  - 3. remove moisture, water of hydration and expel organic
  - 4. remove sulphur and arsenic in the form of volatile oxides

Out of these statements:

- (a) 1, 3 and 4 are correct
- (b) 1, 2 and 3 are correct
- (c) 2, 3 and 4 are correct
- (d) 1, 2 and 4 are correct

Ans. (a)

4. Match List I with List II and select the correct answer using the codes given ahead:

#### List I

- A. Mond's process 1. Purification of copper
- B. Van Arkel method
- C. Cupellation
- D. Distillation

#### Codes:

- (a) A-1, B-2, C-3, D-4
- (c) A-3, B-4, C-1, D-2
- (b) A-2, B-3, C-4, D-1

Purification of zinc

Purification of nickel

Purification of titanium

(d) A-4, B-1, C-2, D-3

List II

Ans : (c)

Match List I with List II and select the correct answer using the codes given below:

List I

- A. Cinnabar
  - 1. Zinc
- B. Cassiterite
- 2. Aluminium

List II

- C. Bauxite
- 3. Tin Mercury

D. Calamine Codes:

- (a) A 4, B 3, C 2, D 1(b) A - 1, B - 2, C - 3, D - 4
- (c) A 2, B 3, C 4, D 1
- (d) A 3, B 4, C 1, D 2

Ans : (a)

- The method of zone refining of metals is based on the principle of:
  - (a) greater mobility of the pure metal than that of impurity
  - (b) greater solubility of the impurity in the molten state than in the solid
  - (c) higher melting point of the impurity than that of the pure metal
  - (d) all above are correct

In the equation,  $4M + 8CN^- + 2H_2O + O_2 \longrightarrow$ 

 $4[M(CN)_2] + 4OH$ , the metal M is:

- (a) copper
- (b) iron

(c) gold

(d) zinc

Ans : (c)

### **OBJECTIVE QUESTIONS**

Set I: This set contains questions with one correct answer.

1.	The most abundant metal in the earth crust is:	12.	Autoreduction process is used in the extraction of:		
	[J.E.E. (W.B.) 20	10]		(a) Cu and Hg	
	(a) Al			(c) Cu and Al	
	(c) Ca		13.	In thermite process, the reducing agent is:	
2.	Which metal is generally found in native state?			(a) C	
	(a) Cu			(c) Na	
	(c) Al		14.	Complex formation method is used for the extraction of	f:
3.	A mineral is called ore if:			(a) Zn	
	(a) the metal present in the mineral is costly			(c) Hg	
	(b) a metal can be extracted from it		15.	Carbon monoxide reduction process is used for t	the
	(c) a metal can be extracted profitably from it			extraction of :	
	(d) a metal cannot be extracted from it			(a) Cu	
4.	Select the correct statement.			(c) Fe	
	(a) Dolomite is the ore of zinc		16.	Gold is extracted by hydrometallurgical process based	
	(b) Galena is the ore of mercury			its property: [C.E.T. (Karnataka) 200	05]
	(c) Pyrolusite is the ore of iron			(a) of being electropositive	. 🗆
	(d) Cassiterite is the ore of tin			(b) to form complexes which are water soluble	
5.	Which of the following pairs consists of minerals of	the		(c) of being less reactive	
	same metal?		107	(d) to form salts which are water soluble	
	(a) Bauxite, Limonite   (b) Haematite, Magnetite		17.	Argentite is a mineral of:	
	(c) Galena, Cerusite			(a) Au	
6.	Froth floatation process is based on: [P.E.T. (Kerala) 20	05]	10	(c) Ag	
	(a) specific gravity of the ore particles		10.	employed to extract:	15
	(b) magnetic properties of the ore particles			(a) lead	
	(c) wetting properties of the ore particles			(c) sodium	
	(d) electrical properties of the ore particles		10	When ZnS and PbS minerals are present together, NaCN	
7.	The function of flux during the smelting of the ore is:		17.	added to separate them in froth floatation process becau	
	(a) to make the ore porous			(a) Pb(CN) <sub>2</sub> is precipitated while there is no effect on Z	
	(b) to remove gangue			(A) 1 2 (G-3)/2 to prostprimote while the to the chief of the	
	(c) to facilitate reduction			(b) ZnS forms soluble complex, Na <sub>2</sub> Zn(CN) <sub>4</sub>	
	(d) to facilitate oxidation			(c) PbS forms soluble complex, Na <sub>2</sub> Pb(CN) <sub>4</sub>	
8.	Name the metal M which is extracted on the basis	of	-	(d) both (a) and (b)	
	following reactions:			[Hint: $ZnS + 4NaCN \longrightarrow Na_2Zn(CN)_4 + Na_2S$ ]	
	$4M + 8NaCN + 2H_2O + O_2 \longrightarrow 4NaM(CN)_2 + 4NaO_2$	H	20.	2 0.7	the
	$2NaM(CN)_2 + Zn \longrightarrow Na_2Zn(CN)_4 + 2M$			method used is:	
	(a) Au or Ag			(a) carbon reduction	
	(c) Ni			(b) carbon monoxide reduction	
9.	Which of the following statements is true?			(c) aluminothermic	
	(a) All ores are minerals			(d) electrolytic reduction	
	(b) All minerals are ores		21.	Poling process is used:	
	(c) A mineral cannot be an ore			(a) for the removal of Cu <sub>2</sub> O from Cu	
	(d) An ore cannot be a mineral			(b) for the removal of Al <sub>2</sub> O <sub>3</sub> from Al	
10.	The impurities present in the mineral are called:			(c) for the removal of Fe <sub>2</sub> O <sub>3</sub> from Fe	
	[J.E.E. (Orissa) 20	010]		(d) in all the above	
	(a) flux		22.	$ACl_2 + BCl_2 \longrightarrow ACl_4 + B \downarrow$	
	(c) alloy			· (Excess)	
11.	Electrolytic reduction process is used for the extraction	of:		$BO \xrightarrow{\text{Heat}} B + 1/2 O_2$	
	(a) alkali metals			(A and B are metals.)	
	(c) aluminium		1	The ore of $B$ is :	

	(a) cinnabar (c) galena [ <b>Hint</b> : SnCl <sub>2</sub> + HgCl			36.	The furnace lining in ste (i) CaO (ii) SiO <sub>2</sub> (iii) I (a) (ii) and (iv)	el manufacture consists of :  MgO (iv) CaCO <sub>3</sub> (b) (i) and (iii)	
	HgC	$\longrightarrow$ Hg + 1/2 O <sub>2</sub> ]	ł		(c) (iii) and (iv)	☐ (d) (ii), (iii) and (iv)	
23.	Essential constituent of a	imalgam is :	Ì	37.	The furnace which gives	the highest temperature is:	:
	(a) an alkali metal	□ (b) silver			(a) blast furnace	(b) reverberatory furn	ace 🗆
	(c) mercury	☐ (d) iron			(c) electrical furnace	☐ (d) muffle furnace	
24.	Heating of pyrites in pre-	esence of air to remove su	ulphur is	38.	Which method of pur	ification is represented by	y the
	called as:	[A.F.M.	.C. 2005]		following equations?		
	(a) roasting	☐ (b) calcination			•	J.E.E. (Orissa)	2010]
	(c) smelting	(d) fluxing			523 K	1700 K	
25.	Calamine is:	•			$Ti + 2I_2 - \frac{323 \cdot 1}{2}$	$\rightarrow$ TiI <sub>4</sub> $\xrightarrow{1700 \text{ K}}$ Ti + 2I <sub>2</sub>	
	(a) ZnSO <sub>4</sub>	□ (b) ZnO			(a) Cupellation	□ (b) Poling	
	(c). ZnS	$\Box$ (d) ZnCO <sub>3</sub>			(c) Van Arkel	☐ (d) Zone refining	
26.	Radium is obtained from	n :		39.	Van Arkel method of	purification of metals in	volves
	(a) pitchblende	☐ (b) haematite			converting the metal to	——————————————————————————————————————	
	(c) monazite	☐ (d) none of these			(a) volatile stable compe		
27.	From gold amalgam, go	ld may be recovered by :			(b) volatile unstable con	npound	
	(a) addition of Zn metal				(c) non-volatile stable of	ompound	
	(b) electrolytic refining				(d) none of the above	•	
	(c) distillation			40.	Zone refining is a method	od to obtain:	
	(d) dissolving Hg in HN	$NO_3$			(a) very high temperatu		
28.	Froth floatation process				(b) ultrapure Al		
	(a) oxide ores	☐ (b) sulphide ores			(c) ultrapure metals		
	(c) chloride ores	☐ (d) all of these			(d) ultrapure oxides		
29.	Leaching is a process of			41.	MgO can be used as ref	ractory material because:	
	(a) reduction	☐ (b) concentration			(a) it is a good electrica	-	
	(c) refining	☐ (d) oxidation			(b) it has high melting		
30.	Which one of the follow				(c) it is a good conductor	<del>-</del>	
	(a) CaCO <sub>3</sub>	(b) CaO			(d) all of these		
	(c) SiO <sub>2</sub>	☐ (d) MgO		42.		r the extraction of which me	etals ?
31.	Ore dressing for iron is	•			(i) Pb (ii) Al (iii) Ag		
	(a) froth floatation proc				-	☐ (b) (i), (ii) and (iii)	
	(b) magnetic separation				(c) (ii) and (iv)	☐ (d) (iii) and (iv)	
,	(c) hand picking			43.		the one which cannot be ob	tained
	(d) all of the above					ueous solution of its salt is	
32.		iron from haematite, lim	estone is		(a) Ag	□ (b) Mg	
	added to act as:				(c) Cu	□ (d) Al	
	(a) flux	☐ (b) slag		44.		n technique is used in the ext	raction
	(c) a reducing agent	☐ (d) an oxidising age	ent 🗆		of:	1	
33.	Carnallite is a double sa				(a) highly electronegative	ve elements	
	(a) NaCl, NaNO <sub>3</sub>	$\Box$ (b) K <sub>2</sub> O, Al <sub>2</sub> O <sub>3</sub>			(b) transition metals		
	(c) KCl, MgCl <sub>2</sub>	☐ (d) NaCl, MgCl <sub>2</sub>		1	(c) metalloids		
34.	•	reactions occur during cal	lcination?		(d) highly electropositive	ve elements	
	(i) $CaCO_3 \longrightarrow$	_		45.			
	(ii) $4\text{FeS}_2 + 11\text{O}_2 \longrightarrow$				(a) CaO	☐ (b) P <sub>2</sub> O <sub>5</sub>	
	(iii) $2Al(OH)_3 \longrightarrow$				(c) SiO <sub>2</sub>	☐ (d) MgO	
	(iv) $Cu_2S + 2CuO \longrightarrow$			46.	The metal extracted from	S .	
	(a) (i) and (iii)	☐ (b) (i) and (ii)			(a) Mg	□ (b) Al	
	(c) (i) and (iv)	☐ (d) (iii) and (iv)			(c) Ca	□ (d) Ba	
35.			*****	47.		s in which a metal is obtaine	
	(a) to remove the vola				fused state is called:		
	(b) oxidation	1		1	(a) smelting	☐ (b) roasting	
	(c) reduction				(c) calcination	☐ (d) froth floatation	
	(d) to make slag						

	,		
48.	Asbestos is a silicate mineral of calcium and :		(c) I–C, II–B, III–D, IV–A
	(a) Al		(d) I–D, II–A, III–C, IV–B $\Box$
	(c) Ba	58.	Which of the following does not contain Mg?
49.	Which method of purification is represented by the		(a) Magnetite
	following equation?		(c) Asbestos   (d) Carnallite
	$Ni + 4CO \xrightarrow{70^{\circ}C} Ni(CO)_4 \xrightarrow{180^{\circ}C} Ni + 4CO$	59.	$Ag_2S + NaCN \longrightarrow [A]$
	(a) Van Arkel		$[A] + Zn \longrightarrow [B]$
	(c) Mond		[B] is a metal. Hence, [A] and [B] are:
50.	Which oil is used as frother in froth floatation process?		(a) $Na_2[Zn(CN)_4]$ , $Zn \square$ (b) $Na[Ag(CN)_2]$ , $Ag \square$
50.	(a) Mustard oil		(c) $Na_2[Ag(CN)_4]$ , $Ag \square$ (d) $Na_3[Ag(CN)_4]$ , $Ag \square$
	(c) Olive oil	60.	Which of the following metals is leached by cyanide
51.	The incorrect statement is:		process? [A.I.E.E.E. 2002]
J1.	(a) Calamine and siderite are carbonates		(a) Ag
			(c) Al
	(b) Argentite and cuprite are oxides ☐ (c) Zinc blende and iron pyrites are sulphides ☐	61.	Pyrolusite is a/an: [D.P.M.T. 2002]
	(d) Malachite and azurite are ores of copper		(a) oxide ore $\Box$ (b) sulphide ore $\Box$
52			(c) carbide ore $\Box$ (d) not an ore $\Box$
52.	In the commercial electrochemical process for aluminium	62.	Which one of the following ores is not concentrated by froth
	extraction, the electrolyte used is :  (a) Al(OH) <sub>3</sub> in NaOH solution		floatation process? [C.E.T. (Tamil Nadu) 2002]
			(a) Copper pyrites   (b) Pentlandite
	1		(c) Pyrolusite $\Box$ (d) Zinc blende $\Box$
	(c) A molten mixture of Al <sub>2</sub> O <sub>3</sub> and Na <sub>3</sub> AlF <sub>6</sub> ☐ (d) A molten mixture of Al <sub>2</sub> O <sub>3</sub> and Al(OH) <sub>3</sub> ☐	63.	The common method of extraction of metal from oxide ores
52			is: [P.E.T. (M.P.) 2002]
53.			(a) reduction with carbon
	electrolysed using platinum electrodes, the ions discharged at the electrodes are :		(b) reduction with hydrogen
			(c) reduction with aluminium
	, ,		(d) electrolytic method
		64.	Sulphide ores of metals are usually concentrated by froth
	, , , , , , , , , , , , , , , , , , ,		floatation process. Which one of the following sulphide ores
54	(d) hydroxyl and chloride   Cassiterite is an ore of:		offers an exception and is concentrated by chemical
J <del>4</del> .	(a) Mn		leaching? [C.B.S.E. 2007]
	(c) Sb		(a) Galena
55	Cryolite is: [C.P.M.T. 2000]		(c) Sphalerite $\Box$ (d) Argentite $\Box$
55,	(a) Na <sub>3</sub> AlF <sub>6</sub> and is used in the electrolysis of alumina for	65.	Among the metals Cr, Fe, Mn, Ti, Ba and Mg, the one that
	decreasing electrical conductivity		cannot be obtained by reduction of its metal oxide by
	(b) Na <sub>3</sub> AlF <sub>6</sub> and is used in the electrolysis of alumina for		aluminium is: [P.M.T. (Kerala) 2007]
	lowering the melting point of alumina		(a) $Cr$ $\Box$ (b) $Fe$ $\Box$
	(c) Na <sub>3</sub> AlF <sub>6</sub> and is used in the electrolytic purification of	-	(c) Mn
	alumina		(e) Mg □
	(d) Na <sub>3</sub> AlF <sub>6</sub> and is used in the electrolysis of alumina	66.	Native silver metal forms a water soluble complex with a
56.	The process of converting hydrated alumina into anhydrous		dilute aqueous solution of NaCN in the presence of:
50.	alumina is called : [Roorkee (S) 2000]		[I.I.T. 2008]
	(a) roasting $\Box$ (b) smelting $\Box$		(a) nitrogen $\Box$ (b) oxygen $\Box$
	(c) dressing $\Box$ (d) calcination $\Box$		(c) carbon dioxide
57.	Match List I with List II and select the correct answer using		[Hint: $4Ag + 8NaCN + 2H_2O + O_2 \longrightarrow 4[NaAg(CN)_2]$
57.	codes given below in the lists: [S.C.R.A. 2001]		+ 4NaOH]
	List I List II	67.	Which of the following factors is of no significance for
	I. cyanide process A. ultrapure Ge		roasting sulphide ores to the oxides and not subjecting the
	II. floatation process B. pine oil		sulphide ores to carbon reduction directly?[A.I.E.E.E. 2008]
	III. electrolytic reduction C. extraction of Al		(a) $CO_2$ is more volatile than $CS_2$
	IV. zone refining D. extraction of Au		(b) Metal sulphides are thermodynamically more stable
	Codes:		than CS <sub>2</sub>
	(a) I–C, II–A, III–D, IV–B		(c) $CO_2$ is thermodynamically more stable than $CS_2$
	(b) I–D, II–B, III–C, IV–A		(d) Metal sulphides are less stable than the corresponding
	(0) 1 D, 11 D, 11 T, 14 T		oxides □

	[Hint: The reduction process is on the thermodynamic stability		(a) Zinc can be oxidised by CO	
	of the products and not on their volatility.]		(b) Zinc oxide can be reduced by C	
68.	Composition of azurite mineral is: [J.E.E. (W.B.) 2008]	~	(c) Both statements (a) and (b) are true	
	(a) $CuCO_3$ · $CuO$		(d) Both statements (a) and (b) are false	
	(c) $2CuCO_3 \cdot Cu(OH)_2  \Box$ (d) $CuCO_3 \cdot 2Cu(OH)_2  \Box$	74.	The ore that is concentrated by froth floatation process	s is :
69.	Which of the following metal is not manufactured by		[C.E.T. (Karnataka)	2009]
	electrolysis? [P.M.T. (Kerala) 2008]		(a) cinnabar (b) bauxite	
	(a) Na		(c) malachite	
	(c) Al	75.	Hydro-metallurgical process of extraction of metals is l	oased
	(d) Li		on: [J.E.E. (Orissa)	2009]
<i>7</i> 0.	The method not used in metallurgy to refine the impure		(a) complex formation □ (b) hydrolysis	
	metal is: [P.M.T. (Kerala) 2008]		(c) dehydration	
	(a) Mond process $\square$ (b) Van Arkel process $\square$	76.	In alumino-thermic process, aluminium is used as:	
	(c) Amalgamation process		[J.E.E. (Orissa)	2009]
	(d) Liquidation		(a) oxidising agent	
71.	Extraction of zinc from zinc blende is achieved by:	ļ	(b) reducing agent	, $\square$
	[I.I.T. 2007]		(c) dehydrating agent	
	(a) electrolytic reduction		(d) complex formation agent	
	(b) roasting followed by reduction with carbon	<i>7</i> 7.	According to Ellingham diagram, the oxidation reacti	on of
	(c) roasting followed by reduction with another metal $\Box$		carbon and carbon monoxide may be used to reduce v	vhich
	(d) roasting followed by self reduction $\Box$		one of the following oxides at the lowest temperature	es?
	[Hint: $2ZnS + 3O_2 \longrightarrow 2ZnO + 2SO_2$ ;		[P.E.T. (Kerala)	2010]
	$ZnO + C \xrightarrow{> 1270 \text{ K}} Zn + CO$		(a) $Al_2O_3$	
72.			(c) MgO	
<i>,</i>	the reaction: [K.C.E.T. 2006]	78.	The chemical reaction that involves roasting process	
			[E.A.M.C.E.T. (Engg.)	2010]
	(a) $Mg + \frac{1}{2}O_2 \longrightarrow MgO \square$ (b) $2Ag + \frac{1}{2}O_2 \longrightarrow Ag_2O\square$	:	(a) $Fe_2O_3 + 3CO \longrightarrow 2Fe + 3CO_2$	
	(c) $C + \frac{1}{2}O_2 \longrightarrow CO$ $\square$ (d) $CO + \frac{1}{2}O_2 \longrightarrow CO_2$ $\square$		(b) $2A1 + Fe_2O_3 \longrightarrow 2Fe + Al_2O_3$	
73.	Consider the following reactions at 1000°C.		(c) $2ZnS + 3O_2 \longrightarrow 2ZnO + 3SO_2$	
	(A) $Zn(s) + \frac{1}{2}O_2(g) \longrightarrow ZnO(s);  \Delta G^{\circ} = -360 \text{ kJ mol}^{-1}$		(d) FeO + SiO <sub>2</sub> $\longrightarrow$ FeSiO <sub>3</sub>	
	(B) $C(s) + \frac{1}{2}O_2(g) \longrightarrow CO(g);  \Delta G^{\circ} = -460 \text{ kJ mol}^{-1}$			
	Choose the correct statement at 1000°C.			
	[M.E.E. (Kerala) 2006]			
Set	II: This set contains questions with two or more	corre	ct answers.	
<i>7</i> 9.	$Ca_3(PO_4)_2$ is:		(a) Cu	
	(a) Thomas slag		(c) Mg	
	(b) used in cement manufacturing	85.	Which of the following ores is/are oxide ore(s)?	
	(c) used in manufacture of phosphorus fertilizer $\Box$		(a) Cassiterite

### **Objective Questions for IIT ASPIRANTS**

<ol> <li>2.</li> </ol>	The ore having two metal atoms is: (a) haematite $\Box$ (b) galena $\Box$ (c) magnetite $\Box$ (d) copper pyrites $\Box$ The metal for which, its property of formation of volatile		<ul><li>(b) Calamine and azurite are carbonates</li><li>(c) Zinc blende and pyrites are sulphides</li><li>(d) Malachite and azurite are ores of copper</li><li>[Hint: Argentite is a sulphide ore]</li></ul>	
	complex is taken into account for its extraction is: (a) cobalt $\Box$ (b) nickel $\Box$ (c) vanadium $\Box$ (d) iron $\Box$ [Hint: Nickel forms Ni(CO)4 (volatile complex) with CO which decomposes to give nickel.]		Chromium is obtained by reducing purified chromite with:  (a) red hot coke □ (b) gaseous hydrogen (c) aluminium powder □ (d) carbon monoxide  Which one of the following reactions is an example	
3.	Zone refining is based on the principle of:  (a) fractional distillation □  (b) partition coefficient □  (c) fractional crystallisation □  (d) chromatographic separation □	,.	calcination process? (a) $2Ag + 2HCl + [O] = 2AgCl + H_2O$ (b) $2Zn + O_2 = 2ZnO$ (c) $2ZnS + 3O_2 = 2ZnO + 2SO_2$	
4.		8.	<ul> <li>(d) MgCO<sub>3</sub> = MgO + CO<sub>2</sub></li> <li>The most electropositive metals are obtained from their oby:</li> <li>(a) high temperature reduction with carbon</li> <li>(b) electrolysis of fused ionic salts</li> <li>(c) self reduction</li> </ul>	
5.	Among the following, the incorrect statement is:  (a) Argentite and cuprite are oxide ores		(d) thermal decomposition	
	1. (d) 2. (b) 3. (c) 4. (a) 5. (a)	6.	(c) 7. (d) 8. (b)	
	1. (d) 2. (b) 3. (c) 4. (a) 5. (a)	6.	(c) 7. (d) 8. (b)	

### Matrix Matching Questions for IIT Aspirants

1. Match the ores of List-I with their composition in List-II:

#### List-I

#### List-II

- (a) Malachite
- (p) Sulphide of copper
- (b) Azurite
- (q) Sulphide of iron
- (c) Chalcopyrites
- (r) Oxide of copper
- (d) Cuprite
- (s) Ore containing carbonate of copper
- 2. Match the ores of List-I with their composition in List-II:

#### List-I

#### List-II

- (a) Iron pyrites
- (p) FeS<sub>2</sub>
- (b) Fool's gold
- (q) Sulphide ore
- (c) Galena
- (r)  $Fe_2O_3$
- (d) Haematite
- (s) Concentrated by froth floatation process
- 3. Match the Column-I with Column-II:

#### Column-I

#### Column-II

- (a) Van Arkel method
- (p) Purification of copper
- (b) Poling
- (q) Refining of silver

- (c) Cupellation
- (d) Solvay process
- 4. Match List-II with List-II:

#### List-I

- (a) Magnesite
- (b) Dolomite
- (c) Corundum
- (d) Bauxite
- 5. Match List-I with List-II:

### List-I

- (Metal)
- (a) Iron
- (b) Lead
- (c) Copper
- (d) Chromium

- (r) Manufacture of Na<sub>2</sub>CO<sub>3</sub>
- (s) Purification of titanium

#### List-II

- (p) Ore of magnesium
- (q) Ore of aluminium
- (r) Oxide ore
- (s) Carbonate ore

#### List-II

(Procedure of extraction)

- (p) Carbon reduction method
- (q) Self reduction
- (r) Thermite process
- (s) Hydrometallurgical process

6. Match the metals of List-I with the process of refining of List-II:

#### List-I

#### List-II

(a) Ni

(p) Mond's process

(b) Ti

(q) Van Arkel method

(c) Zr

- (r) Distillation
- (d) Zn
- (s) Pyrometallurgical process
- 7. Match the metals of List-I with the biological origin of List-II:

#### List-I

#### List-II

- (a) Chromium
- (b) Iron
- (c) Zinc
- (d) Calcium
- (p) Chloroplast
- (q) Haemoglobin

(d-r)

(d-r)

(d-r)

- (r) Eyes of cats and cows
- (s) Prown
- (t) Bones

8. Match the metals of List-I with their distribution in India List-II:

#### List-I

#### List-II

- (a) Gold
- (p) Singhbhum
- (b) Copper
- (q) Kerala coast
- (c) Thorium
- (r) Kolar (Karnataka)
- (d) Calcium (Gypsum)
- (s) Khetri
- (t) Rajasthan
- Match the Column-I with Column-II:

#### [LI.T. 2008]

#### Column-I

- (a)  $PbS \longrightarrow PbO$
- (b)  $CaCO_3 \longrightarrow CaO$
- (c)  $ZnS \longrightarrow Zn$ (d)  $Cu_2S \longrightarrow Cu$
- (p) roasting.
- (q) calcination

Column-II

- (r) carbon reduction
- (s) self reduction

(b-s)

(a-s)

(a-p)

(a-p, s)

- (a-p, q, s) (b-p, q, s)

  - (b-p)

(b-p, q)

- (b-p, s)
  - - (c-q, s)
- (c-q) (c-q, r)

(c-p, q)

(c-q, s)

- (d-r) (d-q, r)
- (a-s)

(a-p)

- (b-q) (b-p, q)
- (c-q)(c-r)

(c-p, r)

(d-t)

(d-r, s)

- (a-r) (a-p)
- (b-p, s, t) (c-q)(b-q)
- (d-t)(d-p, s)
- **Assertion-Reason Type Questions**

The questions given below consist of an Assertion (A) and Reason (R). Use the following key to choose the correct answer:

- (a) If both (A) and (R) are correct and (R) is the correct explanation of (A).
- (b) If both (A) and (R) are correct and (R) is not the correct explanation of (A).
- (c) If (A) is correct but (R) is incorrect.
- (d) If (A) is incorrect but (R) is correct.
- (e) If both (A) and (R) are incorrect.
- 1. (A) All minerals are ores.
  - (R) Ores are minerals from which metal can be extracted conveniently and economically.
- 2. (A) Metals of high purity are obtained by zone refining.
  - (R) Impurities are more soluble in the melt than in pure
- 3. (A) Au, Pt, Ag, etc., are found in free state.

- (R) The metals which are noble and chemically less reactive are found in free state.
- 4. (A) Roasting is a process in which the ore is heated in presence of air.
  - (R) Concentration of sulphide ore is done by calcination method.
- 5. (A) Carnallite is a mineral of magnesium.
  - (R) Sodium is extracted by electrolysis of aqueous sodium chloride solution.
- 6. (A) Ag and Au are extracted by leaching their ores with a dilute solution of NaCN is presence of oxygen.
  - (R) Gangue particles dissolve in NaCN solution.
- 7. (A) Alumina has high conductivity.
  - (R) The mixture of alumina and cryolite is used for electrolytic reduction in order to extract aluminium.
- 8. (A) Oxide ores are concentrated by froth floatation process.
  - (R) In froth floatation process, mineral oil is used.

- 1. (d)

- 3. (a)
- 4. (c)
- 5. (e)
- 6. (c)
- 7. (d)
- 8. (e)

# INTEGER ANDWER Topic Ruestions"

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

- Au + CN<sup>-</sup> + H<sub>2</sub>O + O<sub>2</sub> → [Au(CN)<sub>2</sub>]<sup>-</sup> + OH<sup>-</sup>
  How many CN<sup>-</sup> ions are involved in the above balanced equation?
- 2. In the bauxite ore,  $Al_2O_3xH_2O$ , what is the value of x?
- 3. Iron is ....th most abundant element in the earth's crust.
- 4. In Goldschmidt aluminothermic process, thermite mixture contains—parts Fe<sub>2</sub>O<sub>3</sub> and 1 part aluminium.
- 5. How many different compounds are present in carnallite?

### Auswers

- 1. (8)  $4Au + 8CN^{-} + 2H_2O + O_2 \longrightarrow 4[Au(CN)_2]^{-} + 4OH^{-}$
- 2. (2) Al<sub>2</sub>O<sub>3</sub> 2H<sub>2</sub>O
- 3. (4) Iron is 4th most abundant element in the earth's crust.
- 4. (3) 3 parts Fe<sub>2</sub>O<sub>3</sub> and one part Al.
- 5. (3)  $\frac{\text{MgCl}_2}{1} \cdot \frac{\text{KCl}}{2} \cdot \frac{6\text{H}_2\text{O}}{3}$

2.	The element with atomic number 118(Uuo) has been of			(c) $Al^{3+} > O^{2-} > Na^{+}$	C AI		
	covered recently. Which of the following statements is	not	•	(d) $Na^+ < Al^{3+} < O^{2-}$			
	expected for this element?		10			of D is less than that o	_
	(a) It is a radioactive element		10.	The first ionisation ener	gy (	n b is less than that o	I DC
	(b) It is a solid at room temperature	<u> </u>		because :	.1	ahama than hamillion	
	(c) It's ionisation energy is lowest in group 18			(a) boron has greater nuc			
_	(d) It is more reactive than xenon			(b) In beryllium s-electr		is removed and from c	
3.	Actinides are all:			<i>p</i> -electron is removed		1.1.1.1.1.6	
	(a) man-made elements			(c) p-electron of boron is	mo	re snielded from nucleus	
	(b) have only shortlived isotopes		11	(d) both (b) and (c)	4114-	C	
	(c) the elements from atomic number 90 to atomic num		11.	The values of electronega	_		
	103 and show variable oxidation states			4.0 respectively. The perc	_	· .	5 1S :
	(d) the elements from atomic number 90 onwards and u			(a) 90		(b) 75.5	
	the last element with atomic number 118	. 🗆	10	(c) 50.0	□ 25 Å	(d) 79.5	:
4.	An element has the configuration,		12.	Bond length of HCl is 1.2			
	$1s^2, 2s^22p^6, 3s^23p^63d^5, 4s^2$			(a) 100% ionic		( , , , , , , , , , , , , , , , , , , ,	
	to which block and group of the long form of periodic ta	ble,	10	(c) 83.18% covalent		(d) 50% covalent	
	does this belong?		15.	Which of following does		-	ture:
	(a) $d$ -block, 7th group $\square$ (b) $d$ -block, 5th group			(a) $SO_2Cl_2$		(b) $SiO_4^{2-}$	
	(c) s-block, 2nd group $\Box$ (d) p-block, 15th group	Image: control of the		(c) $SO_4^{2-}$		(d) SF <sub>4</sub>	
5.	Which one of the following statements is wrong?		14.	A molecule which posse	esses	both $sp^3$ and $sp^3d^2$ hyb	bridi-
	(a) Bromine is liquid at room temperature			sation is:			٠
	(b) Carbon has highest melting point amongst non-meta-	als		(a) $PCl_5(g)$		(b) PCl <sub>5</sub> (s)	
				(c) PCl <sub>6</sub>		(d) none of these	
	(c) Fluorine has the highest electron gain enthalpy		15.	The species which does	not :	show paramagnetism?	
	(d) Osmium possesses highest density			(a) $O_2$		(b) O <sub>2</sub> <sup>+</sup>	
6.	The number of elements in each period is:			(c) $O_2^{2-}$		(d) $H_2^+$	
	(a) twice the principal quantum number which is being fi	lled	16.	The bond angles of NH <sub>3</sub>		- · · · · · · · · · · · · · · · · · · ·	er
			10,	(a) $NH_2^- > NH_3 > NH_4^+$			<b>□</b>
	(b) twice the number of atomic orbitals available in	the		(c) $NH_3 > NH_2^- > NH_4^+$		(d) $NH_3 > NH_4^+ > NH_2^-$	
	energy level being filled		17.	Iso-structural pair among			_
	(c) twice the number of atomic mass of the elements		-,,	(a) $XeF_2$ , $IF_2$		(b) NH <sub>3</sub> , BF <sub>3</sub>	
	(d) none of the above			(c) $CO_3^{2-}$ , $SO_3^{2-}$		(d) PCl <sub>5</sub> , ICl <sub>5</sub>	
7.	The 4d-transition series contains elements having ato	mic .	10				
	numbers from :		18.	Among KO <sub>2</sub> , AlO <sub>2</sub> , BaO	2, NO	J <sub>2</sub> unpaired electron is pr	resent
	(a) 40 to 49			in:		4) VO 1 410= 1	
_	(c) 39 to 49			(a) NO <sub>2</sub> and BaO <sub>2</sub>		(b) KO <sub>2</sub> and AlO <sub>2</sub>	
8.	Which is not arranged in the correct sequence?		10	(c) KO <sub>2</sub> only		(d) BaO <sub>2</sub> only	
	(a) $d^5$ , $d^4$ , $d^2$ , $d^1$ —Increasing magnetic moments		19.	The correct hybridisation	z stai	te of sulphur atom in SF <sub>2</sub>	, SF <sub>4</sub>

(b) MO,  $M_2O_3$ ,  $MO_2$ ,  $M_2O_5$ —Increasing acidic strength  $\square$ 

and SF<sub>6</sub> molecules is respectively: (a)  $sp^3d$ ,  $sp^3$ ,  $sp^3d^2$   $\Box$  (b)  $sp^3$ ,  $sp^3d$ ,  $sp^3d^2$ (c)  $sp^3d^2$ ,  $sp^3$ ,  $sp^3d$   $\Box$  (d)  $sp^3d^2$ ,  $sp^3d$ ,  $sp^3$ 

20.	The correct order of lattice energies of the following ionic		(C) Thermite process	(3) Extraction and	
	compounds is:			purification of Ni

- **45.** (A) CaO, which is a cheap and high melting compound, is used in the lining of the furnace.
  - (R) CaO is used as a flux for the removal of acidic impurities like silica in the ore.
- **46.** (A) Auto reduction of ores is used for cinnabar, copper glance and galena ores.
  - (R) The sulphide ores of Hg, Cu and Pb react with their corresponding oxides to give respective metals.
- **47.** (A) Electron gain enthalpies of halogens are maximum in their respective periods.
  - (R) Fluorine has maximum value of electron gain enthalpy.
- 48. (A) Bond order can assume any value including zero.
  - (R) Lower the bond order, larger is the bond length and smaller is the bond energy.
- **49.** (A) In a change from PCl<sub>3</sub> to PCl<sub>5</sub>, the hybrid state of P remains the same.
  - (R) The shape of PCl<sub>3</sub> is pyramidal while that of PCl<sub>5</sub> is trigonal bipyramidal.

INTEGER ANSWER TYPE

Column-I

(a)  $H_3PO_2$ 

(c) H<sub>2</sub>SO<sub>4</sub>

(d)  $H_2SO_3$ 

(b) HI

56. The total number of d-block series in the periodic table are :

(p) Dibasic

(q) Monobasic

(r) Reducing agent

(s) Oxidising agent

Column-II

- 57. How many noble gases are known?
- 58. How many elements are present in third period of periodic table?
- 59. What is the electronegativity of most electronegative element on Pauling scale?
- **60.** The number of total lone pairs in  $ICl_2^-$  is:
- 61. The bond order of CO is:
- 62. How many ionisation energies can carbon have?

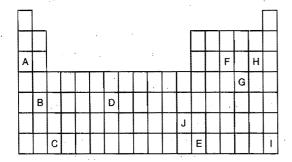

63. Lewis structure of the molecule, COCl<sub>2</sub> is O=C

What is the formal charge on carbon?

- **64.** An element has electronic configuration,  $1s^2$ ,  $2s^22p^6$  $3s^23p^63d^5$ ,  $4s^2$ . To which group of the extended form of periodic table does it belong?
- 65. In Goldschmidt-Aluminothermic process, thermite mixture contains ...... parts Fe<sub>2</sub>O<sub>3</sub> and one part Al.

#### LINKED COMPREHENSION TYPE

#### Passage 1

Analyse the table and answer the following questions:

- **66.** 'C' represents an element named:
  - (a) Yttrium
- (b) Cerium
- (c) Lanthanum
- (d) Actinium
- 67. Which of the following elements is not found in nature but has been obtained by artificial means?
  - (a) C

(c) G

- (d) J
- 68: The element which is known in gaseous state at room temperature is:
  - (a) H

(b) F

(c) G

(d) J

## Passage 2 ·

The amount of positive charge felt by the valence electrons of an atom is the effective nuclear charge. This is less than the actual nuclear charge because core electrons partially shield the valence electrons from the full positive charge of the nucleus. Shielding effect is calculated by applying Slater's rules. Atomic radii depend on the value of n of the valence shell orbitals and the effective nuclear charge experienced by the valence electrons. Atomic radii decrease from left to right in a period and from bottom to top in a group in the periodic table.

Answer the following questions:

- **69.** The atomic size of gallium is smaller than aluminium because:
  - (a) due to poor shielding effect of electrons in d-orbitals, effective nuclear charge increases in Ga

- (b) more shielding effect of d-electrons
- (c) poor shielding effect of f-orbitals in Ga
- (d) high shielding effect of 3s, 3p and 3d-electrons
- 70. The effective nuclear charge for 4s electron of Ca atom will he ·
  - (a) 17.15

(b) 20.0

(c) 2.85

- (d) 2.2
- 71. The maximum atomic radius amongst the following is for:
  - (a) Na

(b) Mg

(c) Al

(d) Si

#### Passage 3

Binary acids contain only hydrogen and another non-metal. Their strengths increase from top to bottom within a group and from left to right across a period. Oxoacids, which contain oxygen atoms in addition to hydrogen and another element, increase in strength as the number of oxygen atoms on the same central atom increases. Delocalisation of negative charge enhances the stability of the oxoacid anions, making them weaker bases and as a result, their conjugate acids are correspondingly stronger. Oxoacids having the same number of oxygen atoms generally increase in strength as the central atom moves from left to right.

Answer the following questions:

- 72. The strongest acid of the following is:
  - (a) H<sub>4</sub>SiO<sub>4</sub>
- (b)  $H_2SO_4$
- (c) HClO<sub>4</sub>
- (d) H<sub>3</sub>PO<sub>4</sub>
- 73. Which is the weakest base among the following?
  - (a) CI

(b) Br

(c) F

- 74. Consider the following compounds:

 $HO - B \qquad HO - C$ 

The electronegativities of A, B and C are in the order C > B > A. The correct order of acid strength of the above compounds is:

- (a) I < II > III
- (b) II > II > I
- (c) III < II < I
- (d) II < III < I

## Passage 4

According to valence bond theory, a covalent bond is formed between two atoms when an atomic orbital of one atom overlaps with an atomic orbital of the other and a pair of electrons with opposite spins is shared between the overlapping orbitals. In general, the better the overlap of the orbitals, the stronger the bond.

Hybrid orbitals are formed by mixing pure s, p and d orbitals. Hybrid orbitals overlap better with other orbitals than the pure atomic orbitals from which they are formed, so the bonds formed by hybrid orbitals are stronger than those formed by ordinary atomic orbitals. Two types of bonds sigma and  $\pi$ -bonds are formed by overlapping. Sigma bonds are always stronger than  $\pi$ -bonds.

#### Revision Exercise: 1 (Chapter 1 to 4)

Answer the following questions:

- 75. The orbitals of same energy level providing the most efficient overlapping are:
  - (a)  $sp^3-sp$
- (b)  $sp^2 sp^2$
- (c) *sp-sp*
- (d) all of these
- **76.** Strongest bond is formed by the head on overlapping of:
  - (a) 2s and 2s orbitals
- (b) 2p and 2p orbitals
- (c) 2s and 2p orbitals
- (d) all of these

- 77. A  $\pi$ -bond is formed by overlap of :
  - (a) s-s orbitals
  - (b) s-p orbitals
  - (c) p-p orbitals in sidewise manner
  - (d) p-p orbitals in end to end fashion

# uswers with Him

- (d) Filling of 3*d*-orbital starts from the element with atomic number 21.
- 2. (b)
- (c) These are 5f-elements from at. no. 90 to at. no. 103. Some of the members are found in nature and few of the isotopes are long-lived.
- (a) The last electron enters d-orbital, thus the element belongs to *d*-block and the group  $(3d^5 4s^2) = 5 + 2 = 7$
- 5. (c) Chlorine and not fluorine has the highest electron gain enthalpy.
- 6.
- 7. (b)
- (a) Magnetic moment depends on the number of singly occupied 8. orbitals.
- 9. (a) Ionic size decreases in isoelectronic ions when z/e ratio increases.
- (d) It is easier to remove an electron from p-orbital as it is far from nucleus than s-orbital. It is also easier to remove electron from a singly occupied orbital than a paired orbital.
- (d) % ionic character =  $16(4.0 1.0) + 3.5(4.0 1.0)^2$ = 48 + 31.5 = 79.5
- 12. (c)  $e = \frac{\mu}{d} = \frac{1.03 \times 10^{-18}}{1.275 \times 10^{-8}} = \frac{1.03}{1.275} \times 10^{-10} \text{ esu}$ % ionic character  $= \frac{100}{4.803 \times 10^{-10}} \times \frac{1.03 \times 10^{-10}}{1.275} = 16.82$ i.e., 83.18% covalent.
- 13. (d) S in SF<sub>4</sub> undergoes  $sp^3d$  hybridisation. It has a see-saw shape.
- (b)  $PCl_5(s)$  is an ionic species, *i.e.*, [PCl<sub>4</sub>]<sup>+</sup>[PCl<sub>6</sub>]<sup>-</sup>. In [PCl<sub>4</sub>]<sup>+</sup>, P undergoes sp<sup>3</sup> hybridisation while in  $[PCl_6]^-$ , P is in  $sp^3d^2$  hybridised state.
- (c)  $O_2^{2-}$  has configuration

$$KK\sigma(2s)^2 \mathring{\sigma}(2s^2) \sigma(2p_z)^2 \pi(2p_x)^2 \pi(2p_y)^2 \mathring{\pi}(2p_x)^2 \mathring{\pi}(2p_y)^2$$

All the molecular orbitals are doubly occupied hence  $O_2^{2-}$  ion is diamagnetic.

- 16. (b) N in all the three species is in  $sp^3$  hybridised state but in NH<sub>4</sub> no lone pair is present on it but in NH3, one lone pair and in NH<sub>2</sub>, two lone pairs of electrons are present. Thus, bond angle subsequently decreases.
- 17. (a) XeF<sub>2</sub> —Linear; IF<sub>2</sub> —Linear
  - NH3-Pyramidal; BF3-Triangular planar
  - CO<sub>3</sub><sup>2</sup>—Triangular planar; SO<sub>3</sub><sup>2</sup>—Pyramidal
  - PCl5—Trigonal bipyramidal; ICl5—Square pyramidal
- 18. (c) KO<sub>2</sub> has K<sup>+</sup>O<sub>2</sub> structure. O<sub>2</sub> possesses one unpaired electron.
- (b)  $SF_2 sp^3$ ;  $SF_4 sp^3d$ ;  $SF_6 sp^3d^2$
- 20. (d)

- 22. (a)
- (a) The weakest acid furnishes strongest base anion.
- 24. (d)
- 25. (b)

#### Introduction

Hydrogen is the lightest element. It is most abundant element in the universe, comprising nearly 90% of all atoms and is the third most abundant element after oxygen and silicon on the surface of the earth. Most planets (stars), including our source of energy the sun, consist primarily of hydrogen. The hydrogen in the sun is the fuel for the fusion reactions that produce the life-sustaining energy which reaches our planet, *i.e.*, on the earth. The most important source of hydrogen on earth is water. The majority of hydrogen is found in oceans combined with oxygen as water.

Hydrogen atoms are the simplest of the all atoms. It is the first member of the periodic table as its atomic number is one. It has the simplest atomic structure among all the known elements. In atomic form, it consists of only one proton and a single planetary electron. Hydrogen, therefore, has the simplest electronic configuration,  $1s^1$ . The atomic form of the hydrogen exists only at very high temperatures. Normally, the elemental hydrogen is a diatomic molecule,  $H_2$  (commonly known as **dihydrogen**), the product of an exothermic reaction between H-atoms:

$$H(g) + H(g) \longrightarrow H_2(g); \Delta H^\circ = -436.4 \text{ kJ mol}^{-1}$$

The combustion of hydrogen produces more heat per gram than any other fuel. As compared to hydrocarbons, it is a "Clean fuel" because the product, water is environmentally benign. Higher consumption and least supply of hydrocarbons indicate that hydrogen gas may become the favourite fuel of the twenty-first century.

The reaction of hydrogen with oxygen to form water is an example of a reaction that requires the input of energy to get started, however, once it does, the reaction is rapid and exothermic. Because it is such an exothermic and the product is a gas, it is an ideal rocket fuel.

Hydrogen forms more compounds than any other element. These include the organic compounds, biologically important compounds and acids and bases. Hydrogen is of great industrial importance and it is said that global energy crisis can be overcome to a great extent by the use of hydrogen as a source of energy.

**Note:** Unipositive hydrogen ion (H<sup>+</sup>) i.e., proton has a very small size ( $\sim 1.5 \times 10^{-3}$  pm) compared to normal atomic and ionic sizes of 50 to 220 pm. It does not exist freely and is always associated with other atoms or molecules.

# POSITION OF HYDROGEN IN PERIODIC TABLE

There are only two elements in the first period of the periodic table, hydrogen and helium. Hydrogen is quite reactive but helium is inert. There is no difficulty in relating the structure and properties of helium with other noble gases in group 0 (or 18th), but properties of hydrogen are such that it cannot be correlated with elements of any of the main groups of the periodic table.

The configuration of hydrogen (1s<sup>1</sup>) is responsible for its dual nature, *i.e.*, either the electron can be lost behaving as electropositive element like alkali metals or the electron can be gained as to complete 1s subshell behaving as electronegative element like halogens. The position of hydrogen is not fixed in the periodic table, sometimes it is placed with alkali metals in IA group and sometimes with halogens in VIIA (or 17th) group as it resembles with alkali metals as well as with halogens. However, hydrogen exhibits other properties which differ from both alkali metals and halogens.

#### Similarities with alkali metals

On account of the following similarities of hydrogen with alkali metals, hydrogen is placed on the top of IA group.

(i) Electronic configuration: Like the alkali metals, hydrogen has only one electron in the outer shell.

Element H Li Na K Rb Cs 1; 2, 1; 2, 8, 1; 2, 8, 8, 1; 2, 8, 18, 8, 1; 2, 8, 18, 18, 18, 18, 18 Electronic 
$$1s^1$$
;  $2s^1$ ;  $3s^1$ ;  $4s^1$ ;  $5s^1$ ;  $6s^1$  configuration

(ii) Electropositive character: Like the alkali metals hydrogen has a tendency to lose its only one electron to form unipositive ion.

$$H \xrightarrow{-e} H^{+}$$

$$Li \xrightarrow{-e} Li^{+}.$$

$$Na \xrightarrow{-e} Na^{+}$$

Halides of both hydrogen and the alkali metals yield positive ions in aqueous solutions.

$$HCl \rightleftharpoons H^+ + Cl^-$$
  
 $NaCl \rightleftharpoons Na^+ + Cl^-$ 

During electrolysis, these ions are discharged at cathode. This shows that hydrogen and alkali metals both have electropositive character.

- (iii) Valency: Because of the formation of unipositive cation both hydrogen and alkali metals show electrovalency +1.
- (iv) Oxidation state: Hydrogen, like alkali metals when combines with electronegative elements shows +1 oxidation state.
- (v) Affinity for non-metals: Hydrogen as well as alkali metals have a strong affinity for nonmetals. For example, both

hydrogen and alkali metals combine with halogens to form halides, with oxygen to give oxides and with sulphur to give sulphides.

> HCl; NaCl; KCl H<sub>2</sub>O; Na<sub>2</sub>O; K<sub>2</sub>O H<sub>2</sub>S; Na<sub>2</sub>S; K<sub>2</sub>S

(vi) Reducing nature: Hydrogen, like alkali metals, acts as a reducing agent. Oxides of less reactive metals are reduced by hydrogen.

$$CuO + H_2 \longrightarrow Cu + H_2O$$
;  $CuO + 2Na \longrightarrow Cu + Na_2O$ 

#### Differences with Alkali Metals

(i) Ionisation energy: The ionisation energy of hydrogen is very high in comparison to alkali metals.

Element Hydrogen Lithium Sodium Potassium IE (kJ mol<sup>-1</sup>) 1312 520 495 418

- (ii) Nonmetallic character: Hydrogen is a nonmetal while alkali metals are metals.
- (iii) Atomicity: Hydrogen is diatomic in nature  $(H_2)$  while alkali metals are monoatomic.
- (iv) Nature of oxide: The oxide of hydrogen is neutral while oxides of alkali metals are basic in nature.
- **(v) Nature of compounds:** The compounds of hydrogen with halogens (HF, HCl, HBr, HI) are low boiling covalent compounds while halides of alkali metals are high melting ionic solids. LiF, NaCl, KBr, etc., are ionic solids.

## Similarities with Halogens

On account of the following similarities and to avoid a long gap in the first period before the second member of the period (helium), it is placed in VIIA (or 17th) group above fluorine.

- (i) Nonmetallic character: Hydrogen is a nonmetal like halogens.
- (ii) Electronic configuration: Hydrogen resembles the halogens in having one electron less than the next inert gas in its atom.

			Inert gas
1	H	1	2 He 2
9	F	2, 7	10 Ne 2, 8
17	Cl	2, 8, 7	18 Ar 2, 8, 8
35	Br	2, 8, 18, 7	36 Kr 2, 8, 18, 8

- (iii) Diatomic nature: Hydrogen forms a diatomic molecule in the elementary state similar to the halogens in which two atoms are linked together by single covalent bond (H<sub>2</sub>, F<sub>2</sub>, Cl<sub>2</sub>, Br<sub>2</sub>).
- (iv) Electronegative nature: Hydrogen can gain an electron and forms a negative ion like the halogens.

$$H + e \longrightarrow H^{-}; \qquad Cl + e \longrightarrow Cl^{-}$$

In the electrolysis of fused metal hydrides, hydrogen is discharged on the anode like the halogens in the electrolysis of the fused metal halides.

NaH 
$$\rightleftharpoons$$
 Na<sup>+</sup> + H<sup>-</sup> (Anode 2H<sup>-</sup>  $\longrightarrow$  H<sub>2</sub> + 2e)  
NaCl  $\rightleftharpoons$  Na<sup>+</sup> + Cl<sup>-</sup> (Anode 2Cl<sup>-</sup>  $\longrightarrow$  Cl<sub>2</sub> + 2e)

(v) Ionisation potential: The ionisation potential of hydrogen is 13.5 eV. The value is nearer to the halogens.

[Alkali metals have low values of ionisation potentials]

(vi) Similar covalent compounds and mutual replacement: Hydrogen forms several covalent compounds similar to those of halogens. For example:

$$CH_4$$
  $SiH_4$   $GeH_4$   
 $CCl_4$   $SiCl_4$   $GeCl_4$ 

Hydrogen and halogens are mutually replaceable in many covalent compounds of hydrogen and halogens.

$$CH_4 \overset{Cl}{\underset{H}{\rightleftharpoons}} CH_3Cl \overset{Cl}{\underset{H}{\rightleftharpoons}} CH_2Cl_2 \overset{Cl}{\underset{H}{\rightleftharpoons}} CHCl_3 \overset{Cl}{\underset{H}{\rightleftharpoons}} CCl_4$$

(vii) Oxidation state or number: Hydrogen, like halogens show -1 oxidation state in similar compounds.

(viii) Valency: Hydrogen, like halogens shows electrovalency as well as covalency. Hydrogen forms electrovalent compounds with strongly electropositive elements like alkali and alkaline earth metals.

Hydrogen forms covalent compounds with nonmetals.

$$\begin{array}{ccc} CH_4 & NH_3 & PH_3 \\ CCl_4 & NCl_3 & PCl_3 \end{array} \right\} \ Covalent \ compounds$$

# Differences with Halogens

- (i) Less electronegative: Hydrogen is less electronegative than halogens as it has less tendency to form H<sup>-</sup> ion. Halogens readily accept electron and form halide ions (X<sup>-</sup>).
- (ii) Nature of oxides: The oxides of halogens are acidic in nature while oxide of hydrogen is neutral.

(iii) Absence of unshared pairs of electrons: The hydrogen molecule does not have any unshared pair of electrons while in the molecules of halogens unshared pairs of electrons are present.

No doubt, hydrogen resembles alkali metals and halogens both but it is not so electropositive as alkali metals **due to high**  value of ionisation potential, similarly it is not so electronegative as halogens due to low value of electron affinity. Both the characters are equally developed in hydrogen as evident from the nature of its oxide which is neutral.

Na<sub>2</sub>O—basic (because sodium is highly electropositive)

Cl<sub>2</sub>O<sub>7</sub>—acidic (because chlorine is highly electronegative)

It is, therefore, suggested that hydrogen be alloted a separate position and not grouped with either alkali metals or halogens. Thomson assigned a separate independent position to hydrogen on the top of periodic table as shown below:

This does not disturb the symmetry of the periodic table and \_\_\_\_ there is no violation of periodic law.

In some respects, hydrogen also resembles carbon of the group IV, since both have a half filled shell of electrons.

H 1 (half of first shell maximum capacity of 2 electrons) C 2,4 (half of second shell maximum capacity of 8 electrons).

There are a number of similarities between hydrogen and organometallic compounds since the groups CH<sub>3</sub>— and H—both have one remaining valency. Thus, the hydride is often considered as part of a series of organometallic compounds, for example, LiH, LiMe, LiEt; NH<sub>3</sub>, NMe<sub>3</sub>, NEt<sub>3</sub> or SiH<sub>4</sub>, CH<sub>3</sub>SiH<sub>3</sub>, (CH<sub>3</sub>)<sub>2</sub>SiH<sub>2</sub>, (CH<sub>3</sub>)<sub>3</sub>SiH, (CH<sub>3</sub>)<sub>4</sub>Si. Thus, hydrogen position is not fixed and hydrogen is best treated as a group on its own. Hydrogen is sometimes referred as a **'roque element'**.

# 5.2 DISCOVERY AND OCCURRENCE

Hydrogen was prepared by **Henry Cavendish** in 1766 by the action of acids on metals. It was named 'inflammable air'. **Lavoisier** named it hydrogen (hydra = water, gennas = maker) meaning water maker.

Hydrogen is the most abundant element in the universe. It occurs in nature in the free state as well as in combined state. In free state, it is present in minute quantity in air, volcanic gases and natural gas. Sun's atmosphere contains 90% of hydrogen. It is found most commonly in combination with oxygen as water. Hydrogen occurs in variety of compounds such as it occurs in mineral oils and is present in almost all the organic materials such as hydrocarbons, carbohydrates, fats, proteins, etc. Hydrogen is, thus, an essential constituent of all living things along with carbon, nitrogen and oxygen. Hydrogen is also an essential constituent of all acids and alkalies.

# 5.3 PREPARATION

There are three main sources from which hydrogen may be prepared. These are;

(i) Water (ii) Acids and (iii) Alkalies.

## (i) Hydrogen from Water

(a) Cold water reacts with alkali and alkaline earth metals to evolve hydrogen. The reactions are vigorous. To minimise the rate of reaction, alkali metals are used in the form of amalgams.

$$2Na(Hg) + 2H_2O = 2NaOH + H_2 \uparrow$$
  
Sodium amalgam

In the amalgam, only a small surface of the metal is exposed and therefore, the reaction is slow.

**(b)** Hot water or steam, when passed over hot metals like Zn, Fe, Mn, Co, Cr, Sn, etc., is decomposed to liberate hydrogen.

$$Zn + H_2O \longrightarrow ZnO + H_2\uparrow$$
  
 $3Fe + 4H_2O \longrightarrow Fe_3O_4 + 4H_2\uparrow$   
Red hot Steam

When steam is passed over white hot coke, hydrogen is produced in the form of water gas.

$$\begin{array}{ccc} C & + & H_2O & \longrightarrow & \underbrace{CO + H_2}_{Water\ gas} \end{array}$$

(c) By action of water on ionic hydrides: Ionic hydrides on hydrolysis with water evolve hydrogen. The hydride ion is oxidised to hydrogen. These reactions may be regarded as acid-base reactions.

$$\begin{array}{c} \text{NaH} + \text{H}_2\text{O} & \longrightarrow \text{NaOH} + \text{H}_2\\ \text{LiH} + \text{H}_2\text{O} & \longrightarrow \text{LiOH} + \text{H}_2\\ \text{CaH}_2 + 2\text{H}_2\text{O} & \longrightarrow \text{Ca(OH)}_2 + 2\text{H}_2\\ \text{(Hydrolith)} \end{array}$$

$$[H^- + H_2O \longrightarrow H_2 + OH^-]$$

Sodium borohydride also reacts with water to evolve hydrogen.

$$NaBH_4 + 2H_2O \longrightarrow NaBO_2 + 4H_2$$

(d) By the reaction of methane and steam: Both react at high temperature in presence of suitable catalyst to form hydrogen along with carbon monoxide.

$$CH_4 + H_2O \longrightarrow CO + 3H_2$$

(e) By electrolysis of water: Water is a bad conductor of electricity. Water is made a conductor either by addition of an acid or an alkali. The water containing a small amount of an acid or alkali (about 15–20%) is electrolysed in an electrolytic cell. The anode and cathode are separated by asbestos diaphragm. The cathode used is usually of iron and anode usually of nickel. The process is used at places where electric supply is cheap and easily available.

Water containing sulphuric acid: Ions present are  $H^+$ ,  $OH^-$  and  $SO_4^{2-}$ . On passing electricity  $H^+$  ions move towards cathode while  $OH^-$  and  $SO_4^{2-}$  ions move towards anode.

At cathode, hydrogen ions are discharged to give hydrogen gas.

$$2H^+ + 2e \longrightarrow 2H \longrightarrow H_2$$
  
**At anode,** OH<sup>-</sup> ions are discharged to give oxygen gas.  
OH<sup>-</sup>  $\longrightarrow$  OH + e  
 $4OH \longrightarrow 2H_2O + O_2$ 

[SO<sub>4</sub><sup>2</sup> ions are not discharged on anode as their discharge potential is higher than that of OH ions]

Water containing potassium hydroxide: Ions present are  $K^+$ ,  $OH^-$  and  $H^+$ . When current is passed,  $OH^-$  ions move towards anode while  $H^+$  and  $K^+$  ions move towards cathode.

At anode, OH ions are discharged and oxygen is evolved.

$$4OH \longrightarrow 2H_2O + O_2 + 4e$$

At cathode, H<sup>+</sup> ions are discharged and hydrogen is evolved.

$$2H^+ + 2e \longrightarrow H_2 \uparrow$$

[K<sup>+</sup> ions are not discharged as their discharge potential is higher than that of H<sup>+</sup> ions]

#### (ii) Hydrogen from Acids

(a) The metals which are reactive and occupy their position above hydrogen in the electrochemical series such as alkali metals, alkaline earth metals, Zn, Mg, Fe, etc., react with dil. HCl or dil.  $H_2SO_4$  to evolve hydrogen.

$$Mg + 2HCl \longrightarrow MgCl_2 + H_2 \uparrow$$
  
 $Fe + H_2SO_4 \longrightarrow FeSO_4 + H_2 \uparrow$   
 $Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2 \uparrow$ 

 $M \to M^{2+} + 2e$  [M is electropositive and has the tendency to  $2H^+ + 2e \to H_2$  lose electrons. These electrons are accepted by protons given by dil. acids to yield hydrogen.]

(b) Mn and Mg react with dil. HNO<sub>3</sub> to evolve hydrogen.

## (iii) Hydrogen from Alkalies

Zn, Al, Sn, Pb, Si (amphoteric metals) react with boiling NaOH or KOH to evolve hydrogen.

$$Zn + 2NaOH = Na_2ZnO_2 + H_2 \uparrow$$

$$Sodium zincate$$

$$2Al + 2NaOH + 2H_2O = 2NaAlO_2 + 3H_2 \uparrow$$

$$Sodium meta-$$

$$aluminate$$

$$Sn + 2NaOH + H_2O = Na_2SnO_3 + 2H_2 \uparrow$$

$$Sodium stannate$$

$$Pb + 2NaOH + H_2O = Na_2PbO_3 + 2H_2 \uparrow$$

$$Sodium plumbate$$

$$Si + 2NaOH + H_2O = Na_2SiO_3 + 2H_2 \uparrow$$

$$Sodium silicate$$

**Uyeno's method:** Very pure hydrogen is obtained with rapidity by the action of caustic potash on scrap aluminium. This method is used for military purposes.

$$2AI + 2KOH + 2H_2O = 2KAIO_2 + 3H_2 \uparrow$$

#### Laboratory Method

Hydrogen is prepared in the laboratory by the action of dilute sulphuric acid on granular (commercial) zinc in the woulfebottle. It is collected by downward displacement of air as it is lighter than air. In place of woulfe bottle, Kipp's apparatus can also be used. The apparatus should always be air tight and there should not be any flame near the apparatus otherwise explosion may occur. **Dilute H<sub>2</sub>SO<sub>4</sub> does not react with pure zinc.\*** In case of pure zinc, the addition of few drops of chloroplatinic acid or copper sulphate solution brings about the reaction.

**Purification of hydrogen gas:** Hydrogen prepared in the laboratory from granular zinc consists of a number of impurities such as AsH<sub>3</sub>, PH<sub>3</sub>, H<sub>2</sub>S, SO<sub>2</sub>, CO<sub>2</sub>, oxides of nitrogen, etc. To remove these impurities, the hydrogen is passed through three bottles containing AgNO<sub>3</sub> solution, Pb(CH<sub>3</sub>COO)<sub>2</sub> solution and KOH solution, respectively. AgNO<sub>3</sub> solution removes PH<sub>3</sub> and AsH<sub>3</sub>; Pb(CH<sub>3</sub>COO)<sub>2</sub> solution removes H<sub>2</sub>S; and the KOH solution removes CO<sub>2</sub>, SO<sub>2</sub> and oxides of nitrogen. Finally, hydrogen is collected over P<sub>2</sub>O<sub>5</sub> or anhydrous CaCl<sub>2</sub> as to remove the traces of moisture present in the hydrogen.

**Example 1.** In the laboratory, for the preparation of hydrogen from granular zinc, why the following acids cannot be used and which is the most suitable acid for this purposes:

(a) Conc.  $H_2SO_4$ 

(b) Conc. HCl

(c) Nitric acid.

**Solution:** (a) Conc. H<sub>2</sub>SO<sub>4</sub> is not used because a part of the acid gets reduced to sulphur dioxide.

$$H_2SO_4 + H_2 \longrightarrow 2H_2O + SO_2$$
(Conc.)

(b) Hydrogen liberated by the action of conc. HCl on zinc will be impure as it will contain fumes of volatile HCl. Moreover, ZnCl<sub>2</sub> formed is insoluble in conc. HCl. It will form a coating on zinc and the reaction stops after sometime.

$$Zn + 2HCl \longrightarrow ZnCl_2 + H_2$$

(c) HNO<sub>3</sub> plays a double role. It acts as an acid and as an oxidising agent. The hydrogen (nascent) first formed reduces the nitric acid into various oxides.

$$2HNO_3 + 2H \longrightarrow 2NO_2 + 2H_2O$$
  
 $2HNO_3 + 6H \longrightarrow 2NO + 4H_2O$ 

Thus, the most suitable acid is dilute H<sub>2</sub>SO<sub>4</sub>.

## Preparation of Pure Hydrogen

Pure hydrogen is obtained,

(i) by carrying electrolysis of barium hydroxide, Ba(OH)<sub>2</sub>, solution in a U-tube using platinum electrodes or nickel electrodes. The gas liberated at the cathode is passed over heated platinum gauze as to remove oxygen if present as an impurity in the form of water which is removed by passing the

gas through  $P_2O_5$ . Barium hydroxide,  $Ba(OH)_2$  is preferred to sodium hydroxide or potassium hydroxide because if any amount of  $CO_2$  is absorbed, the  $BaCO_3$  produced, being insoluble, settles down and does not interfere with electrolytic process.

(ii) by action of water on NaH,

$$NaH + H_2O \longrightarrow NaOH + H_2\uparrow$$

(iii) by Uyeno's method,

$$2Al + 2KOH + 2H_2O \longrightarrow 2KAlO_2 + 3H_2\uparrow$$

(iv) by the action of pure dilute  $H_2SO_4$  on magnesium ribbon.

$$Mg + H_2SO_4$$
 (dil.)  $\longrightarrow MgSO_4 + H_2$ 

## MANUFACTURE OF HYDROGEN

Large quantities of hydrogen are required these days in industry for various purposes. Water is found in abundance and is the cheapest raw material from which hydrogen can be obtained. Many methods have been proposed for the commercial production of hydrogen, among which the important ones are described below:

(i) Lane's process: In this process, steam is passed over hot iron. Iron decomposes steam with the formation of magnetic oxide (Fe<sub>3</sub>O<sub>4</sub>) and hydrogen. The temperature of iron is maintained between 550 to 800°C. This reaction is termed gassing reaction and time alloted for this reaction is about 10 minutes.

3Fe + 
$$4H_2O$$
 =  $Fe_3O_4$  +  $4H_2\uparrow$  Gassing Magnetic Oxide

Iron is regenerated by reducing magnetic oxide with water gas  $(CO + H_2)$ . This reaction is called **vivifaction** and time alloted for this reaction is about 20 minutes.

$$\begin{array}{l} Fe_{3}O_{4} + 4CO = \ 3Fe + 4CO_{2} \\ Fe_{3}O_{4} + 4H_{2} = \ 3Fe + 4H_{2}O \end{array} \} \ ^{Vivifaction}$$

This iron is again used for decomposition of steam. In order to make the process continuous, the above two reactions are carried out alternatively using two or more furnaces.

(ii) Bosch's process (water-gas reactions): The considerable quantity of commercial hydrogen is obtained by the use of this method. Water gas is produced first by passing steam over hot coke at 1000°C. The temperature is not allowed to fall below 1000°C.

$$C + H_2O \longrightarrow \underbrace{CO + H_2}_{Water\ gas}$$

<sup>\*</sup>Pure zinc reacts to produce hydrogen very slowly and in small amount. The reason is that the initially formed gaseous hydrogen forms an extremely thin film on the surface of zinc which prevents the further dissolution of zinc in acid. Moreover, as a result of high over voltage established before the hydrogen can evolve from zinc surface, the discharge of H<sup>+</sup> ions or at least the combination of hydrogen atoms to form H<sub>2</sub> molecules cannot occur on pure zinc surface, so, granular zinc is preferably used. If a little CuSO<sub>4</sub> is added, a thin layer of copper is formed on zinc surface. Zinc-copper couple reacts readily with dilute acid.

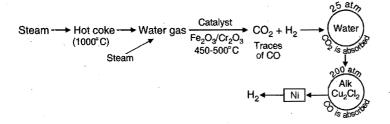

Water gas\* is mixed with twice its volume of steam and passed over a mixture of ferric oxide and chromium oxide heated to 500°C. The mixture acts as a catalyst and helps in the conversion of carbon monoxide to carbon dioxide.

$$\underbrace{H_2 + CO}_{\text{Water gas}} + \underbrace{H_2O}_{\text{Steam}} \xrightarrow{\text{Catalyst}} CO_2 + 2H_2$$

CO<sub>2</sub> dissolves in water under pressure. The mixture of CO<sub>2</sub> and H<sub>2</sub> is passed through water under a pressure of 25–30 atmospheres. CO<sub>2</sub> dissolves completely in water. Traces of CO present in hydrogen are removed by passing the gas through ammonical cuprous chloride solution under a pressure of 200 atmospheres.

The hydrogen manufactured by this method is utilised for the synthesis of ammonia in which CO acts as a poison for the catalyst. To make hydrogen completely free from CO, it is passed over nickel catalyst where any amount of CO left is converted to methane.

$$CO + 3H_2 \longrightarrow CH_4 + H_2O$$

(iii) From natural gas using steam reforming process: The hydrogen on a massive industrial scale is prepared by using the steam-reforming process. This is a recent method. In this process steam and hydrocarbons from natural gas or petroleum react at high temperature and pressure in the presence of catalyst to form carbon monoxide and hydrogen. Natural gas mainly consists of methane (CH<sub>4</sub>). Hydrogen is obtained from natural gas either by partial oxidation or by cracking.

$$\begin{array}{c} \text{CH}_4 + \text{H}_2\text{O} \xrightarrow{\text{Ni-Cr}} \text{CO} + 3\text{H}_2 \\ \text{Steam} \end{array}$$

$$\begin{array}{c} \text{CO} + \text{H}_2\text{O} \xrightarrow{\text{Ni-Cr}} \text{CO}_2 + \text{H}_2 \\ \text{CH}_4 \xrightarrow{\text{Cracking}} \text{CO}_2 + \text{CO}_2$$

Natural gas is mixed with steam and passed over a catalyst at about 800-900°C. The CO<sub>2</sub> and CO are removed by the method as described in Bosch's process.

(iv) Electrolysis of water: See section 5.3 (i) (e).

(v) As a byproduct: Sodium hydroxide is manufactured by carrying electrolysis of an aqueous solution of sodium chloride in Nelson cell (Fig. 6.1) or Castner-Kellner cell (Fig. 6.2). Hydrogen and chlorine are the byproducts of this industry.

Hydrogen is also obtained as a byproduct in the manufacture of sodium by electrolysis of fused sodium hydroxide by Castner's process.

(vi) Relatively smaller quantities of hydrogen are obtained by passing a 1:1 molar mixture of vapourised methanol and water over a base metal chromite type catalyst at 400°C. The mixture of hydrogen and carbon monoxide obtained is made to react with steam to give CO<sub>2</sub> and more hydrogen.

CH<sub>3</sub>OH 
$$\xrightarrow{400^{\circ}\text{C}}$$
 CO + 2H<sub>2</sub>
CO + H<sub>2</sub>O  $\xrightarrow{400^{\circ}\text{C}}$  CO<sub>2</sub> + H<sub>2</sub>

The CO<sub>2</sub> and CO are removed by the method described in Bosch's process.

These days about 77% of the commercial hydrogen is produced from petrochemicals, 18% from coal, 4% from electrolysis of aqueous solutions and 1% from other sources.

# 5.5 PROPERTIES OF HYDROGEN

## **Physical Properties**

- (a) It is a colourless, odourless and tasteless gas.
- (b) It is only slightly soluble in water, about 2 volumes in 100 volume of water at 0°C.
  - (c) It is lightest of all elements.

Density = 
$$0.08987 \text{ gL}^{-1}$$

(d) It is diatomic in nature.

$$C_p/C_v = \gamma = 1.40$$

(e) It has low melting and boiling points,

b.pt. = 
$$-252.5$$
°C (20.5 K)  
m.pt.=  $-259.0$ °C (14.0 K)

(f) The various physical constants are:

Ionisation potential 13.54 eV or 313 kcal mol<sup>-1</sup>
Electron affinity 17.3 kcal mol<sup>-1</sup> or 72 kJ mol<sup>-1</sup>
Electronegativity 2.1
Critical temperature -236.9°C
Bond energy, H—H 436 kJ mol<sup>-1</sup>
Bond length, H—H 74 pm

(g) Certain metals like palladium, platinum, iron, cobalt, etc., can adsorb large quantities of hydrogen. Palladium can adsorb 1000 times its own volume of hydrogen. The adsorbed hydrogen is called **occluded hydrogen** and is more active than ordinary hydrogen. This property can be used for the purification of hydrogen because only pure hydrogen is adsorbed.

<sup>\*</sup>All mixtures of CO and H<sub>2</sub> irrespective of their composition are called now-a-days synthesis gas or Syn gas. Syn gas can also be produced from sewage, sawdust, scrap wood, newspaper, etc.

#### 25 Chemical Properties

(a) Combustion: Hydrogen is inflammable or combustible gas. It burns with blue flame in oxygen atmosphere. Hydrogen, however, does not help in burning. If a burning splinter is introduced in a jar full of hydrogen, the splinter goes out while the gas burns on the mouth of the jar. On account of hydrogen burning, water is formed.

$$2H_2 + O_2 = 2H_2O$$

**(b)** Combination reactions: Hydrogen is not a very active element and does not react readily with other elements. The H—H bond dissociation enthalpy (436 kJ mol<sup>-1</sup>) is the highest for a single bond between two atoms of any element. It's dissociation is only 0.081% at 2000 K and increases to 95.5% at 5000 K.

$$H_2(g) \xrightarrow{5000 \text{ K}} 2H(g)$$

Therefore, most of the reactions of dihydrogen occur at high temperatures.

Under suitable conditions, hydrogen can be made to combine with metals and nonmetals both. (i) Alkali and alkaline earth metals (with the exception of beryllium) directly combine with hydrogen when heated in its atmosphere. The compounds formed are called hydrides.

$$2Li + H_2 = 2LiH;$$
  $Ca + H_2 = CaH_2$   
 $2Na + H_2 = 2NaH;$   $Ba + H_2 = BaH_2$ 

These hydrides are electrovalent compounds, conduct electricity in fused state. (ii) Non-metals like halogens, oxygen, sulphur, nitrogen, etc., directly combine with hydrogen under definite set of conditions and form stable covalent compounds. With fluorine, hydrogen combines readily even at low temperature while the combination with chlorine takes place in presence of sunlight or on heating. Similarly, with bromine it combines on heating while with iodine it combines when heated in presence of a catalyst.

$$H_2 + X_2 = 2HX$$
;  $X = F$ , Cl, Br or I

The reactivity of halogens towards dihydrogen decreases in the order:

$$F_2 > Cl_2 > Br_2 > I_2$$

Hydrogen combines with sulphur on ignition.

$$H_2 + S = H_2S$$

It combines with nitrogen under high pressure and in presence of a catalyst at 500°C.

$$N_2 + 3H_2 \stackrel{\text{Fe as catalyst}}{\underbrace{200 \text{ atm.}}} 2NH_3$$

It combines with carbon at about 1200°C to form methane in small amounts.

$$C + 2H_2 = CH_4$$

(c) Reducing nature: As hydrogen has great affinity for oxygen, it is suitable for removing oxygen. The oxides of less

electropositive metals such as copper, tin, iron, lead, etc., are reduced to the metals when heated in hydrogen.

$$PbO + H_2 = Pb + H_2O$$
  
 $CuO + H_2 = Cu + H_2O$   
 $Fe_3O_4 + 4H_2 = 3Fe + 4H_2O$ 

[Note: The oxides of strongly electropositive metals such as those of alkali and alkaline earth metals are not reduced by dihydrogen.]

Numerous substances are reduced or hydrogenated by hydrogen in presence of suitable catalysts. The unsaturated fats are changed to saturated fats in the presence of finely divided nickel.

Unsaturated + 
$$H_2$$
  $\xrightarrow{\text{Ni}}$   $\xrightarrow{\text{Catalyst}}$  Saturated fat (Vanaspati ghee)

$$CH_2 = CH_2 + H_2 \xrightarrow{\text{Ni or Pt or Pd}} CH_3 - CH_3$$
Ethane

$$CH = CH + 2H_2 \xrightarrow{\text{Ni or Pt or Pd}} CH_3 - CH_3$$
Ethane

$$CH = CH + 2H_2 \xrightarrow{\text{Ni or Pt or Pd}} CH_3 - CH_3$$
Ethane

(d) Reaction with carbon monoxide: At about 700 K and under high pressure and in presence of a catalyst (ZnO/Cr<sub>2</sub>O<sub>3</sub>), dihydrogen combines with CO to form methanol.

$$CO + 2H_2 \xrightarrow{700 \text{ K}, 200 \text{ atm.}} CH_3OH$$

(e) Hydroformylation of olefins to aldehydes: Olefins combine with carbon monoxide and hydrogen in presence of octacarbonyldicobalt,  $Co_2(CO)_8$ , as catalyst under high temperature and pressure to form aldehydes which can be further reduced to alcohols.

$$\begin{array}{c} \text{R---CH} = \text{CH}_2 + \text{H}_2 + \text{CO} \longrightarrow \text{RCH}_2 - \text{CH}_2 - \text{CHO} \\ \text{Olefin} & \xrightarrow{\text{H}_2} \text{RCH}_2 - \text{CH}_2 - \text{CH}_2 \text{OH} \\ & \xrightarrow{\text{Algebral}} \end{array}$$

# 5 INDUSTRIAL APPLICATIONS

Very large quantities of hydrogen are required for synthesis of a number of products.

(a) Synthesis of ammonia: A mixture of  $N_2$  and  $H_2$  in ratio of 1:3 is compressed to 200 atmospheres and passed over heated catalyst at 500°C. About 8% NH<sub>3</sub> is formed. It is known as **Haber's process**.

$$N_2 + 3H_2 \stackrel{\text{Catalyst}}{\underbrace{\sim}} 2NH_3; \qquad \Delta H = -22.4 \text{ kcal mol}^{-1}$$

Catalyst—Freshly reduced iron having Mo as promoter.

(b) Manufacture of methyl alcohol: Water gas enriched with H<sub>2</sub> is compressed to 200 atmospheres and then passed over catalyst ZnO and CrO<sub>3</sub>, when CH<sub>3</sub>OH is formed.

$$CO + 2H_2 \xrightarrow{\text{Catalyst}} CH_3OH$$

(c) Manufacture of hydrogen chloride: Large quantities of H<sub>2</sub> and Cl<sub>2</sub> obtained as byproducts during manufacture

of NaOH are made to combine to form HCl by burning one in the other.

$$H_2 + Cl_2 \longrightarrow 2HCl$$
 (absorbed in water)

- (d) In food processing industry by hydrogenation of oils: Hydrogen is chiefly used in catalytic hydrogenation of unsaturated (liquid) oils into solid fats for the production of vegetable ghee.
- **(e) Synthetic petrol:** Petrol substitutes are obtained by subjecting a paste of powdered coal in crude oil to the action of hydrogen under pressure and in presence of a catalyst.
- (f) Oxyhydrogen flame: Oxyhydrogen flame produces a temperature of 2800°C while oxyatomic hydrogen flame produces a temperature of 4000°C. This temperature is required for melting substances having very high melting points such as quartz, platinum, etc., and also for welding purposes.
- **(g)** With helium, it is used for filling balloons employed for atmospheric study.
- **(h)** Hydrogen is used for creating a reducing atmosphere in processes like annealing and deoxidising.
- (i) As fuel for space shuttle's main rocket engine: The density of liquid hydrogen is very low (0.08987 gL<sup>-1</sup>), which is less than one-tenth that of water. This low density makes hydrogen a very light weight but bulky fuel. Hydrogen has the highest specific enthalpy of any known fuel, The low density and highest specific enthalpy of liquid hydrogen makes it a valuable fuel for space mission, so liquid hydrogen storage tank with liquid oxygen is used to power the main rocket engine of space shuttle (Fig. 5.1).

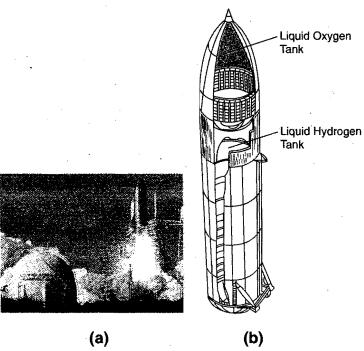

Fig. 5.1 (a) A liquid hydrogen storage tank: Liquid hydrogen is used as a rocket fuel. (b) The arrangement of fuel tanks in the space shuttle

(j) In petrochemical industry: One major use of hydrogen is in the petrochemical industry. In many cases the reaction is one where hydrogen is added to hydrocarbon compound containing carbon-carbon double bonds to produce compound that contain carbon-carbon single bond. For example, 1-butene can be reacted with hydrogen using a platinum or palladium catalyst to produce butane.

$$CH_3CH_2CH = CH_2 + H_2 \xrightarrow{Pt} CH_3CH_2CH_2CH_3$$
Butane
Butane

Butane is the constituent of petrol.

# 5.6.1

#### HYDROGEN ECONOMY

(Use of hydrogen as a fuel)

The world's fossil fuel reserves are being depleted at an alarmingly fast rate. Faced with this dilemma, scientists have made intensive efforts in recent years to develop alternative sources of energy. Hydrogen has been considered as one of the alternate source of energy.

One major advantage of using hydrogen as a fuel is that it is environmentally clean, giving only water as a combustion product. If hydrogen is burned in air, small amount of nitrogen oxides can be produced because of high temperature combination of nitrogen and oxygen, but the combustion products are free from CO, CO<sub>2</sub>, SO<sub>2</sub>, unburned hydrocarbons and other environmental pollutants that result from the combustion of petroleum fuels.

The second advantage with hydrogen is that the heat of combustion of hydrogen per gram is higher than any other fuel as tabulated below:

$$H_2(g) + (\frac{1}{2})O_2(g) \longrightarrow H_2O(l)$$
;  $\Delta H^{\circ} = -284 \text{ kJ mol}^{-1}$ 

#### Energy released by combustion of some substances

Substance	Energy released (kJ/g)
Hydrogen [combustion product H <sub>2</sub> O(l)]	142
Gasoline	48
Crude petroleum	43
Typical animal fat	38.
Coal	29.3
Charcoal	29
Paper	20
Wood or dung	. 15

There has been much talk of the **hydrogen economy.** The idea is that hydrogen could replace coal and oil as major sources of energy. Our energy needs can be met by gaseous, liquid and solid hydrogen. For heating homes, gaseous hydrogen could be conveyed through underground pipes, while liquid hydrogen could be shipped by truck or rail in large vacuum insulated tanks. Automobiles might be powered by solid hydrogen in the form of solid interstitial hydrides. Prototype cars have already been built with their engines modified to run on hydrogen.

#### Hydrogen-oxygen fuel cell

There is a safer way to combine H<sub>2</sub> and O<sub>2</sub> to form water and extract energy in the form of electricity. The device is termed as a hydrogen-oxygen fuel cell (Fig. 5.2). A hydrogenoxygen fuel cell is a galvanic cell in which one of the reactants is a traditional fuel such as hydrogen. In a fuel cell, the chemical energy of a fuel is converted directly into electricity without burning the fuel. Such a cell was invented in 1839 by William Grove but it remained a mere curiosity until the advent of a U.S. programme in 1960. A fuel cell is used as a source of electrical energy in the space vehicles.It differs from an ordinary battery that the reactants are not contained within the cell but instead are continuously supplied from an external reservoir.

The fuel cell contains porous carbon electrodes impregnated with metal catalysts usually platinum and an electrolyte consisting of hot (200°C) aqueous KOH or molten Na<sub>2</sub>CO<sub>3</sub>. Proton Exchange Membrane (PEM) is used for this purpose now-a-days. The fuel (gaseous H<sub>2</sub>) and the oxidising agent (gaseous O<sub>2</sub>) do not react directly but instead flow into separate cell compartments where gaseous hydrogen is oxidised at anode and O<sub>2</sub> is reduced at the cathode. The overall cell reaction is simply the conversion of hydrogen and oxygen to water.

At the anode, hydrogen gas enters a chamber where a porous platinum catalyst oxidizes the hydrogen to  $H^{\dagger}(aq)$  ions at the anode. The hydrogen ions (H<sup>+</sup>) then migrate through a special proton exchange membrane (PEM), which works as an electrolyte and move to the cathode.

$$2H_2(g) \xrightarrow{Pt} 4H^+(aq) + 4e^- \dots$$
 (anode)

The proton exchange membrane allows a very small quantity of  $H^{+}(aq)$  ions for the passage from the anode to the cathode.

At cathode oxygen gas enters the cell, where it comes in contact with a platinum catalyst that facilitates the reduction of  $O_2(g)$  in the presence of  $H^{\dagger}(aq)$  and the electrons produced at anode from oxidation reactions and produce water.

$$O_2(g) + 4H^+(aq) + 4e^- \xrightarrow{\text{Pt}} 2H_2O(l)$$
 ...... (cathode)

Cathode

Cathode

H<sub>2</sub> gas in

Pt(catalyst)

Proton exchange membrane (PEM)

Fig. 5.2 A hydrogen-oxygen fuel cell

→ H<sub>2</sub> gas + water

vapour out

O<sub>2</sub> out ◀

Thus, there is a transfer of electrons—from  $H_2$  to  $O_2$ . The above equation is clearly the equation for the burning of hydrogen in oxygen but in this cell, it is burning without a flame and with relatively little heat. Water is the only product besides a transfer of electrons, which is what we call electricity. Hence, fuel cells are a more environmentally friendly way to produce electricity.

Fuel cells provide electricity and pure water during space flights. Fuel cells are very efficient, converting about 75% of bond energy of fuel into electricity. In contrast, an electric power plant converts 40% of bond energy of coal into electricity. However, fuel cells cannot store electrical energy. They only operate with the continuous flow of reactants. The electrode materials are short lived and expensive.

A major advantage of the fuel cell is that there is no electrode material to be replaced as there is in an ordinary battery. The fuel can be fed in continuously to produce power. In fact, hydrogen-oxygen fuel cells were used in the Gemini and-Apollo missions in the second half of the twentieth century and other space programmes.

Because of cost, large scale applications of fuel cells have been limited. The use of fuel cells is still in its infancy but will surely grow.

#### 5.7 HYDRIDES

Binary compounds of the various elements with hydrogen, in which hydrogen has usually an oxidation number of -1 are called binary hydrides. The type of hydride which an element forms depends upon its electronegativity and hence on the type of bond formed. Hydrides are conveniently studied under three classes.

- (A) Ionic or Saline or Salt like hydrides
- (B) Covalent or molecular hydrides
- (C) Metallic or interstitial hydrides

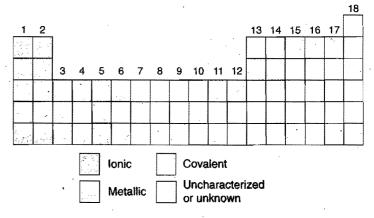

Fig. 5.3 The different classes of binary hydrogen compounds and their distribution in the periodic table

# (A) Ionic or Saline or Salt Like Hydrides

The saline hydrides are compounds of hydrogen with a strongly electropositive metals, i.e., alkali and alkaline earth metals and some highly positive members of lanthanide series with the exception of Be\* and Mg\* which can transfer electrons easily to hydrogen atoms.

These hydrides are generally prepared by heating the metal with hydrogen under pressure at temperatures between  $150^{\circ}$  to  $600^{\circ}$ C.

$$2\text{Li} + \text{H}_2 \xrightarrow{600^{\circ}\text{C}} 2\text{LiH}$$

 $H_2 + 2Na$ , K, Rb or Cs  $\xrightarrow{400^{\circ}\text{C}} 2NaH$ , 2KH, 2RbH or 2CsH

$$H_2$$
 + Ca, Sr or Ba $\xrightarrow{150-300^{\circ}C}$  Ca $H_2$ , Sr $H_2$  or Ba $H_2$ 

#### **■** Properties

(i) They are colourless or greyish coloured crystalline solids. Alkali metal hydrides have **rock-salt structure** (Fig. 5.4). They are non-conducting substances. They consist of ions and behave as salts and thereby called as **ionic hydrides**.

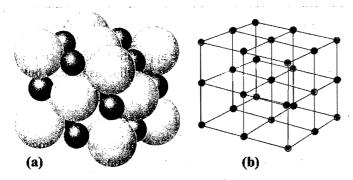

Fig. 5.4 The arrangement of ions in the rock-salt structure.

(a) The unit cell, showing the packing of the individual ions.

(b) In line diagram the red spheres are cations and the blue spheres are anions.

- (ii) They have high melting and boiling points.
- (iii) They conduct electricity in molten state (fused state) liberating hydrogen at anode. This confirms the presence of hydride (H) ions in them. For example molten LiH undergoes electrolysis.

$$LiH \xrightarrow{Li^{+}} Li^{+} + H^{-}$$
Cathode Anode
$$Li^{+} + e \longrightarrow Li \qquad 2H^{-} \longrightarrow H_{2} + 2e$$

(iv) Ionic hydrides can undergo an oxidation-reduction reaction with water to produce hydrogen and a basic solution.

$$LiH(s) + H_2O(l) \longrightarrow H_2(g) + LiOH(aq)$$

For this very reason, these hydrides can be used as a source of hydrogen gas where transportation of  $H_2(g)$  is impractical, such as for inflating weather balloons.

- (v) They have high heats of formation.
- (vi) The density of ionic hydrides is higher than those of

metals from which they are formed. This is because that H<sup>-</sup>ions occupy holes in the lattice of metal.

(vii)The stability of the hydrides decreases as the size of the cation increases.

$$LiH > NaH > KH > RbH > CsH$$
  
 $CaH_2 > SrH_2 > BaH_2$ 

Hydride	Dissociation temp. (K)	Hydride	Dissociation temp. (K)	
LiH	823	CsH	443	
NaH	483	CaH <sub>2</sub>	1158	
KH	473	SrH <sub>2</sub>	. 858	
RbH	443	$BaH_2$	503	

(viii) They burn in air on strong heating due to their decomposition into metal and hydrogen. Both readily combine with oxygen.

$$\begin{array}{cccc}
MH_2 & \longrightarrow M & + & H_2 \\
& \downarrow o_2 & & \downarrow o_2 \\
MO & & H_2O
\end{array}$$

(ix) These hydrides readily react with  $H_2O$ ,  $C_2H_5OH$ ,  $CO_2$ ,  $SO_2$ , dil. acids,  $NH_3$ , etc.

$$\begin{array}{c} \text{LiH} + \text{H}_2\text{O} \longrightarrow \text{LiOH} + \text{H}_2\uparrow\\ \text{LiH} + \text{C}_2\text{H}_5\text{OH} \longrightarrow \text{C}_2\text{H}_5\text{OLi} + \text{H}_2\uparrow\\ \text{LiH} + \text{CO}_2 \longrightarrow \text{HCOOLi}\\ \text{Lithium formate} \\ 2\text{LiH} + 2\text{SO}_2 \longrightarrow \text{Li}_2\text{S}_2\text{O}_4 + \text{H}_2\uparrow\\ \text{Lithium}\\ \text{sulphosulphite} \\ \text{LiH} + \text{NH}_3 \longrightarrow \text{LiNH}_2 + \text{H}_2\uparrow\\ \text{LiH} + \text{HCl} \longrightarrow \text{LiCl} + \text{H}_2\uparrow \end{array}$$

(x) Alkaline earth metal hydrides and LiH combine with nitrogen when heated in its atmosphere.

$$6LiH + N_2 \longrightarrow 2Li_3N + 3H_2 \uparrow$$

$$3CaH_2 + N_2 \longrightarrow Ca_3N_2 + 3H_2 \uparrow$$

(xi) Ionic hydrides show reducing properties.

$$2CO + NaH \longrightarrow HCOONa + C$$
  
 $SiCl_4 + 4NaH \longrightarrow SiH_4 + 4NaCl$   
 $PbSO_4 + 4NaH \longrightarrow PbS + 4NaOH$   
 $Fe_3O_4 + NaH \longrightarrow 3Fe + 4NaOH$ 

(xii) LiH and NaH have been used for preparing valuable reducing agents, e.g., LiAlH<sub>4</sub> (lithium aluminium hydride) and NaBH<sub>4</sub> (sodium borohydride) by the following reactions:

$$4\text{LiH} + \text{AlCl}_3 \xrightarrow{\text{Ether}} \text{LiAlH}_4 + 3\text{LiCl}$$
  
 $\text{B}_2\text{H}_6 + 2\text{NaH} \longrightarrow 2\text{NaBH}_4$ 

**Uses:** Ionic hydrides are used as reducing agents (a source of electrons during chemical reactions), as solid fuels and for ready synthesis of hydrogen via hydrolysis.

<sup>\*</sup>MgH<sub>2</sub> and BeH<sub>2</sub> show significant covalent nature.

**Note:** Binary molecular compounds of hydrogen are often called molecular hydrides, but they are not strictly hydrides as the oxidation number of hydrogen is +1 as in hydracids of halogens, oxygen, nitrogen, etc.

#### (B) Covalent or Molecular Hydrides\*

Covalent hydrides are molecular compounds in which hydrogen is covalently bonded to another element. For example some covalent hydrides are NH<sub>3</sub>, H<sub>2</sub>O, H<sub>2</sub>O<sub>2</sub> and HF. These hydrides are formed by all the true nonmetals (except zero group elements) and the elements like Al, Ga, Sn, Pb, Sb, Bi, Po, etc., which are normally metallic in nature, *i.e.*, this class includes the hydrides of p-block elements. Except third group elements, each other element forms a simple mononuclear hydride of the formula,  $MH_{8-x}$  where x is the number of electrons present in the outermost orbit of the element M. The simplest hydride of B and Ga are dimeric materials, B<sub>2</sub>H<sub>6</sub> (diborane) and Ga<sub>2</sub>H<sub>6</sub> respectively and the hydride of aluminium is polymeric in nature, (AlH<sub>3</sub>)<sub>n</sub>. In addition to mononuclear hydrides, the elements like Si, Ge, N, P, O, S, B, etc., form polynuclear hydrides.

Molecular hydrides are further classified according to their relative numbers of electrons and bonds in their Lewis structures.

- (i) Electron deficient molecular hydrides: These have too few electrons for writing its conventional Lewis structure. Diborane (B<sub>2</sub>H<sub>6</sub>) is an example of this type.
- (ii) Electron-precise molecular hydrides: These are formed by elements of group 14. The molecules are tetrahedral. Methane  $(CH_4)$  is an example of this type.
- (iii) Electron-rich molecular hydrides: The excess electrons are present as lone pairs. The examples are NH<sub>3</sub>, H<sub>2</sub>O, HF, etc. The hydrides NH<sub>3</sub>, H<sub>2</sub>O and HF due to the presence of highly electronegative atoms possess hydrogen bonding also.

These hydrides can be obtained by direct combination of elements or by hydrolysis of compounds such as borides, silicides, phosphides, sulphides, carbides, etc., or by use of LiAlH<sub>4</sub>.

$$N_2 + 3H_2 \longrightarrow 2NH_3$$
 $X_2 + H_2 \longrightarrow 2HX$ 
 $Mg_3B_2 + HCl(dil.) \longrightarrow A$  mixture of boron hydrides

 $Mg_2Si + HCl(dil.) \longrightarrow A$  mixture of silicon hydrides

 $Al_4C_3 + 12H_2O \longrightarrow 4Al(OH)_3 + 3CH_4$ 
 $CaC_2 + 2H_2O \longrightarrow Ca(OH)_2 + C_2H_2$ 
 $Mg_3N_2 + 6H_2O \longrightarrow 3Mg(OH)_2 + 2NH_3$ 
 $FeS + 2HCl(dil.) \longrightarrow FeCl_2 + H_2S$ 
 $Ca_3P_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2PH_3$ 
 $SiCl_4 + LiAlH_4 \xrightarrow{Ether} SiH_4 + LiCl + AlCl_3$ 
 $4BCl_3 + 3LiAlH_4 \xrightarrow{Ether} 2B_2H_6 + 3AlCl_3 + 3LiCl$ 
 $GeCl_4 + LiAlH_4 \xrightarrow{Ether} LiCl + AlCl_3 + GeH_4$ 

Some of these molecular compounds can be prepared by protonation, or proton transfer from an acid to a base, such as  $S^{2-}$ 

$$FeS(s) + 2HCl(aq) \longrightarrow FeCl_2(aq) + H_2S(g)$$

Some of these compounds can be formed from the direct reaction of the elements with hydrogen. If the nonmetal reacting with hydrogen is reactive, the reaction will readily occur without the need for elevated temperatures or a catalyst.

$$F_2(g) + H_2(g) \longrightarrow 2HF(g)$$

The reaction of hydrogen with oxygen to form water is an example of a reaction that requires the input of energy to get started. However, once it does, the reaction is rapid and exothermic.

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(g) \Delta H = -484 \text{ kJ}$$

Because it is such an exothermic reaction and the product is a gas, it is an ideal rocket fuel.

#### **■** Properties

- (i) In these hydrides, hydrogen atoms are covalently bonded to the central atom. The hydrides consist of discrete covalent molecules held together by weak van der Waals' forces and in some cases by hydrogen bonds. As a result, these hydrides are gases, liquids and in few cases solids of low melting and boiling points.
  - (ii) In general, these hydrides are volatile in nature.
  - (iii) They have low electrical conductivity.
- (iv) The thermal stability in a group decreases as the electronegativity decreases with an increase in size of the central atom. The thermal stability decreases in VA or 15th group hydrides.

$$NH_3 > PH_3 > AsH_3 > SbH_3 > BiH_3$$

(v) Covalent hydrides with one or more lone pairs of electrons behave as Lewis bases. Along any given period of periodic table, these hydrides become increasingly acidic as we move from left to right.

$$hinspace{:} ext{NH}_3$$
 ,  $ext{H}_2 ext{O}$  ,  $ext{HF}$  Basic Neutral Acidic

(vi) The hydrides of third group or 13th group are electron deficient and hence behave as Lewis acids.

$$B_2H_6 + 2NH_3 \longrightarrow 2[BH_3 \cdot NH_3]$$

(vii) Some hydrides act as reducing agents.

$$4AgNO_3 + SiH_4 \longrightarrow 4Ag + Si + 4HNO_3$$

(viii) The lighter elements of groups 14, 15 and 16 form polynuclear hydrides. For example, C<sub>2</sub>H<sub>6</sub>, C<sub>3</sub>H<sub>8</sub>, C<sub>4</sub>H<sub>10</sub>, etc. for carbon; Si<sub>2</sub>H<sub>6</sub>, Si<sub>3</sub>H<sub>8</sub>, Si<sub>4</sub>H<sub>10</sub>, etc. for silicon; N<sub>2</sub>H<sub>4</sub>, N<sub>3</sub>H for nitrogen; H<sub>2</sub>O<sub>2</sub>, H<sub>2</sub>O<sub>3</sub> for oxygen.

<sup>\*</sup>The systematic names of covalent or molecular hydrides are usually derived from the name of the element and suffix -ane as:  $PH_3$  Phosphane  $H_2O$  Oxidane  $NH_3$  Azane

**Uses:** Molecular hydrides have wider applications. Some of them are mentioned here. Boron hydrides are used as high energy fuels and propellants. Ammonia is the source for hydrogen at any destination. Phosphine is used for making Holme's signals. H<sub>2</sub>S is an important laboratory reagent. HF is used for etching of glass.

#### (C) Metallic or Interstitial Hydrides

Metallic hydrides are compounds containing a transition metal and hydrogen. Commonly, the formula of these compounds is  $MH_x$ , where x is often not an integer. The **metallic** hydrides are so called because they are electrically conducting.

Many transition and inner transition metals of *d*-block form black powdery, metallic or interstitial hydrides on reacting with hydrogen. However, the metals of groups 7, 8 and 9 do not form hydrides at all. Even from group 6, only chromium forms hydride (CrH). This region of periodic table from group 6 to 9 is referred to as the **hydride gap.** Metallic hydrides of groups 3, 4 and 5 are common. The elements of groups 10, 11, 12 and *f*-block elements (Ce, Eu, Yb, Th, U, etc.) on heating with H<sub>2</sub> under pressure form hydrides.

Earlier it was thought that in these compounds, hydrogen occupies **interstices** (Fig. 5.5) in the metal lattice producing distortion without any change in the metal itself. Consequently, they were termed as **interstitial hydrides**. However, recent studies have shown that except for hydrides of Ni, Pd, Ce and Ac, other hydrides have lattice different from that of the parent metal.

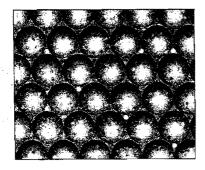

Fig. 5.5 In a metallic hydride, the small hydrogen atoms (the small grey spheres) occupy gaps-called interstices-between the larger metal atoms (the large grey spheres)

These hydrides are prepared by adsorbing hydrogen directly at appropriate temperatures by metals. In some cases, the metals are used as cathodes in the electrolysis of aqueous solutions so that hydrogen evolved at cathode is adsorbed.

The composition of these hydrides may not correspond to simple whole number ratio and therefore, they are called **non-stoichiometric hydrides.** Their composition varies with the conditions of temperature and pressure.

This shows that hydrogen atoms occupy some and not all the interstitial sites in the metallic lattice. Often hydrogen atoms enter the holes in nonstoichiometric amounts. The result is that the composition of the metallic hydride is variable. For example under one pressure of  $H_2$  the composition of the metallic  $MH_x$  might be  $MH_{0.4}$ , whereas at a higher pressure of  $H_2$ , it might be  $MH_{0.5}$ . One way to think about these compounds is to consider the metal crystal to be similar to an apartment building with the lattice holes representing the individual apartments. The occupancy of an apartment building is not fixed; it is instead a function of factors like the rent, conditions of the building and so on.

Some important examples of metallic hydrides are:  $ScH_2$ ,  $YH_2$ ,  $YH_3$ ,  $LaH_2$ ,  $LaH_3$ ,  $TiH_2$ ,  $ZrH_2$ ,  $HfH_2$ , VH,  $VH_2$ , NbH,  $NbH_2$ , TaH, CrH, etc. Some examples of non-stoichiometric hydrides are:  $PdH_{(0.6-0.8)}$ ,  $NbH_{0.11}$ ,  $ZrH_{(1.30-1.9)}$ ,  $TiH_{(1.7-2)}$ ,  $ClH_{2.7}$ ,  $La_{2.8}$ , etc.

#### Properties

- (i) They are black powdery, hard, have a metallic lustre and magnetic properties.
- (ii) They are good conductors of electricity, the conductivity, however, decreases with increase in temperature.
- (iii) The density of these hydrides is lower than those of metals from which they are formed since the crystal lattice expands due to absorption of H<sub>2</sub>.
  - (iv) They have high thermal conductivity.
- (v) They generally undergo reversible decomposition into  $H_2$  gas and metal.

$$\begin{array}{c} \text{Red hot metal} + \text{H}_2 & \xrightarrow{\text{Cool}} & \text{Interstitial} \\ & \text{hydride} \\ & & \text{Strong} \\ & \text{heating} \\ & & \text{Metal} + \text{H}_2 \\ \end{array}$$

**Uses:** (i) Metal hydrides formed as a result of occlusion can be used as hydrogen storage media.

- (ii) Metallic hydrides are widely used in catalytic reduction and hydrogenation for preparing large number of useful compounds.
- (iii) Since the metallic hydrides release their hydrogen (as H<sub>2</sub>) when heated or treated with acid, they are also being investigated for storing and transporting hydrogen. Both saline and metallic hydrides have the high enthalpy densities desirable in a portable fuel.

## (d) Polymeric and Complex hydrides

Besides ionic, covalent and metallic hydrides, there are two more types of hydrides which are called as **polymeric** and **complex hydrides.** 

**Polymeric hydrides:** These are formed by elements having electronegativity in the range of 1.4 - 2.0. These are generally solids. Examples are:  $(BeH_2)_n$ ,  $(MgH_2)_n$ ,  $(AlH_3)_n$ ,  $(InH_3)_n$ ,  $(SiH_4)_n$ , etc. These hydrides consist of molecules

held together in two or three-dimensions by hydrogen bridges (Three-centre-two electron bonds.)

**Complex hydrides:** These are the compounds which contain hydride ions (H<sup>-</sup>) coordinated to metal atom. Examples are: LiAlH<sub>4</sub>, LiBH<sub>4</sub>, NaBH<sub>4</sub>, etc.

# 5.8 SPECIAL FORMS OF HYDROGEN

## (a) Nascent Hydrogen

hydrogen at the moment of formation is known as **nascent** hydrogen. It is more active than ordinary hydrogen. For example, when ordinary hydrogen is passed through acidified potassium permanganate solution or ferric chloride solution, neither of them is reduced. However, when zinc pieces are added, both get reduced.

Ordinary 
$$\longrightarrow$$
 KMnO<sub>4</sub>/H<sub>2</sub>SO<sub>4</sub>  $\longrightarrow$  No change in colour as hydrogen

Purple coloured reduction does not occur solution

 $+$  Zn pieces

 $(Zn+dil. H_2SO_4 \rightarrow Hydrogen liberated)$ 

Decolourisation occurs, *i.e.*, liberated hydrogen reduces acidified KMnO<sub>4</sub>

It is believed that a part of energy liberated in the reaction producing hydrogen become associated with hydrogen molecules and thus make them hyper active.

# (b) Atomic Hydrogen

When hydrogen is passed through an electric arc established between two tungsten filaments, hydrogen is dissociated into atoms. This form of hydrogen is known as atomic hydrogen.

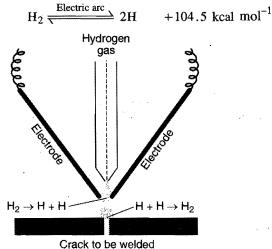

Fig. 5.6 Atomic hydrogen welding torch

The life period of atomic hydrogen is 0.3 second. It readily returns to ordinary form. This conversion is highly exothermic and used for welding purposes. This form of hydrogen is more active than ordinary hydrogen.

**Note:** (i) Atomic hydrogen can be produced at very high temperatures but nascent hydrogen is formed even at ordinary temperature.

(ii) The reducing power of atomic hydrogen is more than nascent hydrogen.

## 🤏 (c) Ortho and Para Hydrogen

Hydrogen molecule is diatomic, *i.e.*, it contains two hydrogen atoms. Each atom has one proton in the nucleus with an electron moving around it. Like electron, the proton is also spinning about an axis. Two protons in the hydrogen molecule may have either their spins in the same direction or in opposite directions giving rise to two forms **ortho** and **para**. When the proton spins are in the same direction, the form is termed as **ortho hydrogen** and when the proton spins are in the opposite directions, the form is known as **para hydrogen**.

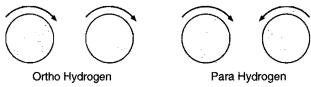

Fig. 5.7 Ortho and para hydrogen

Ordinary hydrogen is a mixture of these two forms. Ordinary hydrogen consists of 75% ortho and 25% para under ordinary atmospheric conditions. At very low temperature say about 20 K, 99.82% para and only 0.18% ortho is present but as the temperature rises, the percentage of ortho form increases while that of para form decreases reaching to a limiting ratio 75% ortho and 25% para under ordinary atmospheric conditions. This shows that intrinsic energy of ortho form is higher than para form.

The two forms differ in their physical properties like specific heat, thermal conductivity, boiling point, etc., but show similar chemical properties. Ortho form is more stable than para form. Pure para form can be obtained at low temperature (20 K) but pure ortho form is very difficult to obtain.

# 5.9 ISOTOPES OF HYDROGEN

There are three known isotopes of hydrogen, each possessing an atomic number 1 and atomic masses 1, 2 and 3 respectively, these are named as **protium**, **deuterium** and **tritium**.

- (a) The most common is the ordinary hydrogen usually called **protium** with atomic mass 1.008123. It consists of one proton in the nucleus and an electron revolving around it. This isotope constitutes 99.984 per cent of the total hydrogen available in nature. It is represented as <sup>1</sup><sub>1</sub>H.
- (b) The second isotope of hydrogen is called heavy hydrogen or deuterium. It consists of one proton and one neutron in the nucleus and an electron revolving around it. Its

atomic mass is 2.0142. It constitutes only 0.016 per cent of the total hydrogen occurring in nature. It is represented by the symbol D or <sup>2</sup>H.

(c) The third isotope of hydrogen is called **tritium.** It consists of one proton and two neutrons in the nucleus and an electron revolving around it. Its atomic mass is 3.0170. It constitutes  $1 \times 10^{-15}$  per cent of the total natural hydrogen. Unlike the above two isotopes, this isotope is unstable and shows radioactivity. It is represented by the symbol T or  ${}_{1}^{3}H$ .

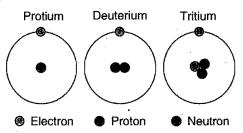

Fig. 5.8 Isotopes of hydrogen

The three isotopes have same chemical properties as they have same electronic configuration  $1s^1$ . Their physical properties are, however, different due to differences in their atomic masses. The atomic structures of three isotopes are shown in Fig. 5.8. Owing to different masses, the rates with which the three isotopes react are different. This type of difference in properties due to difference in atomic masses is called **isotopic effect.** 

Since, the percentages of deuterium and tritium present in natural hydrogen are very small, the properties of ordinarily hydrogen are mainly due to protium. Some of the important points regarding the three isotopes are tabulated below:

Property	Protium or ordinary hydrogen	Deuterium or heavy hydrogen	Tritium
Atomic number	1	1	1 .
Mass number	1 .	2	3
Exact atomic mass	1.008123	2.0142	3.0170
Symbol	iΗ	$^2_1\text{H or }^2_1\text{D}$	$^3_1$ H or $^3_1$ T

#### HEAVY HYDROGEN OR DEUTERIUM

## Preparation

There are two sources from which deuterium can be obtained (i) Ordinary hydrogen, (ii) Heavy water.

## (i) Separation from ordinary hydrogen:

- (a) From liquid hydrogen: Deuterium was obtained by Urey and his co-workers by the evaporation of liquid hydrogen near its triple point 13.9 K under reduced pressure. 4 litres of liquid hydrogen are concentrated to 1 mL. The resulting liquid is found to be rich in deuterium.
- **(b) By diffusion:** Deuterium can be separated from ordinary hydrogen by the application of diffusion method. Protium being lighter diffuses more readily than deuterium. The diffusion is carried out under reduced pressure. This method is slow and tedious but produces pure deuterium.
- **(c) By adsorption on charcoal:** It is observed that protium, the lighter isotope, is adsorbed more readily and more strongly on charcoal. Thus, the ordinary hydrogen is passed over charcoal kept at liquid air temperature, most of the lighter isotope gets adsorbed and the fraction richer in deuterium passes out unchanged.

#### (ii) Preparation from heavy water

Ordinary water contains about one part of heavy water in 6000 parts of ordinary water. Heavy water is obtained from ordinary water by continuous electrolysis method in which 20 litres of water reduced to 1 mL. Now-a-days, heavy water is the important source of deuterium. The following methods can be used for the preparation of deuterium from heavy water. These methods can be even used in laboratory.

(a) By action of sodium: A pure sample of deuterium is obtained by the action of sodium on heavy water.

**(b)** By using red hot iron or tungsten: Gaseous deuterium may be prepared by decomposing heavy water with red hot iron or heated tungsten,

$$4D_2O(\text{vapours}) + 3Fe \text{ (red hot)} = Fe_3O_4 + 4D_2$$
  
 $3D_2O + W \xrightarrow{1000^{\circ}C} WO_3 + 3D_2$   
Vapours Heated electrically

The WO<sub>3</sub> formed distills over at the working temperature, exposing a fresh surface for further oxidation.

**(c) By electrolysis:** The solution of sodium carbonate (anhydrous) in heavy water on electrolysis between nickel electrodes yield deuterium on cathode.

$$2D_2O \xrightarrow{\text{Electrolysis}} 2D_2 + O_2$$

#### **Properties of Deuterium**

(a) Physical Properties: (i) It is a colourless, odourless and tasteless gas. It is insoluble in water. (ii) It is bad conductor of heat and electricity. (iii) Its density is twice that of ordinary hydrogen. The density at NTP is 0.18 g/lit.

(iv) The atomicity like ordinary hydrogen is 2 and its molecule is diatomic  $(D_2)$ . (v) The various physical constants are tabulated below:

Property	Deuterium 'D <sub>2</sub> '	'H <sub>2</sub> ' Hydrogen or protium
1 Boiling point (°C)	-249.5	-252.6
2. Melting point (°C)	-254.5	-259.1
3. Latent heat of fusion (cal/mole)	52.3	28.0
<ol> <li>Latent heat of vaporisation (cal/mole)</li> </ol>	293.0	216.0
5. Dissociation energy (kcal/mole)	104.5	102.5
6. Density at NTP (g/L)	0.18	0.09

The physical constants of deuterium are somewhat higher than protium.

- (vi) The deuterium molecule, like hydrogen, also exists in ortho and para forms. At ordinary temperature, it is a mixture of 2 parts of ortho and 1 part of para.
- **(b) Chemical Properties:** Chemically deuterium is similar to ordinary hydrogen. It enters all the reactions characteristic of the ordinary hydrogen and forms completely equivalent compounds. However, it reacts slowly and less completely than ordinary hydrogen due to heaviness.
- (i) **Burning:** Like hydrogen, it burns in air or oxygen, forming deuterium oxide,  $D_2O$  (heavy water),

$$2D_2 + O_2 \xrightarrow{560^{\circ}C} 2D_2O$$

(ii) Action with halogens: It reacts with halogens under suitable conditions to form deuterium halides which are similar to the halogen hydracids.

(iii) Combination with nitrogen: Deuterium combines with nitrogen in the presence of a catalyst to form heavy ammonia.

$$3D_2 + N_2 \xrightarrow{Catalyst} 2ND_3$$
Deutero ammonia

- (iv) Deuterium is occluded by metallic surfaces more slowly than hydrogen.
- (v) Action with unsaturated hydrocarbons: Deuterium reacts more slowly with unsaturated hydrocarbons in presence of a catalyst.

$$\begin{array}{c|c} CH_2 & CH_2D \\ \parallel & + D_2 & \xrightarrow{Ni} & \parallel \\ CH_2 & CH_2D \\ \text{Ethene} & Deutero etha \\ \end{array}$$

(vi) Action with metals: It combines with alkali and alkaline earth metals at higher temperatures. The compounds are similar to corresponding hydrides.

$$\begin{array}{ccc} 2Na + D_2 & \xrightarrow{360^{\circ}C} & 2NaD \\ & & \text{Sodium deuteride} \\ Ca + D_2 & \longrightarrow & CaD_2 \end{array}$$

(vii) Exch reactions: In a number of reactions, deuterium occupies the place of hydrogen in an ion or a molecule. The exchange reactions usually occur in presence of a catalyst like platinum black, finely divided nickel, palladium, etc.

$$\begin{array}{c} H_2O + D_2 \xrightarrow{Pt} D_2O + H_2 \\ 2NH_3 + 3D_2 \xrightarrow{Ni} 2ND_3 + 3H_2 \\ CH_4 + 2D_2 \xrightarrow{Pt} CD_4 + 2H_2 \\ Deutero \\ H_2 + D_2 \xrightarrow{600^{\circ}C} 2HD \\ Deutero hydrogen \end{array}$$

A number of compounds are known in which ordinary hydrogen has been replaced by heavy hydrogen, e.g., DNO<sub>37</sub>-D<sub>2</sub>SO<sub>4</sub>, D<sub>3</sub>PO<sub>4</sub> and also the organic compounds such as DCN, CH<sub>3</sub>COOD, C<sub>2</sub>D<sub>2</sub>, C<sub>6</sub>D<sub>6</sub>, etc., are formed.

#### Uses

- (i) It has been widely used for the preparation of deutero compounds.
- (ii) Deuterium and its compounds are used as tracers in the study of mechanism of chemical reactions and biological systems.
- (iii) One of the most important use of deuterium is as a bombarding agent in the artificial transmutation of elements.

For Example,

(iv) It is used in fusion reactions, *i.e.*, in hydrogen bombs.  ${}_{1}^{3}H + {}_{1}^{2}H \longrightarrow {}_{2}^{4}He + {}_{0}^{1}n + energy$ 

# 5.1 TRITIUM (3H or 3T)

Tritium is the isotope of hydrogen having mass 3. The existence of this isotope was confirmed by **Bleakney** and **Gould** in 1934, by spectrometric studies on samples rich in deuterium. It occurs in ordinary hydrogen in very minute quantity, *i.e.*,7 parts are present in 10<sup>7</sup> parts of ordinary hydrogen. Its oxide, T<sub>2</sub>O, is present in water in extremely minute traces and, therefore, its recovery either from ordinary hydrogen or ordinary water is not possible. Artificial transmutation reactions or nuclear reactions are used to produce tritium in very small quantities:

(a) Oliphant, Harteck and Rutherford (1934) prepared tritium by bombarding deuterium compounds with high energy deuterons.

$$_{1}^{2}H + _{1}^{2}H \longrightarrow _{1}^{3}H + _{1}^{1}H$$

(b) Tritium is produced by a number of nuclear reactions.

$${}^{9}_{4}\text{Be} + {}^{2}_{1}\text{H} \longrightarrow {}^{8}_{4}\text{Be} + {}^{3}_{1}\text{H}$$

$${}^{11}_{5}\text{B} + {}^{1}_{0}n \longrightarrow {}^{9}_{4}\text{Be} + {}^{3}_{1}\text{H}$$

$${}^{6}_{3}\text{Li} + {}^{1}_{0}n \longrightarrow {}^{4}_{2}\text{He} + {}^{3}_{1}\text{H}$$
(Slow)

This is probably the best nuclear reaction of obtaining tritium.

#### Properties

It is a gas. It boils at  $-248.1^{\circ}$ C and freezes at  $-252.4^{\circ}$ C. It is diatomic in nature. It is radioactive in nature. It undergoes a  $\beta$ -ray change. It's half life period is 12.4 years.

$${}_{1}^{3}T \longrightarrow {}_{2}^{3}He + {}_{-1}^{0}e$$

Chemically it is similar to ordinary hydrogen.

#### **Uses**

It is used in several tracer experiments. It is used in fusion reactions when large amount of energy is released.

$${}_{1}^{3}H + {}_{1}^{2}H \longrightarrow {}_{2}^{4}He + {}_{0}^{1}n + energy$$

## Physical constants of H<sub>2</sub>, D<sub>2</sub> and T<sub>2</sub>

# 5.12 HEAVY WATER OR DEUTERIUM OXIDE (D<sub>2</sub>O)

The credit for the discovery of heavy water goes to **Urey** who first proved that ordinary water contains one part of heavy water in 6000 parts of it. **Lewis** and **Donald**, in 1933, were able to isolate few millilitres of pure D<sub>2</sub>O by continuous electrolysis of water containing alkali.

#### Preparation

Heavy water is prepared by following methods:

(i) By fractional distillation of ordinary water: The boiling points of ordinary water ( $H_2O$ ) and heavy water ( $D_2O$ ) are 100°C and 101.42°C, respectively. Since, the difference in boiling points is very small, the fractional distillation of ordinary water is done in a very long fractionating column (13 metre long) and the process is repeated several times. The lighter

fraction (H<sub>2</sub>O) is distilled first while the heavier fraction (D<sub>2</sub>O) is left behind. The heavier fraction becomes richer in D<sub>2</sub>O.

- (ii) By fractional freezing: The freezing points of ordinary water and heavy water are 0°C and 3.82°C, respectively. Thus, the two materials are separated by fractional freezing. The process is repeated several times.
- (iii) Taylor, Eyring and Frost method: (Multistage electrolysis of ordinary water): Heavy water is mainly prepared by this method these days. The method is based on continuous and prolonged electrolysis of ordinary water containing NaOH.

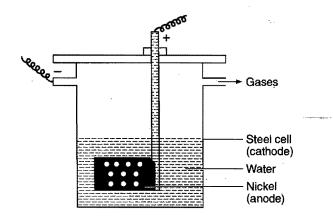

Fig. 5.9 Electrolytic cell for the preparation of heavy water

The cell used in this method is shown in Fig. 5.9. The cell dimensions are 45 cm long and 10 cm in diameter. It is made of steel. The cell itself acts as a cathode while a perforated cylindrical sheet of nickel acts as the anode. The electrolysis is completed in seven stages and in actual practice a number of electrolytic cells are used.

#### Properties of Heavy Water

**Physical Properties:** (a) Heavy water is a colourless, odourless and tasteless mobile liquid, (b) Nearly all the physical constants are higher than the corresponding values of ordinary water. The comparison of physical constants is tabulated below:

Physical Property	H <sub>2</sub> O	$D_2O$
Maximum density (g/mL)	1.00 at 277 K	1.1073 at 284.6 K
Melting point	0°C or 273 K	3.82°C or 276.82 K
Boiling point	100°C or 373K	101.42 or 374.42 K
Specific heat	1.00 cal/g K	1.01 cal/g K
Latent heat of fusion	79.7 cal/g	75.5 cal/g
Latent heat of vaporisation	539 cal/g	557 cal/g
Viscosity at 20°C	10.09 millipoise	12.6 millipoise
Surface tension at 20°C	72.8 dynes/cm	67.8 dynes/cm
Dielectric constant	78.39	78.06
Solubility of NaCl (per lit.)	359 g	305 g
Molecular mass	18.016	20.03
Dissociation constant or ionic	$1.0 \times 10^{-14}$	$0.3 \times 10^{-14}$
product at 25°C	•	,

**Chemical Properties:** Heavy water is chemically similar to ordinary water. However, D<sub>2</sub>O reacts more slowly than H<sub>2</sub>O in chemical reactions.

(a) Action with metals: D<sub>2</sub>O reacts with alkali and alkaline earth metals liberating heavy hydrogen.

$$2D_2O + 2Na \longrightarrow 2NaOD + D_2$$
Sodium
deuteroxide
$$2D_2O + Ca \longrightarrow Ca(OD)_2 + D_2$$
Calcium
deuteroxide

Vapours of heavy water are decomposed by hot metals like Zn, Fe, etc.

$$D_2O + Zn \longrightarrow ZnO + D_2$$
  
 $4D_2O + 3Fe \longrightarrow Fe_3O_4 + 4D_2$   
Magnetic  
ovide

**(b) Action with metallic oxides:** D<sub>2</sub>O reacts slowly with basic oxides to form heavy alkalies.

$$Na_2O + D_2O \longrightarrow 2NaOD$$
  
 $CaO + D_2O \longrightarrow Ca(OD)_2$ 

(c) Action with non-metallic oxides: D<sub>2</sub>O reacts slowly with acidic oxides to form deutero acids.

$$N_2O_5 + D_2O \longrightarrow 2DNO_3$$
Deutero nitric
acid

 $P_2O_5 + 3D_2O \longrightarrow 2D_3PO_4$ 
Deutero
phosphoric acid

 $SO_3 + D_2O \longrightarrow D_2SO_4$ 
Deutero
sulphuric acid

(d) Action with metallic carbides, phosphides, nitrides, arsenides, etc.: Like H<sub>2</sub>O, heavy water reacts with carbides, phosphides, nitrides, arsenides, etc., to form corresponding deutero compounds.

$$\begin{array}{c} CaC_2 + 2D_2O \longrightarrow Ca(OD)_2 + C_2D_2 \\ Deutero \ acctylene \end{array}$$
 
$$Al_4C_3 + 12D_2O \longrightarrow 4Al(OD)_3 + 3CD_4 \\ Deutero \ methane \end{array}$$
 
$$Mg_3N_2 + 6D_2O \longrightarrow 3Mg(OD)_2 + 2ND_3 \\ Deutero \ ammonia \\ AlN + 3D_2O \longrightarrow Al(OD)_3 + ND_3 \\ Deutero \ ammonia \\ Ca_3P_2 + 6D_2O \longrightarrow 3Ca(OD)_2 + 2PD_3 \\ Deutero \ phosphine \\ Na_3As + 3D_2O \longrightarrow 3NaOD + AsD_3 \\ Deutero \ arsine \end{array}$$

(e) Electrolysis: A solution of heavy water containing Na<sub>2</sub>CO<sub>3</sub> when electrolysed evolve heavy hydrogen at cathode.

$$2D_2O \xrightarrow{\text{Electrolysis}} 2D_2 + O_2$$
(Cathode) (Anode)

**(f)** Exchange reactions: When compounds having labile hydrogen react with heavy water, hydrogen is exchanged by deuterium partially or completely.

$$NaOH + D_2O \implies NaOD + HDO$$
 $HCl(aq) + D_2O \implies DCl + HDO$ 
 $NH_4Cl(aq) + 4D_2O \implies ND_4Cl + 4HDO$ 

- (g) **Deutero-hydrates:** Heavy water like ordinary water may be associated with salts as water of crystallisation, giving deutero-hydrate, *e.g.*, Na<sub>2</sub>SO<sub>4</sub>·10D<sub>2</sub>O, CuSO<sub>4</sub>·5D<sub>2</sub>O, MgSO<sub>4</sub>·7D<sub>2</sub>O, etc.
- (h) Deuterolysis: Water brings hydrolysis of certain inorganic salts,  $D_2O$  gives similar reactions which are termed deuterolysis.

(i) Biological and physiological effects: It has been established that heavy water of high concentration retards the growth of plants and animals. It has been confirmed by Lewis that tobacco seeds do not grow in heavy water. Pure heavy water kills small fishes, tadpoles and mice, when fed on with it.

**Taylor** has shown that heavy water has germicide and bactericide properties. Water containing small quantity of  $D_2O$  acts as a tonic and stimulates vegetable growth. Certain moulds have been found to develop better in heavy water in comparison to ordinary water:

## Uses Uses

The following are the important uses of heavy water:

- (i) As a neutron moderator: Fission in uranium-235 is brought by slow speed neutrons. The substances which are used for slowing down the speed of neutrons are called moderators. Heavy water is used for this purpose in nuclear reactors.
- (ii) For the preparation of deuterium: Heavy water on electrolysis or by its decomposition with metals produces deuterium.
- (iii) As a tracer compound: Heavy water is commonly used as a tracer compound for studying various reaction mechanisms. It has also been used for studying the structure of some oxyacids of phosphorus such as H<sub>3</sub>PO<sub>2</sub> and H<sub>3</sub>PO<sub>3</sub> as to determine the number of ionisable hydrogen atoms.

**Production in India:** Various units have been set in India to manufacture heavy water. These are situated at Nangal, Trombay, Rourkela, Namrup and Neyveli.

# **5.13** WATER

Water is one of the most plentiful and readily available of all chemicals. Almost three-fourth of the earth's surface is covered with water. It is essential to life. Two-third of the human body is water. It has special importance to a chemist because of its ability to dissolve so many other substances. As a result, water serves as a medium in which a great variety of chemical reactions occur. Although it is most often perceived as a liquid at normal atmospheric pressure, water exists as a solid below 0°C and as a gas above 100°C. The terms ice and steam are used to describe the solid and gaseous states of water.

#### Properties of Pure Water

(a) Physical Properties: (i) Pure water is colourless, tasteless and odourless. It gives bluish tinge in thick layers. (ii) It freezes at 0°C and boils at 100°C. (iii) Its maximum density is 1.00 gcm<sup>-3</sup> at 4°C. (iv) It is a polar molecule and has V-shaped structure. The bond angle is 104.5°. (v) It has a high dielectric constant. The polar character of water makes it an excellent solvent for polar and ionic substances. (vi) It is a poor conductor of electricity. (vii) It has the tendency to associate. It exists in the liquid state not as a single H<sub>2</sub>O molecule but as associated molecules through hydrogen bonding [Fig. 5.11(b)]. The existence of hydrogen bonding is responsible for high values of specific heat, the latent heat of fusion and latent heat of vaporisation.

#### **Physical Constants of Water**

M.pt./K	273.0
B.pt./K	373.0
Enthalpy of formation/kJ mol <sup>-1</sup>	-285.9
Enthalpy of fusion/kJ mol-1	6.01
Enthalpy of vaporisation/kJ mol <sup>-1</sup>	40.06
Viscosity (centipoise)	0.89
Dielectric constant	78.39
Density (g cm <sup>-3</sup> )	1.00
Temp. of max. density (K)	276.98

**(b) Chemical Properties:** (i) Water is neutral in nature. pH of the pure water is 7. It is a weak electrolyte and feebly ionises into H<sup>+</sup> and OH<sup>-</sup> ions.

$$H_2O \rightleftharpoons H^+ + OH^-$$

In pure water  $[H^+] = [OH^-] = 10^{-7}$  at 25°C.

(ii) It reacts with active metals and evolves hydrogen. The reaction is exothermic in the case of alkali and alkaline earth metals.

$$2Na + 2H_2O \longrightarrow 2NaOH + H_2$$
  
 $Ca + 2H_2O \longrightarrow Ca(OH)_2 + H_2$ 

It is decomposed by metals like Zn, Mg, Fe, etc., when steam is passed over hot metals.

$$Zn + H_2O \longrightarrow ZnO + H_2$$
  
 $3Fe + 4H_2O \longrightarrow Fe_3O_4 + 4H_2$   
 $Mg + 2H_2O \longrightarrow Mg(OH)_2 + H_2$ 

Pb and Cu decompose water only at a white heat. Ag, Au, Hg and Pt metals do not decompose water.

(iii) Reaction with nonmetals: Fluorine decomposes cold water.

$$\begin{array}{ccc} 2F_2 \,+\, 2H_2O \longrightarrow \, 2H_2F_2 \,+\, O_2 \\ \\ 3F_2 \,+\, 3H_2O \longrightarrow \, 3H_2F_2 \,+\, O_3 \end{array} \right\} Ozonised \ oxygen$$

Chlorine decomposes cold water forming HCl and HClO.

$$Cl_2 + H_2O \longrightarrow HCl + HClO$$
Hypochlorous
acid

However, in presence of sunlight only HCl is formed with liberation of oxygen.

$$2Cl_2 + 2H_2O \xrightarrow{\text{Sunlight}} 4HCl + O_2$$

When steam is passed over red hot coke (1000°C), water gas is formed.

$$C + H_2O \longrightarrow \underbrace{CO + H_2}_{\text{Water gas}}$$

(iv) Action on nonmetallic oxides: Acidic oxides combine with water to form acids.

$$CO_2 + H_2O \Longrightarrow H_2CO_3$$
 (Carbonic acid)  
 $SO_2 + H_2O \longrightarrow H_2SO_3$  (Sulphurous acid)  
 $SO_3 + H_2O \longrightarrow H_2SO_4$  (Sulphuric acid)  
 $P_2O_5 + 3H_2O \longrightarrow 2H_3PO_4$  (Orthophosphoric acid)  
 $N_2O_5 + H_2O \longrightarrow 2HNO_3$  (Nitric acid)  
 $Cl_2O_7 + H_2O \longrightarrow 2HClO_4$  (Perchloric acid)

(v) Action on metallic oxides: Basic oxides combine with water to form alkalies.

$$Na_2O + H_2O \longrightarrow 2NaOH$$
  
 $CaO + H_2O \longrightarrow Ca(OH)_2$ 

(vi) Action on hydrides, carbides, nitrides, phosphides: Water decomposes these compounds with liberation of hydrogen, acetylene (or methane), ammonia, phosphine respectively.

$$CaH_2 + 2H_2O \longrightarrow Ca(OH)_2 + 2H_2$$

$$CaC_2 + 2H_2O \longrightarrow Ca(OH)_2 + C_2H_2$$

$$Al_4C_3 + 12H_2O \longrightarrow 4Al(OH)_3 + 3CH_4$$

$$Mg_3N_2 + 6H_2O \longrightarrow 3Mg(OH)_2 + 2NH_3$$

$$Ca_3P_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2PH_3$$

(vii) Hydrolysis: Many salts specially the salts of strong bases with weak acids, weak bases with strong acids and weak bases with weak acids undergo hydrolysis with water.

$$CH_3COONa + H_2O \Longrightarrow CH_3COOH + NaOH$$
  
 $CH_3COONH_4 + H_2O \Longrightarrow CH_3COOH + NH_4OH$   
 $FeSO_4 + 2H_2O \Longrightarrow Fe(OH)_2 + H_2SO_4$ 

Some salts on hydrolysis form oxy compounds.

$$\begin{array}{c} BiCl_3 + H_2O \longrightarrow & BiOCl + 2HCl \\ & Bismuth \\ & oxychloride \\ SbCl_3 + H_2O \longrightarrow & SbOCl + 2HCl \\ & Antimony \\ & oxychloride \\ \end{array}$$

Halides of nonmetals are decomposed by water.

$$PCl_5 + 4H_2O \longrightarrow H_3PO_4 + 5HCl$$
  
 $PCl_3 + 3H_2O \longrightarrow H_3PO_3 + 3HCl$   
 $SO_2Cl_2 + 2H_2O \longrightarrow H_2SO_4 + 2HCl$   
 $SiCl_4 + 3H_2O \longrightarrow H_2SiO_3 + 4HCl$ 

(viii) **Decomposition:** Water containing either alkali or acid when electrolysed gets decomposed into  $H_2$  and  $O_2$ .

$$2H_2O \longrightarrow 2H_2 + O_2$$

When heated at 2500°C, it breaks up into hydrogen and oxygen to a small extent (4%).

(ix) Water of crystallisation: It combines with many salts during crystallisation to form hydrates, e.g.,

The water present in the hydrates is called water of hydration or water of crystallisation.

The hydrates can be classified into the following three categories:

- (a) Water molecules are coordinated to the central metal ion to form complex ions. For example, in chromic chloride hexahydrate, the six molecules are linked to the central  $Cr^{3+}$  ion,  $[Cr(H_2O)_6]Cl_3$ .
- (b) Water molecules are linked to some oxygen containing anions by hydrogen bonding. For example, in  $CuSO_4 \cdot 5H_2O$ , four  $H_2O$  molecules are coordinated to the central  $Cu^{2+}$  ion while the fifth  $H_2O$  molecule is linked to  $SO_4^{2-}$  ion by hydrogen bonding.
- (c) Water molecules are present in interstitial sites or voids in the crystal lattice. For example, in barium chloride dihydrate, BaCl<sub>2</sub>·2H<sub>2</sub>O, the two water moelcules occupy the voids in the crystal lattice.
- (x) Water as a catalyst: Water acts as a catalyst in many reactions. Perfectly dry gases generally do not react but the presence of moisture brings the chemical change. Ammonia and hydrochloric acid gas combine only in presence of moisture.

#### Tests of water

- (i) A drop of water when added to anhydrous copper sulphate, changes its colour from white to blue.
- (ii) Water reacts with CaC<sub>2</sub> to evolve acetylene which burns with bright flame.

#### **Structure of Water Molecule**

Oxygen atom in water molecule is  $sp^3$  hybridized, four hybrid orbitals directed towards the corners of a tetrahedral are formed. Two of the hybrid orbitals having one electron each overlap with two hydrogen atoms and form two sigma bonds. Thus, the molecule has a bent structure with a bond angle of  $104.5^{\circ}$  (Fig. 5.10). The bond angle is less than the expected angle in tetrahedron due to the presence of two lone pairs of electrons on two uncombined hybrid orbitals which repel each other and the bonded pairs cause them to come closer and thereby reducing the bond angle from  $109^{\circ}28'$  to  $104.5^{\circ}$ . Because of high electronegativity of oxygen, the O—H bonds are polar, *i.e.*, oxygen is partially negatively charged and each hydrogen is partially positively charged. The molecule is polar and possesses dipole moment (1.84 D). Molecules are linked with each other by hydrogen bonding [Fig. 5.11 (b)].

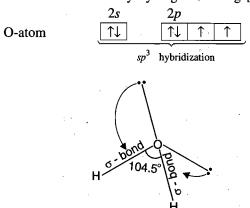

Fig. 5.10

**Example 2.** Explain, why the density of ice is less than water? or why there is decrease in volume when ice melts?

**Solution:** In ice each molecule of H<sub>2</sub>O is surrounded by three H<sub>2</sub>O molecules in hexagonal honey comb manner as shown in Fig. 5.11 (a). On the other hand in water, each molecule is surrounded by four neighbouring molecules randomly [Fig. 5.11 (b)]. This arrangement gives rise to an open-cage like structure. There are evidently, a number of 'holes' or open spaces. In such a structure lesser number of molecules are packed per mL. When ice melts a large number of hydrogen bonds are broken. The molecules, therefore, move into the holes or open spaces and come closer to each other than they were in solid state. This results sharp increase in the density. Thus, ice has lower density than water and there is contraction in volume. The contraction continues from 0°C to

4°C as the hydrogen bonds are broken progressively. The density of water is maximum at 4°C.

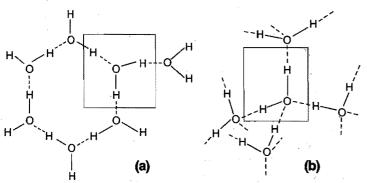

Fig. 5.11 (a) Hexagonal honey comb structure of ice. In ice each molecule of H<sub>2</sub>O is surrounded by three neighbouring H<sub>2</sub>O molecules (b) In water, each H<sub>2</sub>O molecule is surrounded by four neighbouring H<sub>2</sub>O molecules randomly

# 5.14 HARD AND SOFT WATER

A water is said to be the soft if it produces sufficient lather with the soap and water is described as being hard if it forms an insoluble scum before it forms a lather with soap\*. The hardness of natural water is generally caused by presence of the bicarbonates and sulphates of calcium and magnesium but infact all soluble salts that form a scum with soap cause hardness.

$$\operatorname{Ca}^{2+}(aq) + 2\operatorname{C}_{17}\operatorname{H}_{35}\operatorname{COO}^{-}(aq) \longrightarrow (\operatorname{C}_{17}\operatorname{H}_{35}\operatorname{COO})_2\operatorname{Ca}$$

$$\operatorname{Mg}^{2+}(aq) + 2\operatorname{C}_{17}\operatorname{H}_{35}\operatorname{COO}^{-}(aq) \longrightarrow (\operatorname{C}_{17}\operatorname{H}_{35}\operatorname{COO})_2\operatorname{Mg}$$
Anion of soap Insoluble precipitates

Soap will not produce lather with water until all the calcium and magnesium ions have been precipitated. Hard water thus wastes soap. Hardness of water is of two types:

- (a) Temporary hardness
- (b) Permanent hardness.

## (a) Temporary Hardness

This is due to the presence of bicarbonates of calcium and magnesium. Rain water dissolves small quantities of CO<sub>2</sub> from the atmosphere forming a very dilute solution of carbonic acid. This water attacks calcium and magnesium carbonates in any rocks over which it flows and the soluble hydrogen carbonates or bicarbonates are formed.

$$CaCO_3 + H_2O + CO_2 = Ca(HCO_3)_2$$

Temporary hardness in water is easily removed by boiling, as the bicarbonates decompose readily and the insoluble carbonates are precipitated.

$$Ca(HCO_3)_2 \xrightarrow{Boil} CaCO_3 + H_2O + CO_2$$

$$(Insoluble)$$

$$Mg(HCO_3)_2 \xrightarrow{Boil} MgCO_3 + H_2O + CO_2$$

$$(Insoluble)$$

Temporary hardness can also be removed by Clark's process which involves the addition of slaked lime [Ca(OH)<sub>2</sub>].

$$Ca(HCO_3)_2 + Ca(OH)_2 \longrightarrow \underbrace{2CaCO_3 + 2H_2O}_{(Insoluble)}$$

$$Mg(HCO_3)_2 + 2Ca(OH)_2 \longrightarrow \underbrace{2CaCO_3 + Mg(OH)_2}_{(Insoluble)} + 2H_2O$$

It is essential to add only the **calculated amount** of  $Ca(OH)_2$  because **excess** will cause artificial hardness.

#### (b) Permanent Hardness

Permanent hardness is introduced when water passes over rocks containing the sulphates or chlorides of both of calcium and magnesium. This type of hardness cannot be removed by boiling or by the addition of slaked lime. Many substances are used for the removal of this type of hardness. The substances used to remove the hardness of water are known as water softeners. The various water softeners are:

(i) Washing soda: It removes both the temporary and permanent hardness by converting soluble calcium and magnesium compounds into insoluble carbonates.

$$CaCl_2 + Na_2CO_3 = CaCO_3 + 2NaCl$$
  
 $CaSO_4 + Na_2CO_3 = CaCO_3 + Na_2SO_4$   
 $Ca(HCO_3)_2 + Na_2CO_3 = CaCO_3 + 2NaHCO_3$   
(Insoluble) (Soluble)

In place of sodium carbonate, caustic soda or sodium phosphate can also be used.

$$MgCl_2 + 2NaOH \longrightarrow Mg(OH)_2 + 2NaCl$$
(Insoluble)

 $3MgSO_4 + 2Na_3PO_4 \longrightarrow Mg_3(PO_4)_2 + 3Na_2SO_4$ 
(Insoluble)

The ionic group is water soluble and the hydrocarbon group is oil soluble. The dirt particles are usually oil containing. As a consequence the hydrocarbon end of the soap is attached to and dissolve in the dirt particles, leaving the ionic end exposed to water. The net effect is to make the dirt particle disperse in the water as a stable emulsion and thus remove it from the object to be cleaned.

<sup>\*</sup>Ordinary soap is the sodium salt of fatty acids. It is used as cleaning agent. The basis for cleaning action of soaps is that they contain a long hydrocarbon chain with an ionic group at one end.

(ii) **Permutit:** Permutit is the technical name given to certain hydrated silicates of aluminium and sodium. It is obtained by fusing sodium carbonate, china clay, silica or quartz. The product is washed with water to remove soluble portion. The remaining crystalline mass sodium aluminosilicate or sodium zeolite (Na<sub>2</sub>Al<sub>2</sub>Si<sub>2</sub>O<sub>8</sub> xH<sub>2</sub>O) is technically called as **permutit.** The sodium ions of permutit are exchanged with calcium and magnesium ions, removing the hardness of the water, when hard water is passed through it (Fig. 5.12).

These ions can be re-exchanged by treating it with brine (NaCl) solution.

$$CaAl_2Si_2O_8 \cdot xH_2O + 2NaCl \longrightarrow Na_2Al_2Si_2O_8 \cdot xH_2O + CaCl_2$$

This method is useful for the removal of both **temporary** and **permanent** hardness of water.

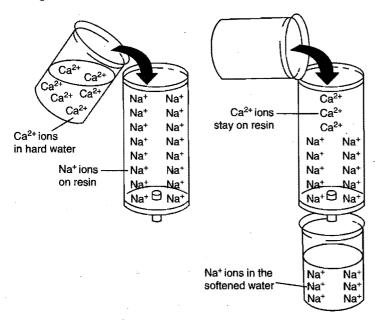

Fig. 5.12 The exchange of one type of ions in a solution by another

(iii) Calgon: The complex salt of metaphosphoric acid, sodium hexametaphosphate  $(NaPO_3)_6$ , is known as calgon. It is represented as  $Na_2[Na_4(PO_3)_6]$ . Calcium and magnesium salts present in hard water react with calgon to give complex salts.  $2CaSO_4 + Na_2[Na_4(PO_3)_6] \longrightarrow Na_2[Ca_2(PO_3)_6] + 2Na_2SO_4$ 

 $2MgSO_4 + Na_2[Na_4(PO_3)_6] \longrightarrow Na_2[Mg_2(PO_3)_6] + 2Na_2SO_4$  $2MgSO_4 + Na_2[Na_4(PO_3)_6] \longrightarrow Na_2[Mg_2(PO_3)_6] + 2Na_2SO_4$ 

This method is especially used softening water for boiler use.

(iv) By ion exchange resins: Ion exchange resins are the most popular water softeners these days. These resins are synthetic substances. The cation exchanger consists of granular insoluble organic acid resin having giant molecules with —SO<sub>3</sub>H or —COOH groups while the anion exchanger contains giant organic molecules with basic groups derived from amines. Ion exchange resins remove all soluble minerals from water. The hard water is first passed through a bed of cation exchanger,

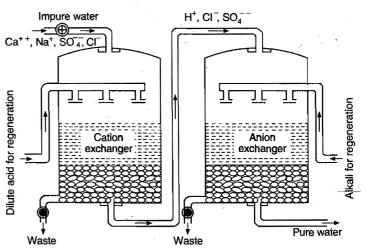

Fig. 5.13 Ion exchanger

which removes the cations like Na<sup>+</sup>, Mg<sup>2+</sup>, Ca<sup>2+</sup> and others by exchanging with H<sup>+</sup> ions.

$$2RH + Ca^{2+} \longrightarrow (R)_2Ca + 2H^+$$
Resin

The water coming from cation exchanger is acidic on account of free  $H^+$ ions. This water is then passed through another bed containing anion exchanger. This exchanger removes anions like  $Cl^-$ ,  $SO_4^{2-}$ ,  $NO_3^-$  by exchanging with  $OH^-$  ions.

$$R$$
—NH<sub>3</sub>OH + Cl $\xrightarrow{}$  R—NH<sub>3</sub>Cl + OH $\xrightarrow{}$  Resin

The OH ions neutralise the H ions.

$$H^+ + OH^- = H_2O$$

This process gives distilled water and can be used in laboratories.

The cation exchanger is regenerated by the action of an acid and the anion exchanger is regenerated by pouring a solution of a suitable sodium salt through it.

#### Disadvantages of Hard Water

(i) In domestic use: Water is required for cooking, bathing and washing of clothes, etc., in our daily life. Hardness upto 100 to 150 ppm in water is tolerable, but if the hardness is more than this, the water is not suitable for domestic use. Pulses and vegetables do not cook well in hard water. Hard water spoils the lustre of utensils. Scales are formed in cooking vessels which cause wastage of fuel and cleaning of the vessels becomes difficult.

Hard water is not fit for bathing as it does not produce sufficient lather with soap. It makes the skin dry. Hard water is unfit for laundry purposes. There is a considerable loss of soap due to formation of insoluble compounds. Yellow stains are formed on the clothes if iron salts are present in hard water.

- (ii) In industrial use: Industries like dyeing, printing textiles, sugar, etc., require large quantities of water. Water containing iron and manganese salts is unfit for use in dyeing and printing textiles because these produce insoluble lakes with dyes.
- (iii) In boiler use: Water is used in producing steam. When hard water is used for production of steam in boilers, it presents three main difficulties:
- (a) Formation of scales: It is the deposition of dissolved minerals in the form of crust within the boiler shell. The crust is hard and heat insulating. It makes wastage of fuel. Sometimes the crust breaks at certain place which leads to an accident.
- **(b) Corrosion:** MgCl<sub>2</sub> present in hard water gets hydrolysed with formation of free HCl. This attacks the metal surface of the boiler and thereby shortens its life.

$$MgCl_2 + H_2O \longrightarrow Mg(OH)Cl + HCl$$

Corrosion is also affected by the presence of dissolved gases like CO<sub>2</sub>, H<sub>2</sub>S, SO<sub>2</sub>, etc., in hard water. Corrosion can be prevented by the addition of suitable amounts of alkalies like NaOH or Na<sub>2</sub>CO<sub>3</sub>.

**(c) Foaming:** It is the formation of bubbles on the surface of the water in the boiler. This occurs due to the presence of suspended particles in water. It causes wastage of fuel.

## Degree of Hardness

The degree of hardness is defined as the number of parts of calcium carbonate or equivalent to various calcium and magnesium salts present in a million parts of water by mass. It is expressed as ppm.

**Example 3.** Find the degree of hardness of a sample of water containing 12 mg of MgSO<sub>4</sub> (Mol. mass 120) per kg of water.

**Solution:** 12 mg of MgSO<sub>4</sub> is present in  $10^3$ g of water. Thus,  $10^6$  g of water contains = 12000 mg of MgSO<sub>4</sub> 120 g MgSO<sub>4</sub> = 100 g of CaCO<sub>3</sub>

So, 12000 mg of MgSO<sub>4</sub> =  $\frac{100}{120} \times \frac{12000}{1000} = 10$  g CaCO<sub>3</sub>

Hardness of water = 10 ppm

**Example 4.** One litre of a sample of hard water contains 1 mg of  $CaCl_2$  and 1 mg of  $MgCl_2$ . Find the total hardness in terms of parts of  $CaCO_3$  per  $10^6$  parts of water by mass.

#### **Solution:**

Mol. mass of  $CaCl_2 = 111$ , Mol. mass of  $MgCl_2 = 95$ 111 grams of  $CaCl_2 = 100$  grams of  $CaCO_3$ 

∴ 1 mg of CaCl<sub>2</sub> 
$$\equiv \frac{100}{111} \times 1$$
 mg of CaCO<sub>3</sub>  
= 0.9 mg of CaCO<sub>3</sub>  
95 grams of MgCl<sub>2</sub>  $\equiv 100$  grams of CaCO<sub>3</sub>  
∴ 1 mg of MgCl<sub>2</sub>  $\equiv \frac{100}{95} \times 1$  mg of CaCO<sub>3</sub>  
= 1.05 mg of CaCO<sub>3</sub>

Thus, one litre of hard water contains (0.9 + 1.05) = 1.95 mg of CaCO<sub>3</sub>

One litre water =  $10^3$  grams =  $10^6$  mg Degree of hardness = 1.95 ppm

# 5.15 HYDROGEN PEROXIDE

Hydrogen peroxide was discovered by the French chemist, L.J. Thenard, in 1818, by the action of sulphuric acid on barium peroxide. It was called oxygenated water.

It occurs in traces in air, rain, snow, some natural waters and juices of certain plants.

## Laboratory Preparation

(i) From sodium peroxide: It is prepared in the laboratory by adding small amounts of sodium peroxide to ice cold water.

$$Na_2O_2 + 2H_2O \longrightarrow 2NaOH + H_2O_2$$

In place of cold water, dilute sulphuric acid (20%) can be used. Sodium peroxide in small amounts at a time is added to cold 20% sulphuric acid.

$$Na_2O_2 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O_2$$

The crystals of hydrated sodium sulphate ( $Na_2SO_4\cdot 10H_2O$ ) are removed by cooling the solution. The solution of hydrogen peroxide obtained always consists some dissolved sodium sulphate. The concentration of  $H_2O_2$  is about 3%.

(ii) From barium peroxide: Hydrogen peroxide can be obtained by adding barium peroxide to dilute sulphuric acid at 0°C. The reaction between anhydrous barium peroxide and sulphuric acid is, however, slow and practically ceases after some time due to the formation of a protective coating of barium sulphate on barium peroxide. This difficulty can be overcome if hydrated barium peroxide is used in place of anhydrous barium peroxide.

$$BaO_2 \cdot 8H_2O + H_2SO_4 = BaSO_4 + H_2O_2 + 8H_2O$$

The barium sulphate formed is filtered off and a solution of H<sub>2</sub>O<sub>2</sub> is obtained.

The use of sulphuric acid has a disadvantage as it catalyses the decomposition of hydrogen peroxide formed. In place of sulphuric acid, weak acids like orthophosphoric acid, carbonic acid are preferred. Barium peroxide on treatment with orthophosphoric acid gives a precipitate of barium phosphate and  $H_2O_2$  which goes into the solution.

$$3BaO_2 + 2H_3PO_4 \longrightarrow Ba_3(PO_4)_2 + 3H_2O_2$$

Insoluble barium phosphate is filtered off. The filtrate consists of hydrogen peroxide.

The barium phosphate is decomposed by dilute sulphuric acid.

$$Ba_3(PO_4)_2 + 3H_2SO_4 \longrightarrow 3BaSO_4 + 2H_3PO_4$$

BaSO<sub>4</sub> is removed by filtration and orthophosphoric acid is used again.

(iii) Merck's process: H<sub>2</sub>O<sub>2</sub> can be obtained by passing a current of CO<sub>2</sub> through a cold pasty solution of barium peroxide in water.

$$BaO_2 + CO_2 + H_2O \longrightarrow BaCO_3 + H_2O_2$$

Barium carbonate being insoluble is filtered off.

#### Manufacture of Hydrogen Peroxide

(i) Auto-oxidation of 2-butyl anthraquinol: This is the most recent process for the manufacture of hydrogen peroxide. 2-Butyl anthraquinone is catalytically reduced to 2-butyl anthraquinol in an organic solvent by passing hydrogen in presence of palladium. It is then oxidised by passing air. The  $H_2O_2$  is extracted with water to give about a 20% solution. 2-Butyl anthraquinone is reformed which is again used. The method, thus, involves alternate oxidation and reduction steps, only hydrogen is consmued in this method (Fig 5.14).

$$\begin{array}{c} OH \\ C_4H_9 \\ H_2(Pd) \\ \hline \\ OH \\ 2\text{-Butyl anthraquinol} \\ \hline \\ O_2\text{(Air)} \\ \hline \\ O \\ C_4H_9 \\ + H_2O_2 \\ \hline \\ O \\ \end{array}$$

Fig. 5.14

(ii) By oxidation of isopropyl alcohol: This industrial method of manufacture of hydrogen peroxide involves the oxidation of isopropyl alcohol with oxygen under slight pressure. The isopropyl alcohol is mixed with a small amount of  $H_2O_2$  and oxygen is passed through at  $70^{\circ}$ C. The  $H_2O_2$  added acts

as an initiator. The alcohol gets oxidised giving acetone and hydrogen peroxide.

$$CH_3CHOHCH_3 + O_2 \longrightarrow CH_3COCH_3 + H_2O_2$$

Acetone and unreacted isopropyl alcohol distil over leaving behind the aqueous solution of hydrogen peroxide.

(iii) Electrolytic process: In this process, the electrolysis of 50% sulphuric acid is carried out at low temperature using platinum electrodes and a current of high density. Peroxy disulphuric acid is formed.

$$2H_2SO_4 \Longrightarrow 2H^+ + 2HSO_4^-$$
  
 $2HSO_4^- \longrightarrow H_2S_2O_8 + 2e^-$  (At anode)  
Peroxy  
disulphuric acid

Peroxy disulphuric acid is distilled. Hydrolysis occurs and a distillate containing about 30%  $H_2O_2$  is obtained.

$$H_2S_2O_8 + 2H_2O \longrightarrow 2H_2SO_4 + H_2O_2$$

In place of 50% H<sub>2</sub>SO<sub>4</sub>, ammonium hydrogen sulphate dissolved in excess of sulphuric acid can be used for electrolysis.

$$NH_4HSO_4 \Longrightarrow NH_4SO_4^- + H^+$$
**At anode**

$$2NH_4SO_4^- \longrightarrow (NH_4)_2S_2O_8 + 2e^-$$

$$Ammonium peroxy disulphate$$

At cathode 
$$2H^+ + 2e^- \longrightarrow H_2(g)$$

The solution containing ammonium peroxy disulphate is heated at 43 mm pressure when its hydrolysis occurs forming hydrogen peroxide.

$$(NH_4)_2S_2O_8 + 2H_2O \longrightarrow 2NH_4 \cdot HSO_4 + H_2O_2$$

Hydrogen peroxide along with water distils over. Ammonium bisulphate can be used again. This method gives 30-40% aqueous solution of hydrogen peroxide.

 $D_2O_2(Deutero\ peroxide)$  can also be prepared by this method.

$$K_2S_2O_8 + 2D_2O \longrightarrow 2KDSO_4 + D_2O_2$$

## Concentration of H<sub>2</sub>O<sub>2</sub> solution

Hydrogen peroxide obtained by the above methods is always in the form of dilute aqueous solution. The concentration of this solution is difficult due to explosive nature of hydrogen peroxide. The explosive decomposition is catalysed by the presence of organic matter and metallic ions. The concentration of the aqueous dilute solution having  $H_2O_2$  is done carefully by the application of following steps:

(i) The dilute solution is concentrated at 60–70°C on a water bath. Water being more volatile than hydrogen peroxide, a considerable amount of water gets evaporated and the concentration of the solution becomes 30%. It is not advisable to concentrate the solution beyond 30% as there is possibility of an explosion by this step.

(ii) The above solution is distilled at 35–40°C under reduced pressure of about 15 mm in the apparatus shown in Fig. 5.15. Repeated distillation gives 90% H<sub>2</sub>O<sub>2</sub>.

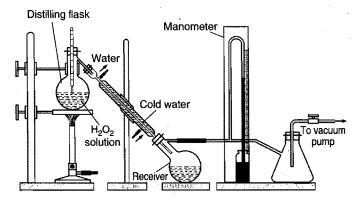

Fig. 5.15 Under low pressure concentration of H<sub>2</sub>O<sub>2</sub>

(iii) Further concentration is achieved by cooling 90% solution with the help of solid CO2 and ether bath till crystallisation sets in. Crystals are separated, melted and refrozen to get 99% pure H<sub>2</sub>O<sub>2</sub>.

#### Storing

The decomposition of  $H_2O_2$  is easily catalysed by metals, rough surfaces, sunlight, dust particles, glass and alkali. It is stored in vessels of pure aluminium or in stone jars in dark. Concentrated solutions of hydrogen peroxide are stored these days in polythene bottles kept in refrigerators. Small amounts of stabilizers such as orthophosphoric acid, acetanilide or sodium stannate are added to the solutions to be stored.

#### Properties of H<sub>2</sub>O<sub>2</sub>

Physical Properties: (i) Pure anhydrous hydrogen peroxide is a syrupy liquid. It is colourless but gives a bluish tinge in thick layers. It is odourless.

- (ii) Its specific gravity is 1.45 at 0°C.
- (iii) It is soluble in water, alcohol and ether.
- (iv) It has bitter taste. It is injurious to skin (blisters are
- (v) It boils at 152°C and freezes at -0.89°C. It begins to decompose at boiling point, however, it can be distilled under reduced pressure.
  - (vi) It is an associated liquid due to hydrogen bonding.
- (vii) The dipole moment of  $H_2O_2$  is little more (2.1 D) than that of  $H_2O$  (1.84 D).

#### **Chemical Properties:**

(i) Stability: It is unstable in nature. It decomposes on standing and heating. It is an example of auto oxidation-reduction reaction.

$$2H_2O_2 = 2H_2O + O_2$$

The oxidation number of oxygen changes to 0 and -2 from -1. Presence of traces of MnO<sub>2</sub>, carbon, alkali or finely divided metals like Pt, Au, Ag accelerate its decomposition. Traces of acid, acetanilide, alcohol or stannates increase its stability.

(ii) Acidic nature: The pure liquid has weak acidic nature but its aqueous solution is neutral towards litmus. It reacts with alkalies and carbonates to give their corresponding peroxides.

$$H_2O_2 + 2NaOH = Na_2O_2 + 2H_2O$$
  
 $H_2O_2 + Ba(OH)_2 = BaO_2 + 2H_2O$   
 $H_2O_2 + Na_2CO_3 = Na_2O_2 + CO_2 + H_2O$ 

(iii) Oxidising nature: It is a powerful oxidising agent. It is an electron acceptor in acidic and alkaline solutions.

$$H_2O_2 + 2H^+ + 2e^- = 2H_2O$$
 (In acidic solutions)  
 $H_2O_2 + 2e^- = 2OH^-$  (In alkaline solutions)

The reactions are generally slow in acid solutions but fast in alkaline solutions.

Oxidising nature of hydrogen peroxide can be interpreted on account of the possession of labile oxygen atom. The potential equation for its oxidising nature can be written as,

$$H_2O_2 \longrightarrow H_2O + O$$

The following examples show the **oxidising nature** of  $H_2O_2$ : (a) It oxidises black lead sulphide (PbS) to white lead sulphate (PbSO<sub>4</sub>).

$$[H_2O_2 \longrightarrow H_2O + O] \times 4$$

$$PbS + 4O \longrightarrow PbSO_4$$

$$PbS + 4H_2O_2 \longrightarrow PbSO_4 + 4H_2O_4$$

(b) It oxidises nitrites to nitrates.

$$\begin{array}{c} H_2O_2 \longrightarrow H_2O + O \\ NaNO_2 + O \longrightarrow NaNO_3 \end{array}$$

$$\begin{array}{c} NaNO_2 + H_2O_2 \longrightarrow NaNO_3 + H_2O \end{array}$$

(c) It oxidises sulphites into sulphates.

$$H_2O_2 \longrightarrow H_2O + O$$

$$Na_2SO_3 + O \longrightarrow Na_2SO_4$$

$$Na_2SO_3 + H_2O_2 \longrightarrow Na_2SO_4 + H_2O$$

$$H_2O_2 \longrightarrow H_2O + O$$

$$Na_3AsO_3 + O \longrightarrow Na_3AsO_4$$

$$Na_3AsO_3 + H_2O_2 \longrightarrow Na_3AsO_4 + H_2O$$

(e) It liberates iodine from potassium iodide.

$$\begin{aligned} & H_2O_2 \longrightarrow H_2O + O \\ & 2KI + H_2SO_4 + O \longrightarrow K_2SO_4 + I_2 + H_2O \\ \hline & 2KI + H_2SO_4 + H_2O_2 \longrightarrow K_2SO_4 + I_2 + 2H_2O \end{aligned}$$
 or 
$$2I^- + H_2O_2 + 2H^+ \longrightarrow I_2 + 2H_2O$$

(f) It oxidises  $H_2S$  into sulphur.

$$\begin{array}{c} H_2O_2 \longrightarrow H_2O + O \\ H_2S + O \longrightarrow H_2O + S \end{array}$$

$$\begin{array}{c} H_2S + H_2O_2 \longrightarrow 2H_2O + S \end{array}$$

(g) It oxidises acidified ferrous sulphate to ferric sulphate.

$$H_2O_2 \longrightarrow H_2O + O$$

$$2FeSO_4 + H_2SO_4 + O \longrightarrow Fe_2(SO_4)_3 + H_2O$$

$$2FeSO_4 + H_2SO_4 + H_2O_2 \longrightarrow Fe_2(SO_4)_3 + 2H_2O$$
or 
$$2Fe^{2+} + H_2O_2 + 2H^+ \longrightarrow 2Fe^{3+} + 2H_2O$$

**(h)** It oxidises acidified potassium ferrocyanide to potassium ferricyanide.

$$\begin{aligned} &H_2O_2 \longrightarrow H_2O + O \\ \frac{2K_4Fe(CN)_6 + H_2SO_4 + O \longrightarrow 2K_3Fe(CN)_6 + K_2SO_4 + H_2O}{2K_4Fe(CN)_6 + H_2SO_4 + H_2O_2 \rightarrow 2K_3Fe(CN)_6 + K_2SO_4 + 2H_2O} \\ \text{or } &2[Fe(CN)_6]^{4-} + H_2O_2 + 2H^+ \longrightarrow 2[Fe(CN)_6]^{3-} + 2H_2O \end{aligned}$$

(i) It oxidises formaldehyde to formic acid. This oxidation occurs in presence of pyrogallol and in alkaline medium.

$$\begin{aligned} & \text{H}_2\text{O}_2 \longrightarrow \text{H}_2\text{O} + \text{O} \\ & \underline{ \text{HCHO} + \text{O} \longrightarrow \text{HCOOH} } \\ & \underline{ \text{HCHO} + \text{H}_2\text{O}_2 \longrightarrow \text{HCOOH} + \text{H}_2\text{O} } \end{aligned}$$
 or 
$$\begin{aligned} & \text{2HCHO} + \text{H}_2\text{O}_2 \longrightarrow \text{2HCOOH} + \text{H}_2 \end{aligned}$$

(j) Benzene in presence of ferrous sulphate is oxidised to phenol.

$$2 \bigcirc + H_2O_2 \xrightarrow{\text{FeSO}_4} 2 \bigcirc$$

(k) It dissolves the chromic hydroxide precipitate present in NaOH solution forming a yellow solution of sodium chromate.

$$[H_2O_2 \longrightarrow H_2O + O] \times 3$$

$$2Cr(OH)_3 + 4NaOH + 3O \longrightarrow 2Na_2CrO_4 + 5H_2O$$

$$2Cr(OH)_3 + 4NaOH + 3H_2O_2 \longrightarrow 2Na_2CrO_4 + 8H_2O$$

(1) A solution of chromic acid in sulphuric acid or acidified potassium dichromate is oxidised to blue peroxide of chromium (CrO<sub>5</sub>) which is unstable, however, it is soluble in ether and produces blue coloured solution.

$$K_2Cr_2O_7 + H_2SO_4 \longrightarrow K_2SO_4 + H_2Cr_2O_7$$

$$[H_2O_2 \longrightarrow H_2O + O] \times 4$$

$$H_2Cr_2O_7 + 4O \longrightarrow 2CrO_5 + H_2O$$

$$K_2Cr_2O_7 + H_2CO_7 + H_2O_7 \longrightarrow 2CrO_7 + K_2O_7 + 5O_7$$

 $K_2Cr_2O_7 + H_2SO_4 + 4H_2O_2 \longrightarrow 2CrO_5 + K_2SO_4 + 5H_2O_4$ 

Peroxide of chromium decomposes to form chromic sulphate and oxygen.

$$4CrO_5 + 6H_2SO_4 \longrightarrow 2Cr_2(SO_4)_3 + 6H_2O + 7O_2$$

Peroxide of chromium is represented as

(Butterfly shape)

(m) In alkaline medium, it oxidises manganese sulphate (a manganous salt) to manganese dioxide.

$$MnSO_4 + H_2O_2 + 2NaOH \longrightarrow MnO_2 + Na_2SO_4 + 2H_2O$$
  
or  $Mn^{2+} + H_2O_2 \longrightarrow Mn^{4+} + 2OH^-$ 

(n) In acidic solution, mercury is oxidised to mercuric oxide.

$$Hg + H_2O_2 \xrightarrow{H_2SO_4} HgO + H_2O$$

(o) Bleaching action: Due to its oxidising nature, it acts as a bleaching agent.

Coloured material + O ---- Colourless

It bleaches materials like silk, hair, ivory, cotton, wool, etc.

When used as a hair bleach (a 6% solution), it acts by oxidizing the pigments in the hair.

(iv) Reducing nature: It can also act as a reducing agent towards powerful oxidising agents.

$$H_2O_2 \longrightarrow 2H^+ + O_2 + 2e^-$$

In alkaline solution, however, its reducing action is more effective.

$$H_2O_2 + 2OH \longrightarrow 2H_2O + O_2 + 2e^-$$

The potential equation when H<sub>2</sub>O<sub>2</sub> acts as a reducing agent can be expressed as,

$$H_2O_2 + O \longrightarrow H_2O + O_2$$

(a) Ag<sub>2</sub>O is reduced to silver.

$$Ag_2O + H_2O_2 \longrightarrow 2Ag + H_2O + O_2$$

(b) It reduces ozone to oxygen.

$$H_2O_2 + O_3 \longrightarrow H_2O + 2O_2$$

(c) Manganese dioxide in acidic medium is reduced to manganous salt.

$$MnO_2 + H_2SO_4 + H_2O_2 \longrightarrow MnSO_4 + 2H_2O + O_2$$

(d) Lead dioxide is reduced to lead monoxide.

$$PbO_2 + H_2O_2 \longrightarrow PbO + H_2O + O_2$$

(e) Red lead in presence of HNO<sub>3</sub> is reduced to plumbous salt.

$$Pb_3O_4 + 6HNO_3 + H_2O_2 \longrightarrow 3Pb(NO_3)_2 + 4H_2O + O_2$$

(f) Chlorine and bromine are reduced to corresponding hydracids.

$$Cl_2 + H_2O_2 \longrightarrow 2HCl + O_2$$

This reaction can be shown in following steps:

$$\begin{array}{c} Cl_2 + H_2O \longrightarrow HCl + HClO \\ \underline{HClO + H_2O_2 \longrightarrow HCl + H_2O + O_2} \\ \hline Cl_2 + H_2O_2 \longrightarrow 2HCl + O_2 \\ \\ Similarly \;,\;\; Br_2 + H_2O_2 \longrightarrow 2HBr + O_2 \end{array}$$

(g) It reduces acidified KMnO<sub>4</sub> solution, *i.e.*, acidified KMnO<sub>4</sub> is decolourised by H<sub>2</sub>O<sub>2</sub>.

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5O$$
  
 $5H_2O_2 + 5O \longrightarrow 5H_2O + 5O_2$ 

$$2KMnO_{4} + 3H_{2}SO_{4} + 5H_{2}O_{2} \rightarrow K_{2}SO_{4} + 2MnSO_{4} + 8H_{2}O + 5O_{2}$$

or 
$$2MnO_4^- + 6H^+ + 5H_2O_2 \longrightarrow 2Mn^{2+} + 8H_2O + 5O_2$$

(h) Potassium ferricyanide (alk. solution) is reduced to potassium ferrocyanide.

$$2K_3Fe(CN)_6 + 2KOH \longrightarrow 2K_4Fe(CN)_6 + H_2O + O$$
  
 $H_2O_2 + O \longrightarrow H_2O + O_2$ 

$$2K_3Fe(CN)_6 + 2KOH + H_2O_2 \longrightarrow 2K_4Fe(CN)_6 + 2H_2O + O_2$$
  
or  $2[Fe(CN)_6]^{3-} + 2OH^- + H_2O_2 \longrightarrow 2[Fe(CN)_6]^{4-} + 2H_2O + O_2$ 

(i) Hypohalites are reduced to halides.

$$NaOCl + H_2O_2 \longrightarrow NaCl + H_2O + O_2$$

(j) KIO<sub>4</sub> is reduced to KIO<sub>3</sub>,

$$KIO_4 + H_2O_2 \longrightarrow KIO_3 + H_2O + O_2$$

(v) Addition reactions: Hydrogen peroxide is capable of adding itself to ethylenic linkage.

$$\begin{array}{cccc} CH_2 & HO & CH_2OH \\ \parallel & + & \parallel & \longrightarrow & \parallel \\ CH_2 & HO & CH_2OH \\ Ethylene & Ethylene glycol \end{array}$$

#### **Uses**

Hydrogen peroxide in the form of aqueous solution is used:

- (i) in the bleaching of delicate materials such as wool, silk, cotton, bone, ivory, hair, etc.
- (ii) as a valuable antiseptic and germicide for washing wounds, teeth and ears under the name of **perhydrol**.
- (iii) In general a 3% H<sub>2</sub>O<sub>2</sub> aqueous solution is used as a mild antiseptic. Contact of H<sub>2</sub>O<sub>2</sub> with blood catalyzes its disproportionation into oxygen and water, which cleanses the wound.
- (iv) As it oxidizes unpleasant effluents without producing any harmful by-products,  $H_2O_2$  is widely used as an oxidizing agent in the control of pollution.
  - (vi) for restoring colour of old paintings.
  - (v) as an oxidising agent in the laboratory.
- (vi) as 'antichlor' to remove traces of chlorine and hypochlorite.
- (vii) highly concentrated solution (about 40%) of  $H_2O_2$  is used to oxidise petrol, alcohol and hydrazine hydrate for the propelling of rockets and torpedoes.

$$NH_2 \cdot NH_2 + 2H_2O_2 \longrightarrow N_2 + 4H_2O$$

The reaction is highly exothermic and is accompanied by a large increase in volume.

(vii) in the detection of Ti<sup>4+</sup>, V<sup>5+</sup> and Cr<sup>3+</sup> ions.

(viii) It is used to produce sodium peroxoborate.  $Na_2B_2(O_2)_2(OH)_4$  in hexahydrate state, it is used as a brightner in washing powders.

$$2NaBO_2 + 2H_2O_2 + 6H_2O \longrightarrow$$

$$Na_2[(OH)_2B(O-O)_2B(OH)_2]6H_2O$$

Structure of peroxoborate ion may be given as,

#### M Tests of Hydrogen Peroxide

(i) A filter paper with a stain of black lead sulphide (PbS) when brought in contact with a solution of H<sub>2</sub>O<sub>2</sub>, the black stain turns white.

$$[PbS \longrightarrow PbSO_4]$$

(ii) An acidified solution of titanium salt when treated with H<sub>2</sub>O<sub>2</sub>, yellow or orange colour is developed due to formation of pertitanic acid,

$$[Ti(SO4)2 + H2O2 + 2H2O = H2TiO4 + 2H2SO4].$$
Pertitanic acid

- (iii) H<sub>2</sub>O<sub>2</sub> when shaken with acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> with little ether, blue colour is produced. This is due to the formation of peroxide of chromium (perchromic acid).
- (iv) It liberates iodine from KI solution which gives blue colour with starch solution.
- (v) It decolourises acidified potassium permanganate solution.

## Strength of H<sub>2</sub>O<sub>2</sub> solution

Strength of the sample of hydrogen peroxide is generally expressed in terms of the volume of oxygen at NTP that one volume of hydrogen peroxide gives on heating. The commercial samples are marked as '10 volume', '15 volume' or '20 volume'. '10 volume' means that one volume of hydrogen peroxide on heating gives 10 volume of oxygen at NTP. 10 mL of a '20 volume' solution of  $H_2O_2$  will liberate  $10 \times 20 = 200$  mL of oxygen at NTP.

Sometimes the concentration of  $H_2O_2$  in a solution is expressed as percentage of  $H_2O_2$  in solution, *i.e.*, g/100 mL. Thus, 30% hydrogen peroxide means that 30 g of  $H_2O_2$  is present in 100 mL of solution. '10 volume' solution of  $H_2O_2$  is 3.035% solution, *i.e.*, 3.035 g of  $H_2O_2$  present in 100 mL of the solution. This calculation can be made in the following manner.

$$2H_2O_2 \longrightarrow 2H_2O + O_2$$
  
 $2(2 + 32)$  22400 mL  
= 68 g at NTP

22400 mL of oxygen is obtained at NTP from

 $= 68 \text{ g of } H_2O_2$ 

10 mL of oxygen is obtained at NTP from = 
$$\frac{68}{22400} \times 10$$
  
= 0.03035 g H<sub>2</sub>O<sub>2</sub>

1 mL of  $H_2O_2$  solution contains = 0.03035 g  $H_2O_2$ 100 mL of  $H_2O_2$  solution contains = 0.03035 × 100

$$= 3.035 g H_2O_2$$

or the solution is 3.035%

or concentration or strength of 10 volume of  $H_2O_2$  solution =  $3.035 \times 10 = 30.35$  g/litre

**Normality** of this solution can be calculated if we know the equivalent mass of hydrogen peroxide.

Equivalent mass of hydrogen peroxide  $=\frac{68}{32} \times 8 = 17.0$ 

$$\begin{bmatrix} 2H_2O_2 \longrightarrow 2H_2O + O_2 \\ 68 \text{ g} & 32 \text{ g} \end{bmatrix}$$

Number of gram equivalents in 10 volume hydrogen peroxide solution

$$= \frac{\text{concentration or strength per litre}}{\text{equivalent mass}} = \frac{30.35}{17} = 1.785$$

Normality of 10 volume solution = 1.785 N

Similarly, the concentration of '20 volume' hydrogen peroxide solution means 6.070% or 60.70 g/litre or 3.57 N.

Let volume strength is V'.

V litre O<sub>2</sub> will be given by 1 litre then at NTP

g/litre strength of 
$$H_2O_2 = \frac{68}{22.4} \times V$$

$$N = \frac{\text{Strength}}{\text{EM}} = \frac{68}{22.4} \text{ V/17} = \frac{V}{5.6}$$

i.e., Volume strength =  $5.6 \times \text{Normality}$ Similarly, Volume strength =  $11.2 \times \text{Molarity}$ 

# Structure of Hydrogen Peroxide

The vapour density as determined by Victor Meyer method at  $90^{\circ}\text{C}$  is 17. Hence, the molecular mass of  $\text{H}_2\text{O}_2$  is 34. This value has been confirmed by depression of freezing point method also. Thenard found that 17 parts by mass of hydrogen peroxide gives 9 parts by mass of water and 8 parts by mass of oxygen. Thus the empirical formula is OH and the molecular formula is  $\text{H}_2\text{O}_2$ .

Two formulae have been suggested for hydrogen peroxide.

Evidence in favour of Kingzett's formula: This formula explains the oxidising properties of  $H_2O_2$  as the oxygen linked by coordinate bond is easily lost.

$$H \longrightarrow 0 \longrightarrow H \longrightarrow 0 + 0$$

Evidence in favour of Baeyer's formula: (i) Hydrogen peroxide behaves as weak dibasic acid as one or both the hydrogen atoms can be replaced by univalent basic atoms forming salts like Na—O—O—H and Na—O—O—Na (Na<sub>2</sub>O<sub>2</sub>). This suggests that the one molecule of hydrogen peroxide consists of two hydroxyl groups.

(ii) The formation of ethylene glycol from ethylene supports Baeyer's formula.

$$\begin{array}{cccc} CH_2 - & HO & CH_2OH \\ \parallel & + & \parallel & \longrightarrow & \parallel \\ CH_2 & HO & CH_2OH \end{array}$$

It is proposed, therefore, that hydrogen peroxide is a tautomeric mixture of two forms in equilibrium.

$$H - O - O - H \longleftrightarrow H \longrightarrow O \rightarrow O$$

The calculated value of the single bond O—O distance is 1.48 Å and X-ray measurements do show that in hydrogen peroxide, O—O bond distance is  $1.46 \pm 0.03$  Å. The value of dipole moment of  $H_2O_2$  is 2.1 D. This suggests that all the four atoms do not lie in the same plane. The molecule can be pictured as lying on the spine of a book open to an angle of  $94^\circ$ . The hydrogen atoms are present one on each cover and H—O bonds making angles of  $97^\circ$  with the O—O bond as shown in Fig. 5.16. The bond distance between O—H is 0.97 Å.

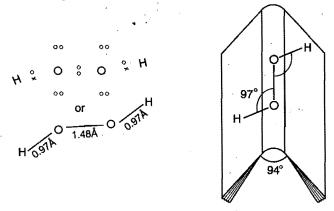

Fig. 5.16 Structure of H<sub>2</sub>O<sub>2</sub>

Structure of H<sub>2</sub>O<sub>2</sub> is slightly different in gas phase and crystalline phase.

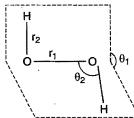

Fig. 5.17 Gas phase structure of  $H_2O_2$  (  $r_1$  = 147.5 pm,  $r_2$  = 95 pm,  $\theta_1$  = 111.5°,  $\theta_2$  = 94.8° )

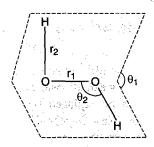

Fig. 5.18 Crystalline phase structure of  $H_2O_2$  ( $r_1=98.5$  pm,  $r_2=145.8$  pm,  $\theta_1=90.2^\circ$ ,  $\theta_2=101.9^\circ$ )

#### Example 5. Explain the following:

- (i) Why hydrated barium peroxide is used in the preparation of hydrogen peroxide instead of the anhydrous variety?
- (ii) Phosphoric acid is preferred to sulphuric acid in the preparation of  $H_2O_2$  from barium peroxide.
- (iii) Statues coated with white lead on long exposure to atmosphere turn black and the original colour can be restored on treatment with  $H_2O_2$ . [Roorkee 1987]
- **Solution:** (i) If anhydrous barium peroxide is used in the preparation, the barium sulphate, thus formed, forms an insoluble protective coating on the surface of solid barium peroxide. This prevents the further reaction of the acid, *i.e.*, causing the reaction to stop. If, however, hydrated barium peroxide (in the form of thin paste) is used, the water causes to dislodge the insoluble BaSO<sub>4</sub> from the surface of BaO<sub>2</sub>. BaSO<sub>4</sub> thus settles at the bottom of the reaction vessel and the reaction continues without any difficulty.
- (ii) When phosphoric acid is used in the preparation of  $H_2O_2$  from  $BaO_2$ , it plays the double role. It liberates  $H_2O_2$  and also acts as a preservator by retarding its decomposition.
- (iii) White lead is used as a pigment. The statues coated with white lead get blackened due to the action of  $H_2S$  present in atmosphere in traces.

$$Pb(OH)_2 \cdot 2PbCO_3 + 3H_2S \longrightarrow 3PbS + 2CO_2 + 4H_2O$$
White lead Black

When blackened statues are treated with H<sub>2</sub>O<sub>2</sub>, the PbS is oxidised to PbSO<sub>4</sub> which is colourless (white).

$$PbS + 4H_2O_2 \longrightarrow PbSO_4 + 4H_2O$$
White

#### **Example 6.** Explain the following:

- (i) Soft water lathers with soap but not hard water.
- (ii) Temporary hard water becomes soft on boiling.
- (iii) Water can extinguish most fires but not petrol fire.
- (iv) Hard water is softened before use in boilers.

**Solution:** (i) Hard water contains calcium and magnesium salts. These react with soap to form insoluble calcium and magnesium salts of fatty acids, *i.e.*, form scum and not lather.

$$2RCOONa + Ca^{2+} \longrightarrow (RCOO)_2Ca + 2Na^+$$
Soap Insoluble

$$2RCOONa + Mg^{2+} \longrightarrow (RCOO)_2Mg + 2Na^+$$

(ii) Temporary hardness of water is due to the presence of soluble bicarbonates of calcium and magnesium. On boiling, the bicarbonates are converted into insoluble carbonates which can be removed by filtration.

$$\begin{array}{c} \text{Ca}(\text{HCO}_3)_2 \longrightarrow \text{CaCO}_3 \, + \, \text{H}_2\text{O} \, + \, \text{CO}_2 \\ \\ \text{Mg}(\text{HCO}_3)_2 \longrightarrow \text{MgCO}_3 \, + \, \text{H}_2\text{O} \, + \, \text{CO}_2 \\ \\ \text{Soluble} \\ \\ \text{Insoluble} \end{array}$$

- (iii) When water poured over petrol fire, petrol being lighter than water floats over water and fire spreads instead being extinguished.
- (iv) Hard water consists bicarbonates and other soluble salts of calcium and magnesium. When hard water is evaporated in boilers, scales of precipitated carbonates of calcium and magnesium along with other salts such as sulphates, chlorides, etc., are formed. In order to avoid the formation of scales hard water is first softened before use in boilers.

#### **Example 7.** Explain the following:

- (i) A small amount of acid or alkali is added before electrolysis of water.
- (ii) The electrolysis of water for manufacturing hydrogen gas is always carried out in the presence of acid  $(H_2SO_4)$  or alkali (KOH), yet no  $SO_4^{2-}$  or  $K^{+}$  ions are discharged.
- (iii) A solution of ferric chloride acidified with HCl is unaffected when hydrogen is bubbled through it, but gets reduced when zinc is added to some acidified solution.
- (iv) When sodium hydride in fused state is electrolysed, hydrogen is discharged at anode.
- **Solution:** (i) Pure water being a weak electrolyte and feebly ionised is bad conductor of electricity. In order to make it a good conductor, a small amount of acid or alkali is added before electrolysis.
- (ii) Sulphate and potassium ions are not discharged as the discharge potential of  $SO_4^{2-}$  is much higher than  $OH^-$  ions and the discharge potential of  $K^+$  ions is much higher than  $H^+$  ions.
- (iii) Molecular (ordinary) hydrogen is not so reactive as hydrogen at the moment of formation. Zinc reacts with the acid to produce nascent hydrogen which reduces ferric chloride into ferrous chloride.
- (iv) Sodium hydride is an electrovalent compound in which hydrogen is present as an anion, H. On electrolysis, it is discharged at anode.

$$NaH \rightleftharpoons Na^{+} + H^{-}$$
Cathode
$$Na^{+} + e^{-} \longrightarrow Na$$

$$H^{-} \longrightarrow H + e^{-}$$

$$2H \longrightarrow H_{2} \uparrow$$

#### **Example 8.** What happens when?

(a) An alkaline solution of potassium ferricyanide is reacted with  $H_2O_2$ .

- (b) Hydrogen peroxide is added to acidified potassium permanganate.
- (c) Hydrogen peroxide is added to ferrous ammonium sulphate solution. [Roorkee 1985]
- (d) Chromium hydroxide is treated with hydrogen peroxide in the presence of sodium hydroxide. [M.L.N.R. 1992]
- (e) Concentrated caustic potash solution is spilled on granulated zinc.
  - (f) Hydrolith is treated with water.
  - (g) Heavy water reacts with aluminium carbide.

#### Solution:

(a) Potassium ferricyanide is reduced to potassium ferrocyanide.

$$2K_3Fe(CN)_6 + 2KOH \longrightarrow 2K_4Fe(CN)_6 + H_2O + O$$
  
 $H_2O_2 + O \longrightarrow H_2O + O_2$ 

$$2K_3Fe(CN)_6 + 2KOH + H_2O_2 \longrightarrow 2K_4Fe(CN)_6 + 2H_2O + O_2$$

(b) Potassium permanganate is decolourised due to reduction.

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5O$$
$$[H_2O_2 + O \longrightarrow H_2O + O_2] \times 5$$

$$2KMnO_4 + 3H_2SO_4 + 5H_2O_2 \longrightarrow$$

$$K_2SO_4 + 2MnSO_4 + 8H_2O + 5O_2$$

(c) Ferrous ammonium sulphate is oxidised to ferric salt.

(d) Chromium hydroxide is converted into soluble yellow sodium chromate.

$$[H_2O_2 \longrightarrow H_2O + O] \times 3$$
 
$$2Cr(OH)_3 + 4NaOH + 3O \longrightarrow 2Na_2CrO_4 + 5H_2O$$

$$2Cr(OH)_3 + 4NaOH + 3H_2O_2 \longrightarrow 2Na_2CrO_4 + 8H_2O$$

(e) Zinc dissolves in caustic potash solution evolving hydrogen.

$$Zn + 2KOH \longrightarrow K_2ZnO_2 + H_2\uparrow$$

(f) Hydrolysis of CaH2 occurs with evolution of H2.

$$CaH_2 + 2H_2O \longrightarrow Ca(OH)_2 + 2H_2\uparrow$$

(g) Deuteromethane is evolved.

$$Al_4C_3 + 12D_2O \longrightarrow 4Al(OD)_3 + 3CD_4$$
Heavy water Deuteromethan

**Example 9.** A 5.0 cm<sup>3</sup> solution of  $H_2O_2$  liberates 0.508 g of iodine from acidified KI solution. Calculate the strength of  $H_2O_2$  solution in terms of volume strength at STP. [I.I.T. 1995]

**Solution:** 

$$H_2O_2 + H_2SO_4 + 2KI \longrightarrow K_2SO_4 + I_2 + 2H_2O_34 g$$
  
= 254 g

254 g of I<sub>2</sub> is obtained from 34 g H<sub>2</sub>O<sub>2</sub>

0.508 g of I<sub>2</sub> is obtained from H<sub>2</sub>O<sub>2</sub> = 
$$\frac{34}{254} \times 0.508$$
  
= 0.068 g

5 mL of the solution contains =  $0.068 \text{ g H}_2\text{O}_2$ 

1 mL of the solution contains 
$$=\frac{0.068}{5}$$
 g H<sub>2</sub>O<sub>2</sub>  
= 0.0136 g H<sub>2</sub>O<sub>2</sub>

$$2H_2O_2 \longrightarrow 2H_2O + O_2$$
 $68 \text{ g}$   $22400 \text{ mL}$ 

68 g of  $H_2O_2$  gives oxygen at STP = 22400 mL 0.0136 g of  $H_2O_2$  will give oxygen at STP

$$= \frac{22400}{68} \times 0.0136$$
$$= 4.48 \text{ mL}$$

i.e., 1 mL of H<sub>2</sub>O<sub>2</sub> solution gives 4.48 mL of oxygen.

So, strength of  $H_2O_2$  solution = 4.48 volume.

Example 10. Calculate the hardness of water sample which contains 0.001 mole of MgSO<sub>4</sub> dissolved per litre of water.

$$0.001 \text{ mole } MgSO_4 = 0.001 \times 120 \text{ g } MgSO_4$$
  
=  $0.120 \text{ g } MgSO_4$ 

We know that, 
$$120 \text{ g MgSO}_4 \equiv 100 \text{ g CaCO}_3$$

So, 
$$0.120 \text{ g MgSO}_4 \equiv 0.1 \text{ g CaCO}_3$$

 $10^3$  g of water (one litre) contains = 0.1 g CaCO<sub>3</sub>

$$10^6$$
 g of water contains =  $\frac{0.1}{10^3} \times 10^6$  = 100 g CaCO<sub>3</sub>

So, the hardness of water = 100 ppm

**Example 11.** Aqueous solution of an inorganic compound (x) shows the following reactions:

- (i) It decolourises an acidified  $KMnO_4$  solution accompanied by the evolution of oxygen.
  - (ii) It liberates iodine from an acidified KI solution.
- (iii) It gives a brown precipitate with alkaline  $KMnO_4$  solution with evolution of oxygen.
  - (iv) It removes black stains from old oil paintings.

Identify, (x) and give chemical equations for the reactions at steps (i) to (iv). [Roorkee 1993]

**Solution:** In reactions (i) and (iii) (x) acts as a reducing agent while in reaction (ii) it acts as an oxidising agent. Thus, these reactions indicate that (x) is  $H_2O_2$  which is further confirmed from reaction (iv).

$$\underbrace{K_2SO_4 + 2MnSO_4}_{Soluble, colourless} + 8H_2O + 5O_2$$

(ii) 
$$2KI + H_2SO_4 + H_2O_2 \rightarrow K_2SO_4 + I_2 + 2H_2O$$

(iii) 
$$2\text{KMnO}_4 + 3\text{H}_2\text{O}_2 \rightarrow 2\text{KOH} + 2\text{MnO}_2 + 2\text{H}_2\text{O} + 3\text{O}_2$$

Brown

(iv) PbS + 
$$4H_2O_2 \rightarrow PbSO_4 + 4H_2O$$
Black White

**Example 12.** Hydrogen peroxide acts both as an oxidising and as a reducing agent in alkaline solution towards certain first row transition metal ions. Illustrate both these properties of  $H_2O_2$  using chemical equations. [I.I.T. 1998]

**Solution:** Chromium hydroxide is oxidised by  $H_2O_2$  in presence of NaOH into sodium chromate

$$[H_2O_2 \longrightarrow H_2O + O] \times 3$$

$$2Cr(OH)_3 + 4NaOH + 3O \longrightarrow 2Na_2CrO_4 + 5H_2O$$

$$2Cr(OH)_3 + 4NaOH + 3H_2O_2 \longrightarrow 2Na_2CrO_4 + 8H_2O$$

Potassium ferricyanide is reduced to ferrocyanide in presence of KOH by  $H_2O_2$ .

$$2K_3Fe(CN)_6 + 2KOH \longrightarrow 2K_4Fe(CN)_6 + H_2O + O$$
  
 $H_2O_2 + O \longrightarrow H_2O + O_2$ 

$$2K_3Fe(CN)_6 + 2KOH + H_2O_2 \longrightarrow 2K_4Fe(CN)_6 + 2H_2O + O_2$$

- **Example 13.** (a) A mixture of hydrazine and  $H_2O_2$  with Cu(II) catalyst is used a rocket propellant. Why?
- (b) Can concentrated  $H_2SO_4$  be used for drying  $H_2$  gas? Justify.
- (c) The process  $\frac{1}{2}H_2(g) + e \longrightarrow H^-(g)$  is endothermic  $(\Delta H = +151 \text{ kJ mol}^{-1})$ , yet salt like hydrides are known. How do you account for this?

**Solution:** (a) The reaction between hydrazine and  $H_2O_2$  is highly exothermic and is accompanied by a large increase in the volume of the products. Hence, the mixture is used as rocket propellant.

$$N_2H_4(l) + 2H_2O_2(l) \xrightarrow{Cu(II)} N_2(g) + 4H_2O(g)$$

- (b) Concentrated  $H_2SO_4$  cannot be used for drying  $H_2$  gas as the absorption of moisture by  $H_2SO_4$  is highly exothermic in nature. The heat so produced causes hydrogen to catch fire as hydrogen is highly inflammable.
- (c) Alkali and alkaline earth metals combine with hydrogen and form ionic hydrides in spite of the fact that formation of  $H^-$  ions is an endothermic process. This is due to the reason that high lattice enthalpy released during formation of solid hydride from  $M^+$  or  $M^{2+}$  and  $H^-$  ions is more than needed for the formation of  $H^-$  ions from  $H_2$ .

**Example 14.** (a) Compare the structures of  $H_2O$  and  $H_2O_2$ . (b) Do you expect different products in solution when  $AlCl_3$  is treated separately with (i) normal water, (ii) acidified water and (iii) alkaline water?

**Solution:** (a)  $H_2O$  has a bent structure with HOH bond angle is  $104.5^{\circ}$ .  $H_2O_2$  has an open book structure with H—O—O angle equal to  $94.8^{\circ}$  and dihedral angle equal to  $111.5^{\circ}$  in gaseous phase.

(b) AlCl<sub>3</sub> is a salt of a weak base and a strong acid. In normal water, it undergoes hydrolysis.

$$AlCl_3(s) + 3H_2O(l) \longrightarrow Al(OH)_3(s) + 3HCl(aq)$$
Base Acid

In acidic water,  $H^+$  ions react with Al(OH)<sub>3</sub> giving Al<sup>3+</sup>(aq) ions.

$$AlCl_3(s) \xrightarrow{\text{Acidified}} Al^{3+}(aq) + 3Cl^{-}(aq)$$

In alkaline water,  $Al(OH)_3$  reacts to form soluble tetrahydroxo-aluminate complex or meta-aluminate ions  $[AlO_2^-(aq)]$ .

$$Al(OH)_3 + OH^-(aq) \longrightarrow [Al(OH)_4]^-(aq) \text{ or } AlO_2^-(aq) + 2H_2O$$

$$AlCl_3(s) \xrightarrow{Alkaline} AlO_2^-(aq) + 2H_2O(l) + 3Cl^-(aq)$$

**Example 15.** Would you expect the hydrides of N, O and F to have lower boiling points than the hydrides of their subsequent group members? Give reasons.

**Solution:** On the basis of molecular masses of NH<sub>3</sub>, H<sub>2</sub>O and HF, their boiling points are expected to be lower than subsequent group member hydrides. However, on account of high electronegativity of N, O and F, the magnitude of hydrogen bonding is appreciable in their hydrides, *i.e.*, aggregation of molecules occurs. Hence, the boiling points of NH<sub>3</sub>, H<sub>2</sub>O and HF will be higher than the hydrides of their subsequent group members.

**Example 16.** What do you understand by (i) electron deficient (ii) electron precise and (iii) electron rich compounds of hydrogen? Provide justification with suitable examples.

**Solution:** (i) The hydrides which do not possess sufficient number of valence electrons to form normal covalent bonds, are termed electron deficient hydrides. Examples are the hydrides of group 13 such as BH<sub>3</sub>, AlH<sub>3</sub>, etc. They generally exist in polymeric forms.

- (ii) The hydrides which possess exact number of electrons to form covalent bonds are termed electron precise hydrides. Examples are the hydrides of group 14 such as CH<sub>4</sub>, SiH<sub>4</sub>, GeH<sub>4</sub>, etc.
- (iii) The hydrides which have lone pair or pairs of electrons, *i.e.*, have more electrons than required to form normal covalent bonds are termed electron rich hydrides. Examples are the hydrides of group 15, 16 and 17 such as NH<sub>3</sub>, H<sub>2</sub>O, HF, etc.

**Example 17.** What do you understand by the term non-stoichiometric hydrides? Do you expect these types of hydrides to be formed by alkali metals? Justify your answer.

**Solution:** The hydrides in which the ratio of the metal and hydrogen is found to be fractional are called non-stoichiometric hydrides. It is also observed that this fractional ratio is not fixed

but varies with the temperature and pressure. Such hydrides are formed by d- and f-block elements. In these hydrides, hydrogen atoms occupy holes in the metal lattice. Usually all the holes are not occupied, *i.e.*, some holes always remain vacant and thus, these compounds are non-stoichiometric.

Alkali metals do not form non-stoichiometric hydrides as each sodium atom loses its valency electron which is accepted by hydrogen atom to form H<sup>-</sup> ion. In this way, an ionic compound, Na<sup>+</sup> H<sup>-</sup>, is formed.

# O

# **SUMMARY AND IMPORTANT POINTS TO REMEMBER**

- 1. Hydrogen is the lightest element. Its atom consists of a single proton and a single planetary electron. Hydrogen is the only element whose atom does not have neutrons in its nucleus. It has the simplest electronic configuration,  $1s^1$ .
- Hydrogen was prepared by Cavendish in 1766 by the action of acids on metals. It was named 'inflammable air'. Lavoiser named it hydrogen (hydra = water, gennas = maker) meaning water maker.
- 3. Hydrogen is the most abundant element in the universe (70% of the universe's total mass). Sun and some other stars consist mostly of hydrogen. Free hydrogen is present in minute quantity in air, volcanic gases and natural gas. In the combined state, it constitutes 15.4% of the earth's crust and oceans as water, mineral oil, organic materials such as hydrocarbons, carbohydrates, fats, proteins, etc. Hydrogen is an essential constituent of all acids and alkalies.
- 4. Hydrogen shows dual nature. It behaves as electropositive element like alkali metals as it can lose the planetary electron. It also behaves as an electronegative element like halogens as it can gain one more electron to saturate 1s subshell. It is the first member in the periodic table but its position is not fixed. Sometimes, it is placed with alkali metals in IA subgroup and sometimes with halogens in VIIA (17th) subgroup.
- The atomic form of hydrogen exists only at high temperatures. Normal elemental hydrogen is the diatomic molecule, called dihydrogen, H<sub>2</sub>.
  - The ordinary hydrogen at room temperature is a mixture of ortho-form and para-form in the ratio of 3:1. The nuclei of ortho hydrogen spin in the same direction while that of the para hydrogen spin in the opposite directions.
- 6. Hydrogen exists in three isotopes. It is the only known element whose isotopes have the unique mass ratio of 1, 2, 3 (<sup>1</sup><sub>1</sub>H; <sup>2</sup><sub>1</sub>H; <sup>3</sup><sub>1</sub>H). The predominant form is <sup>1</sup><sub>1</sub>H (protium). <sup>2</sup><sub>1</sub>H or D (Deuterium) is present upto 0.0156% in terrestrial hydrogen, mostly in the form of HD. Tritium (Tor <sup>3</sup><sub>1</sub>H) is radioactive. It emits β-particles and its half life period is 12.33 years. The three isotopes have same chemical properties but their physical properties are different due to different atomic masses. Deuterium and tritium are used as tracers, bombarding projectiles especially in fusion reactions, i.e., in hydrogen bombs.
- There are three main sources from which dihydrogen (ordinary hydrogen) may be prepared. These are (i) Water, (ii) Acids and (iii) Alkalies.
  - (a) Alkali and alkaline earth metals react with cold water producing dihydrogen. The reactions are vigorous. To minimise the rate of reactions, usually amalgams are used.

- (b) Metals like Zn, Fe, Mn, Co, Cr, Sn, etc., decompose steam or hot water forming dihydrogen.
- (c) Reactions of steam on hydrocarbons or coke at high temperatures produce dihydrogen.

temperatures produce dinydrogen.

$$C_nH_{2n+2} + nH_2O \xrightarrow{1270 \text{ K}} nCO + (2n+1)H_2$$
 $C + H_2O \xrightarrow{\text{Cotalyst}} CO + H_2$ 

Water containing a small amount of acid or all

- (d) Water containing a small amount of acid or alkali on electrolysis in an electrolytic cell produces dihydrogen at cathode. The cathode used is usually of iron and anode usually of nickel. The two electrodes are separated by an asbestos diphragm.
- (e) Ionic hydrides on hydrolysis with water evolve dihydrogen.

$$CaH_2 + 2H_2O \longrightarrow Ca(OH)_2 + 2H_2$$
  
Hydrolith

- (f) The metals which occupy their position above hydrogen in the electrochemical series such as Zn, Al, Mg, Fe, etc., react with dil.HCl or dil. H<sub>2</sub>SO<sub>4</sub> to evolve dihydrogen. Mn and Mg react with dil. HNO<sub>3</sub> to evolve dihydrogen.
- (g) Zn, Al, Sn, Si, Pb react with boiling NaOH or KOH to evolve dihydrogen. Uyeno's method is used for military purposes for rapid and pure production of dihydrogen when scrap aluminium reacts with caustic potash.

$$2A1 + 2KOH + 2H_2O \longrightarrow 2KAlO_2 + 3H_2$$

- (h) Dihydrogen is produced in the laboratory by action of dilute H<sub>2</sub>SO<sub>4</sub> on granular zinc. The dihydrogen produced contains a number of impurities. To remove these impurities, the evolved dihydrogen is passed through three bottles containing AgNO<sub>3</sub> solution (removes PH<sub>3</sub> and AsH<sub>3</sub>), Pb(CH<sub>3</sub>COO)<sub>2</sub> solution (removes H<sub>2</sub>S) and KOH solution (removes CO<sub>2</sub>, SO<sub>2</sub> and oxides of nitrogen) respectively.
- (i) Pure dihydrogen is obtained either (i) by carrying electrolysis of barium hydroxide solution using platinum electrodes or nickel electrodes or (ii) by action of water on sodium hydride (NaH) or (iii) by Uyeno's method.
- 8. Large quantities of dihydrogen are required these days in industry for various purposes. About 77% of the industrial dihydrogen is produced from petro-chemicals, 18% from coal, 4% from electrolysis of aqueous solutions and 1% from other sources.

Natural gas mainly consists of methane. Dihydrogen is obtained from natural gas either by partial oxidation or cracking. Natural gas is mixed with steam and passed over a

catalyst (Ni-Cr alloy) at 1200 K. The CO is converted into CO<sub>2</sub> by passing the gases and steam over iron oxide or cobalt oxide catalyst at 750 K resulting in the generation of more H<sub>2</sub>.

$$CH_4 + H_2O \xrightarrow[Ni-Cr]{1200 \text{ K}} CO + 3H_2$$

$$CH_4 \xrightarrow{Cracking} C + 2H_2$$

$$CO + H_2O \xrightarrow[Fe_2O_3]{750 \text{ K}} CO_2 + H_2$$

(CO<sub>2</sub> is removed by dissolving it in water under pressure of about 25-30 atmosphere.)

Bosch's process is used to obtain dihydrogen from coke.

$$C + H_2O \xrightarrow{1273 \text{ K}} CO + H_2$$

- 9. Dihydrogen is a colourless, odourless and tasteless gas. Hydrogen has high heat of dissociation (436 kJ mol<sup>-1</sup>). This property is made use of in the atomic torch which generates temperatures of about 4000 K and is ideal for welding of metals of high melting points. It has low melting and boiling points. It is only slightly soluble in water. It is diatomic in nature and bond length is 74 pm.
- 10. Certain metals like palladium, platinum, iron, etc., can adsorb large quantities of hydrogen. The adsorbed hydrogen is called occluded hydrogen. This property can be used for the purification of hydrogen because only pure hydrogen is adsorbed.
- 11. Dihydrogen is inflammable or combustible gas. However, it does not help in burning. It burns with blue flame in oxygen atmosphere forming water. Dihydrogen is not a very active element and does not react readily with other elements. Under suitable conditions, it can be made to combine with metals and non-metals both. It forms compounds by losing, gaining or sharing of its only electron. It shows oxidation states of +1, 0 and -1. H<sub>2</sub> has great affinity for oxygen. Thus, it acts as a reducing agent. The oxides of less electropositive metals such as copper, tin, iron, lead, etc., are reduced to the metals when heated in hydrogen. Numerous substances are hydrogenated in presence of suitable catalysts.
- 12. Dihydrogen forms three types of hydrides: ionic, covalent and interstitial. Ionic or salt like (saline) hydrides are formed by alkali metals, alkaline earth metals with exception of Be and Mg and some highly electropositive members of lanthanide series. These are colourless crystalline compounds with electrovalent nature in which hydrogen acts as an anion. All ionic hydrides react with H<sub>2</sub>O to produce dihydrogen. Ionic hydrides are powerful reducing agents.

Covalent or molecular hydrides are formed by all the true nonmetals (except zero group elements) and the elements such as Al, Ga, Sn, Pb, Sb, Bi, Po, etc., which are normally metallic in nature, *i.e.*, *p*-block elements. In these hydrides, hydrogen atoms are covalently bonded to the central atom. The boiling points of the simple hydrides of first elements of group 15 (NH<sub>3</sub>), 16 (H<sub>2</sub>O) and 17 (H<sub>2</sub>F<sub>2</sub>) are abnormally high due to intermolecular hydrogen bonding. The boiling points of remaining hydrides within the group, however, increase regularly with increase in atomic number of the element. Metallic or interstitial hydrides are formed by many d-block and f-block elements at elevated temperatures. These hydrides are often non-stoichiometric and have metallic appearance. They possess reducing properties probably due to presence of free hydrogen. These hydrides are used for the ultrapurification of hydrogen and as hydrogen storage media.

- Complex metal hydrides such as LiAlH<sub>4</sub> and NaBH<sub>4</sub> are powerful reducing agents and are widely used in organic reactions.
- 14. Hydrogen has been considered as one of the alternate sources of energy. The advantage of using hydrogen as a fuel is that it is environmentally clean. The second advantage with hydrogen is that the heat of combustion of hydrogen per gram is higher than any other fuel. Our energy needs can be met by gaseous, liquid and solid hydrogen. However, cheaper methods of production of hydrogen are to be developed and problems in storing and transportation are to be tackled.
- 15. Dihydrogen has following industrial applications:
  - (a) Synthesis of ammonia
  - (b) Manufacture of methyl alcohol
  - (c) Hydrogenation of oils
  - (d) Manufacture of hydrogen chloride
  - (e) Production of synthetic petrol
  - (f) Oxy-hydrogen flame
  - (g) Fuel for rockets
  - (h) With helium, it is used for filling balloons employed for atmospheric study
- 16. Water is most common and abundant compound of hydrogen. Water occupies the major part of the earth. It is essential to life. Two-third of human body is water. Water has the ability to dissolve a number of substances. Water has unique properties. Its transformation from liquid to solid and to gaseous states is easy. Water exists as a liquid under normal atmospheric conditions. It exists as a solid below 0°C and as a gas above 100°C. The unique properties in the liquid and solid phase are a result of extensive hydrogen bonding between water molecules. Water molecule forms four H-bonds. Water has a higher specific heat, thermal conductivity and surface tension than most of the other liquids. Because of these properties water plays an important role in the biosphere. The density of water is maximum at 4°C.
- 17. Pure water is colourless, tasteless and odourless. It is neutral in nature, pH of pure water is 7. It reacts with active metals when hydrogen is evolved. It is decomposed by metals like Zn, Mg, Fe, etc., when steam is passed over hot metals. Fluorine decomposes water forming ozonised oxygen. Chlorine decomposes water in presence of sunlight. Acidic oxides combine with water to form oxy-acids while basic oxides form alkalies. Water decomposes a number of hydrides, carbides, nitrides, phosphides with liberation of hydrogen, acetylene (or methane), ammonia, phosphine, respectively. Water forms hydrates of different types.
- 18. Oxygen atom in water molecule is sp<sup>3</sup> hybridized, four hybrid orbitals directed towards the corners of a tetrahedron are formed. Two of the hybrid orbitals having one electron each overlap with hydrogen atoms and form two sigma bonds. Thus, the molecule has a bent (V-shaped) structure with a

bond angle of 104.5°. The bond angle is less than the expected due to presence of two lone pairs of electrons on two uncombined hybrid orbitals. The molecule is polar due to difference in the electronegativities of hydrogen and oxygen and possesses dipole moment. Water molecules are linked with each other by hydrogen bonding.

- 19. Ice has open cage like structure with a number of vacant spaces in the crystal lattice. As a result, the density of ice is lower than that of water.
- 20. Water is tested by the following tests:
  - (i) A drop of water when added to anhydrous copper sulphate, change its colour from white to blue.
  - (ii) Water reacts with calcium carbide to evolve acetylene which burns with bright flame.
- 21. Water is said to be soft if it produces sufficient lather with soap. Hard water does not form lather readily with soap as it forms an insoluble scum. Hardness of water is of two types:
  - (i) **Temporary:** This is due to presence of bicarbonates of calcium and magnesium. It can be easily removed by boiling or by adding slaked lime.
  - (ii) Permanent: It is caused by the presence of chlorides and sulphates of calcium and magnesium. Many substances can be used for the removal of permanent hardness. Those are termed water softeners. The various water softeners are:
    - (i) Washing soda (ii) Permutit—hydrated silicates of aluminium and sodium (Na<sub>2</sub>Al<sub>2</sub>Si<sub>2</sub>O<sub>8</sub>·XH<sub>2</sub>O) (iii) Calgon-sodium hexa-meta-phosphate (NaPO<sub>3</sub>)<sub>6</sub> (iv) Ion-exchange resins.
- 22. Degree of hardness is defined as the number of parts of calcium carbonate or equivalent to calcium and magnesium salts present in million parts of water by mass. It is expressed in ppm.
- 23. Heavy water (D<sub>2</sub>O) was discovered by Urey. One part of heavy water is present in 6000 parts of ordinary water. It is obtained by repeated electrolysis of water containing alkali. Like ordinary water, it is also colourless, odourless and tasteless. Nearly all the physical constants are higher than the corresponding values of ordinary water. It is used as a moderator in nuclear reactors.
- 24. Hydrogen peroxide was discovered by Thenard on treating barium peroxide with sulphuric acid. It was called oxygenated water.
- **25.** H<sub>2</sub>O<sub>2</sub> is prepared by adding ice cold dilute H<sub>2</sub>SO<sub>4</sub>(20%) on Na<sub>2</sub>O<sub>2</sub> or BaO<sub>2</sub>. As H<sub>2</sub>SO<sub>4</sub> catalyses the decomposition, some weaker acids such as H<sub>3</sub>PO<sub>4</sub> or H<sub>2</sub>CO<sub>3</sub> (H<sub>2</sub>O + CO<sub>2</sub>) are preferred.
- **26.** Manufacture of H<sub>2</sub>O<sub>2</sub> is done by following methods:
  - (i) Auto-oxidation of 2-butyl anthraquinol. It is the most recent method. 2-butyl anthraquinone is catalytically reduced to 2-butyl anthraquinol in an organic solvent in presence of palladium by passing hydrogen. It is then oxidised by passing air. The H<sub>2</sub>O<sub>2</sub> is extracted with water to give a 20% solution. 2-butyl anthraquinone is reformed which is again used.
  - (ii) By oxidation of isopropyl alcohol: The isopropyl alcohol is mixed with a small amount of H<sub>2</sub>O<sub>2</sub> and oxygen is passed at 70°C. Acetone and unreacted

- alcohol distil over leaving behind the aqueous solution of  $H_2O_2$ .
- (iii) Electrolytic process: 50% H<sub>2</sub>SO<sub>4</sub> solution or equimolar mixture of H<sub>2</sub>SO<sub>4</sub> and (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> is electrolysed at low temperature using platinum electrodes and a current of high density. Peroxy disulphuric acid (H<sub>2</sub>S<sub>2</sub>O<sub>8</sub>) or ammonium peroxy disulphate is formed which on hydrolysis gives H<sub>2</sub>O<sub>2</sub> solution.
- 27. H<sub>2</sub>O<sub>2</sub> is stored in the vessels of pure aluminium or in stone jars in dark. Concentrated solutions of H<sub>2</sub>O<sub>2</sub> are stored these days in polythene bottles kept in refrigerators. Small amounts of stabilizers such as orthophosphoric acid acetanilide or sodium stannate are added.
- **28.** Pure H<sub>2</sub>O<sub>2</sub> is a syrupy liquid. It is soluble in water, alcohol and ether. Its specific gravity is 1.45. It is injurious to skin. It has bitter taste. Hydrogen bonding is present, thus it is an associated liquid.
- 29. It decomposes on standing and heating. Presence of traces of MnO<sub>2</sub>, carbon, alkali or finely divided metals like Pt, Au, Ag, etc., accelerate its decomposition. The pure liquid-has-weak acidic nature.  $K_a = 1.55 \times 10^{-12}$ . It is less acidic than carbonic acid, i.e.,  $H_2CO_3 > H_2O_2 > H_2O$ . It acts as an oxidising agent as well as a reducing agent both in the acidic as well as in the basic medium.

$$\begin{aligned} & \text{Oxidising nature} \begin{cases} \text{H}_2\text{O}_2 + 2\text{H}^+ + 2e & \longrightarrow 2\text{H}_2\text{O} \text{ (In acidic medium)} \\ \text{H}_2\text{O}_2 + 2e & \longrightarrow 2\text{OH}^- \text{ (In alkaline medium)} \end{cases} \\ & \text{Reducing nature} \begin{cases} \text{H}_2\text{O}_2 & \longrightarrow 2\text{H}^+ + \text{O}_2 + 2e \\ & \text{ (In acidic medium)} \end{cases} \\ & \text{H}_2\text{O}_2 + 2\text{OH}^- & \longrightarrow 2\text{H}_2\text{O} + \text{O}_2 + 2e \\ & \text{ (In alkaline medium)} \end{cases}$$

**30.** H<sub>2</sub>O<sub>2</sub> acts as a bleaching agent for delicate articles like hair, silk, wool, ivory, etc. The bleaching action is due to oxidation by nascent oxygen and hence is permanent.

$$H_2O_2 \longrightarrow H_2O + [O]$$

- **31.** H<sub>2</sub>O<sub>2</sub> is a valuable antiseptic and germicide for washing wounds teeth and ears under the name **perhydrol**. It is used for restoring colour of old paintings as it oxidises black PbS to PbSO<sub>4</sub>. Highly concentrated solutions (about 40%) of H<sub>2</sub>O<sub>2</sub> are used to oxidise petrol, alcohol, hydrazine hydrate for the propelling rockets and torpedoes.
- 32. X-ray measurements show that bond distance between O—O is  $1.46 \pm 0.03$  Å. The value of dipole moment is 2.1D. This suggests that  $H_2O_2$  molecule is a non-linear molecule. In gas phase, the molecule can be pictured as lying on the spine of the book open to an angle of  $111.5^{\circ}$ . The hydrogen atoms are present on each cover and  $\angle OOH = 94.8^{\circ}$ .
- **33.** Strength of the sample of hydrogen peroxide is generally expressed in terms of volume of oxygen at NTP that one volume of hydrogen peroxide on heating gives. The commercial samples are marked as '10 volume', '15 volume' or '20 volume'. '10 volume' solution means that one volume of H<sub>2</sub>O<sub>2</sub> gives 10 volume of oxygen at NTP on decomposition. Sometimes the concentration of H<sub>2</sub>O<sub>2</sub> is expressed as percentage of H<sub>2</sub>O<sub>2</sub> in solution, *i.e.*, g/100 mL. 30% hydrogen

peroxide means that 30 grams of H<sub>2</sub>O<sub>2</sub> is present in 100 mL of solution.

'10 volume' solution of  $H_2O_2$  is 3.035% solution. Strength of '10 volume'  $H_2O_2$  solution is 30.35 g/litre. Normality of '10 volume'  $H_2O_2$  solution = 1.785 *i.e.*, Volume strength =  $5.6 \times Normality$ Similarly Volume strength =  $11.2 \times Molarity$ .

 $1M H_2O_2 = 2N H_2O_2 = 11.2 \text{ volume } H_2O_2 = 3.4\%$ 

# ••- PRACTICE PROBLEMS -

#### **■** Subjective Type Questions

#### 1. Answer the following:

- (a) Which isotope of hydrogen contains equal number of protons and neutrons?
- (b) What is Syn. gas?
- (c) Name two complex metal hydrides which are used as reducing agents in organic reactions.
- (d) What is hydride gap?
- (e) What is autoprotolysis of water?
- (f) What common compounds of hydrogen are more powerful reducing agents than hydrogen itself?
- 2. (a) Which is heavier, ice or water?
  - (b) What is deionised water? Can distilled water be called as deionised water?
  - (c) What name is given to a water softener, sodium polymetaphosphate?
  - (d) What gases are evolved when the following react with water?
    - (i)  $Mg_3N_2$  (ii)  $CaC_2$  (iii)  $Ca_3P_2$
- 3. (a) Give three characteristics in which hydrogen resembles halogens.
  - (c) Give three characteristics in which hydrogen resembles alkali metals.
  - (c) Give four industrial uses of hydrogen.

#### 4. Answer the following:

- (i) In which group of the periodic table, hydrogen is placed?
- (ii) Which metals react with H<sub>2</sub>O or dilute HCl or dilute H<sub>2</sub>SO<sub>4</sub> to evolve hydrogen?
- (iii) Very pure hydrogen is obtained with rapidity by the action of caustic potash on scrap aluminium. What is the name of this method?
- (iv) Which zinc (pure or commercial) is used for the preparation of hydrogen in laboratory?
- (v) Which solution is used for the removal of AsH<sub>3</sub> and PH<sub>3</sub> present in very small amounts in hydrogen sample?
- (vi) How is hydrogen obtained from natural gas?
- (vii) What type of hydrides are formed by the elements having low electronegativity?
- (viii) What is the temperature of oxy-hydrogen flame?
- (ix) What is percentage of ortho form in ordinary hydrogen at room temperature?
- (x) Which form of hydrogen is used for welding purposes?
- (xi) Which isotope of hydrogen is radioactive in nature?
- (xii) What is the use of heavy water in nuclear reactors?

- (xiii) What is the difference between the rates of reactions of D<sub>2</sub>O and H<sub>2</sub>O<sub>2</sub>?
- (xiv) How heavy water is obtained from ordinary water?
- (xv) Why has D<sub>2</sub>O more density than H<sub>2</sub>O?
- (xvi) What chemical change does occur when temporary hard water is boiled?
- (xvii) What is calgon?
- (xviii) What type of overlapping of orbitals occur in the formation of peroxo linkage (—O—O—) in H<sub>2</sub>O<sub>2</sub> molecule?
- (xix) Name the chemical compound used in the preparation of H<sub>2</sub>O<sub>2</sub> by auto-oxidation.
- (xx) Name the blue coloured compound formed in the reaction of H<sub>2</sub>O<sub>2</sub> with acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in ether.
- (xxi) How H<sub>2</sub>O<sub>2</sub> acts as an antiseptic?
- (xxii) What volume of oxygen at NTP is obtained from 10 mL of 10 volume H<sub>2</sub>O<sub>2</sub>?
- (xxiii) What is the principle in bleaching action of H<sub>2</sub>O<sub>2</sub>?
- (xxiv) How is concentration of H<sub>2</sub>O<sub>2</sub> done?
- (xxv) Which acts as an oxidising agent in the reaction of H<sub>2</sub>O<sub>2</sub> and O<sub>3</sub>?

#### 5. What happens when?

- (a) An alkaline solution of potassium ferricyanide is treated with hydrogen peroxide. [I.I.T. 1989]
- (b) Chromium hydroxide is treated with hydrogen peroxide in the presence of NaOH. [M.L.N.R. 1992]
- (c) Concentrated solution of NH<sub>4</sub>HSO<sub>4</sub> in H<sub>2</sub>SO<sub>4</sub> is electrolysed using current of high density.
- (d) Hydrazine reacts with hydrogen peroxide.
- (e) Benzene is treated with H<sub>2</sub>O<sub>2</sub> in presence of FeSO<sub>4</sub>.
- (f) Lactic acid is treated with Fenton's reagent.
- (g) Tin tetrahalide is treated with lithium aluminium hydride.
- (h) Sodium hydride reacts with diborane.
- (i) Hydrogen peroxide reacts with Ba(OH)<sub>2</sub>.
- (j) Sodium hypochlorite reacts with H<sub>2</sub>O<sub>2</sub>.
- (i) Give two reactions in each case to show that H<sub>2</sub>O<sub>2</sub> behaves as,
  - (a) an acid, (b) a reducing agent, (c) an oxidising agent.
  - (ii) Mention one catalyst in each case.
    - (a) Which retards H<sub>2</sub>O<sub>2</sub> decomposition.
    - (b) Which accelerates H<sub>2</sub>O<sub>2</sub> decomposition.
- 7. (i) Name the isotopes of hydrogen.
  - (ii) How many protons, neutrons and electrons are present in the isotopes of hydrogen?
  - (iii) What is the molecular mass of heavy water? Give one chemical reaction only for the preparation of deuterium from heavy water.

- (iv) Give two uses of heavy water.
- (v) Write two important uses of heavy hydrogen.
- (vi) How many different combinations of water are possible from 1H<sup>1</sup>, 1H<sup>2</sup>, 1H<sup>3</sup> and 8O<sup>16</sup>, 8O<sup>17</sup> and 8O<sup>18</sup>?
- (vii) How does heavy water react with the following?
  - (a) CaC<sub>2</sub>
- (b)  $Mg_3N_2$
- (c)  $P_2O_5$
- (d) H<sub>2</sub>SO<sub>4</sub>

#### 8. Write short notes on:

- (i) Nascent hydrogen
- (ii) Atomic hydrogen
- (iii) Ortho- and para- hydrogen
- (iv) Bosch's process
- (v) Lane's process
- (vi) Calgon
- (vii) Permutit method of softening water
- (viii) Ion-exchange method for removal of hardness of water
- (ix) Industrial applications of hydrogen
- (x) Strength of hydrogen peroxide
- (xi) Zeolite

#### 9. Explain the following:

- (i) Why are the melting and boiling points of D<sub>2</sub>O are higher than those of ordinary water?
- (ii) Presence of water is avoided in the preparation of H<sub>2</sub>O<sub>2</sub> from Na<sub>2</sub>O<sub>2</sub>.
- (iii) A mixture of hydrazine and H<sub>2</sub>O<sub>2</sub> is used as a rocketpropellant.
- (iv) Hydrogen peroxide acts as an oxidising agent as well as a reducing agent. [I.I.T. 1992]
- (v) Hydrogen peroxide gives acidic properties.
- 10. The following statements are true under certain conditions. Mention the condition in each case in a few words.
  - (i) Hydrogen reacts with oxygen to form water.
  - (ii) Hydrogen reacts with nitrogen to form ammonia.
  - (iii) Hydrogen can be prepared from water at ordinary temperatures.
  - (iv) A metal will liberate hydrogen by its reaction with dil. H<sub>2</sub>SO<sub>4</sub>.
  - (v) The unsaturated hydrocarbon, ethylene, is saturated to ethane by hydrogen.

#### Matching Type Questions

#### Match the following:

- (a) Manufacture of Hydrogen
- (b) Ionic hydride
- (c) Preparation of H<sub>2</sub>O<sub>2</sub>
- (d) Electron deficient hydride
- (e) Hard water
- (f) Heavy water
- (g) Permutit
- (h) Perhydrol

- (i) Boron hydride
- Oxide of heavy hydrogen
- (iii) Antiseptic and germicide
- (iv) An artificial zeolite
- (v) Mercks' process
- (vi) Bosch's process
- (vii) Hydrolith
- (viii) Scale in boilers

#### NUMERICAL PROBLEMS

1. What mass of CaO will be required to remove the hardness of 1000 litres of water containing 1.62 g of calcium bicarbonate per litre?

[Hint: 
$$Ca(HCO_3)_2 + CaO \longrightarrow 2CaCO_3 + H_2O + CO_2$$
]  
162 g 56 g

[Ans.  $5.6 \times 10^2$  g]

2. 100 mL of tap water containing Ca(HCO<sub>3</sub>)<sub>2</sub> was titrated with N/50 HCl with methyl orange as indicator. If 30 mL of HCl were required, calculate the temporary hardness as parts of CaCO<sub>3</sub> per 10<sup>6</sup> parts of water.

[Hint: 30 mL N/50 HCl = 30 mL N/50 Ca(HCO<sub>3</sub>)<sub>2</sub>

 $\equiv$  30 mL N/50 CaCO<sub>3</sub>  $\equiv$  100 mL tap water

Mass of CaCO<sub>3</sub> in 100 mL tap water = 
$$\frac{E \times N \times V}{1000}$$
$$= \frac{50 \times 30}{50 \times 1000} = 0.03 \text{ g}$$

[Ans. Hardness = 300 ppm]

3. 20 mL of H<sub>2</sub>O<sub>2</sub> after acidification with dilute H<sub>2</sub>SO<sub>4</sub> required 30 mL of N/12 KMnO<sub>4</sub> for complete oxidation. Calculate the percentage of H2O2 in the solution. Equivalent mass of  $H_2O_2 = 17$ .

[Hint: 30 mL 
$$\frac{N}{12}$$
 KMnO<sub>4</sub> = 20 mL  $N_x$ H<sub>2</sub>O<sub>2</sub>  
Normality of H<sub>2</sub>O<sub>2</sub> soln.,  $N_x = \frac{30}{12 \times 20} = \frac{1}{8}$   
Strength = Normality × Eq. mass =  $\frac{1}{8}$  × 17 = 2.125 gL<sup>-1</sup>  
% =  $\frac{2.125}{1000}$  × 100 = 0.2125

4. 25 mL of hydrogen peroxide solution were added to excess of acidified potassium iodide solution. The iodine so liberated required 20 mL of 0.1 N sodium thiosulphate solution. Calculate strength in terms of normality, percentage and volume.

[M.L.N.R. 1996]

[M.L.N.R. 19]
[Hint: Let the normality of 
$$H_2O_2$$
 soln. be  $N_x$ .

20 mL 0.1  $N$  Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 20% mL 0.1  $N$  I<sub>2</sub>
= 25 mL  $N_x$  H<sub>2</sub>O<sub>2</sub>

Normality of  $H_2O_2$ ,  $N_x = \frac{20 \times 0.1}{25} = \frac{2}{25} = 0.08$ 

Strength = Eq. mass × normality
= 17 × 0.08 = 1.36 gL<sup>-1</sup>

Percentage = 0.136

68 g H<sub>2</sub>O<sub>2</sub> give oxygen at NTP = 22400 mL

0.00136 g H<sub>2</sub>O<sub>2</sub> give oxygen at NTP =  $\frac{22400}{68} \times 0.00136$ 
= 0.448 mL

1 mL of H<sub>2</sub>O<sub>2</sub> solution gives 0.448 mL oxygen.]

5. What is the volume strength of a molar solution of hydrogen peroxide?

[Hint: 1 molar solution consists 34 g H<sub>2</sub>O<sub>2</sub> per litre.] [Ans. 11.2 volume]

 Calculate the mass of H<sub>2</sub>O<sub>2</sub> present in 600 mL of a 10 volume hydrogen peroxide solution.

[Ans. 18.2 g]

 10.2 g of pure H<sub>2</sub>O<sub>2</sub> are heated strongly till completely decomposed. Calculate the volume of oxygen evolved at 27°C and 740 mm pressure.

[Ans. 3792 mL]

**8.** Calculate the volume strength of a 5 N hydrogen peroxide solution.

[**Hint**: 5 N solution consists 85 g  $H_2O_2$  per litre.] [**Ans.** 28 volume]

9. There is a sample of 10 volume of hydrogen peroxide solution. Calculate its strength in (i) per cent of hydrogen peroxide and (ii) grams of H<sub>2</sub>O<sub>2</sub> per litre.

[Ans. 3.035%, 30.35 gL<sup>-1</sup>]

[M.L.N.R. 1990]

## Auswers

#### Answers: Subjective Type Questions

- 1. (a) Deuterium
  - (b) It is a mixture of CO and H<sub>2</sub>.
  - (c) LiAlH<sub>4</sub> and NaBH<sub>4</sub>.
  - (d) Elements of groups 7, 8 and 9 do not form hydrides and even the elements of group 6 except chromium do not form hydride. This region of periodic table from group 6 to 9 is termed hydride gap.
  - (e) Autoprotolysis of water means self ionisation of water.

$$H_2O + H_2O \Longrightarrow H_3O^+ + OH^-$$

- (f) The saline hydrides
- 2. (a) Water (b) Water free from all types of cations and anions is called deionised water. Yes.
  - (c) Calgon (d) (i)  $NH_3$  (ii)  $C_2H_2$  (iii)  $PH_3$
- 4. (i) No fixed position, sometimes placed in IA with alkali metals and sometimes in VIIA (or 17th) group with halogens.
  - (ii) Metals having positive oxidation potential values or placed above hydrogen in the electrochemical series evolve hydrogen with water or dilute HCl or dilute H<sub>2</sub>SO<sub>4</sub>.
  - (iii) Uyeno method,

$$2A1 + 2KOH + 2H_2O \longrightarrow 2KAlO_2 + 3H_2\uparrow$$

- (iv) Commercial zinc.
- (v) AgNO<sub>3</sub> solution.
- (vi) Either by partial oxidation or cracking.
- (vii) Ionic hydrides.
- (viii) 2800°C.
- (ix) 75.
- (x) Atomic hydrogen.
- (xi) Tritium.
- (xii) Heavy water is used as a moderator. It slows down the speed of fast neutrons.
- (xiii) The rates of reactions of D2O are slower than H2O.
- (xiv) By exhaustive electrolysis of ordinary water.
- (xv) The density of heavy hydrogen is twice that of hydrogen, hence the density of D<sub>2</sub>O is more than H<sub>2</sub>O.
- (xvi) Bicarbonates of Ca and Mg (soluble) are converted into insoluble carbonates.

$$Ca(HCO_3)_2 \longrightarrow CaCO_3 + H_2O + CO_2$$

- (xvii) It is a complex salt used as water softener. It's chemical name is sodium hexametaphosphate, Na<sub>2</sub>[Na<sub>4</sub>(PO<sub>3</sub>)<sub>6</sub>].
- (xviii) p-p overlapping.
- (xix) Anthraquinone.
- (xx) CrO<sub>5</sub>, chromium peroxide,

$$K_2Cr_2O_7 + 4H_2O_2 + H_2SO_4 \xrightarrow{Ether} K_2SO_4 + 2CrO_5 + 5H_2O$$

(xxi) H2O2 gives nascent oxygen that kills bacteria.

- (xxii) 100 mL.
- (xxiii) Oxidising nature.
- (xxiv) Concentration is done by vacuum distillation.
- (xxv)  $O_3$  acts as an oxidising agent while  $H_2O_2$  acts as a reducing agent,  $H_2O_2 + O(given by O_3) \longrightarrow H_2O + O_2$ .
- 5. (a) Potassium ferricyanide is reduced.

$$2K_3Fe(CN)_6 + 2KOH + H_2O_2 \longrightarrow 2K_4Fe(CN)_6 + 2H_2O + O_2$$

(b)  $Cr(OH)_3$  is converted into yellow coloured  $Na_2CrO_4$ .  $2Cr(OH)_3 + 4NaOH + 3H_2O_2 \longrightarrow 2Na_2CrO_4 + 8H_2O$ 

(c)  $NH_4HSO_4 \rightleftharpoons H^+ + NH_4SO_4^-$ 

At anode : 
$$2NH_4SO_4^- \longrightarrow (NH_4)_2S_2O_8 + 2e^-$$
  
Ammonium

peroxydisulphate

At cathode:  $2H^+ + 2e^- \longrightarrow H_2(g)$ (d) Hydrazine is oxidised to  $N_2$  and  $H_2O$ 

$$N_2H_4 + 2H_2O_2 \longrightarrow N_2 + 4H_2O$$

(e) Benzene in presence of FeSO<sub>4</sub> is converted into phenol.

$$C_6H_6 + H_2O_2 \longrightarrow C_6H_5OH + H_2O$$

(f) Lactic acid is oxidised to pyruvic acid

CH<sub>3</sub>CHOHCOOH + H<sub>2</sub>O<sub>2</sub> 
$$\xrightarrow{\text{FeSO}_4}$$
 CH<sub>3</sub>COCOOH + 2H<sub>2</sub>O

(g) Tin hydride is formed.

(h) Sodium borohydride is formed.

$$B_2H_6 + 2NaH \longrightarrow 2NaBH_4$$

(i) 
$$H_2O_2 + Ba(OH)_2 \longrightarrow BaO_2 + 2H_2O$$

(j) NaOCl + 
$$H_2O_2 \longrightarrow NaCl + H_2O + O_2$$

6. (i) (a) 
$$Na_2CO_3 + H_2O_2 \longrightarrow Na_2O_2 + H_2O + CO_2$$
  
 $2NaOH + H_2O_2 \longrightarrow Na_2O_2 + 2H_2O$ 

$$O_3 + H_2O_2 \longrightarrow 2O_2 + H_2O$$

$$Ag_2O + H_2O_2 \longrightarrow 2Ag + H_2O + O_2$$

(c) 
$$H_2S + H_2O_2 \longrightarrow S + 2H_2O$$

$$PbS + 4H_2O_2 \longrightarrow PbSO_4 + 4H_2O$$

- (ii) The decomposition of H<sub>2</sub>O<sub>2</sub> is retarded by orthophosphoric acid while it is accelerated by presence of alkali or finely divided metals like Pt, Ag, Au, etc.
- 7. (i) Three isotopes (a) Protium (b) Deuterium (c) Tritium
- (ii) 1 proton 1 proton 1 proton
  1 electron 1 electron 1 electron
  no neutron 1 neutron 2 neutrons
  - (iii) 20; 3Fe + 4D<sub>2</sub>O  $\longrightarrow$  Fe<sub>3</sub>O<sub>4</sub> + 4D<sub>2</sub>
  - (iv) (a) As a moderator (b) for the production of deutero compounds.
  - (v) (a) For tracer studies (b) for fusion reactions.
  - (vi) 18

(b)

(vii) (a) 
$$CaC_2 + 2D_2O \longrightarrow Ca(OD)_2 + C_2D_2$$

(b) 
$$Mg_3N_2 + 6D_2O \longrightarrow 3Mg(OD)_2 + 2ND_3$$

(c) 
$$P_2O_5 + 3D_2O \longrightarrow 2D_3PO_4$$

(d) 
$$H_2SO_4 + D_2O \longrightarrow D_2SO_4 + H_2O$$

- 9. (i) D<sub>2</sub>O has more molecular mass and greater degree of association than H<sub>2</sub>O and thus shows higher m.pt. and b.pt.
  - (ii) Water reacts with Na2O2 to produce NaOH which increases the decomposition of H<sub>2</sub>O<sub>2</sub>.
  - (iii) The reaction is highly exothermic. It brings large increase in volume also.

$$N_2H_4 + 2H_2O_2 \longrightarrow N_2(g) + 4H_2O(g)$$

(iv) This is due to the following reactions.

Oxidising agent:

$$H_2O_2 + 2H^+ + 2e^- \longrightarrow 2H_2O$$
 (acidic medium)  
 $H_2O_2 + 2e^- \longrightarrow 2OH^-$  (alkaline medium)

Reducing agent:

$$H_2O_2 \longrightarrow 2H^+ + O_2 + 2e^-$$

(v) H<sub>2</sub>O<sub>2</sub> reacts with bases to form peroxides (salts) and water

$$2NaOH + H_2O_2 \longrightarrow Na_2O_2 + 2H_2O$$

$$Ba(OH)_2 + H_2O_2 \longrightarrow BaO_2 + 2H_2O$$

(i) On electrical sparking; (ii) At elevated temperature (500-550°C) and high pressure (200 atm.) in presence of a catalyst; (iii) By electrolysis or by the action of some metal like sodium in the form of amalgam; (iv) Provided the position of the metal is above hydrogen in the electrochemical series; (v) In the presence of a catalyst at elevated temperatures.

Answers: Matching Type Questions

## ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. An inorganic substance liberates oxygen on heating and turns an acidic solution of KI brown and reduces acidified KMnO<sub>4</sub> solution. The substance is:
  - (a) HgO

- (b) H<sub>2</sub>O<sub>2</sub>
- (c) KNO<sub>3</sub>
- (d)  $Pb(NO_3)_2$

Ans. (b)

[Hint: 
$$2H_2O_2 \xrightarrow{\text{Heat}} 2H_2O + O_2$$
;

$$2KI + H_2O_2 \xrightarrow{\text{Acidic}} 2KOH + I_2$$
;

Acidified KMnO<sub>4</sub> acts as an oxidising agent when it is decolourised,  $H_2O_2 + O \longrightarrow H_2O + O_2$ .]

- 2. The volume strength of  $10 N H_2O_2$  is :
  - (a) 112

(b) 11.2

(c) 0.112

(d) 56

Ans. (d)

**[Hint:** Volume strength =  $5.6 \times$  normality]

- 3. In which of the properties listed below, hydrogen does not show similarity with halogens?
  - I. Nature of the oxide
  - II. Electropositive character
  - III. Combination with alkali metals
  - IV. Atomicity
  - (a) I and II (b) III and IV (c) II only (d) I and III Ans. (a)

[Hint: Hydrogen forms a neutral oxide, i.e., H<sub>2</sub>O (water) while the oxides of halogens are acidic. Hydrogen shows electropositive nature also while halogens are mostly electronegative in nature.]

- In which of the following reactions does hydrogen act as an oxidising agent?
  - (a)  $H_2 + F_2 \longrightarrow$
- (b)  $H_2 + SiCl_4 \longrightarrow$
- (c) Na +  $H_2 \longrightarrow$
- (d)  $CuO + H_2 \longrightarrow$

Ans. (c)

- [Hint: The reaction in which hydrogen accepts the electron or its oxidation number changes from 0 to -1, it acts as an oxidising agent.  $2Na + H_2 \longrightarrow 2Na^+ H^-$ .]
- 5. When H<sub>2</sub>O<sub>2</sub> is added to ice cold solution of acidified potassium dichromate in ether and the contents are shaken and allowed to stand:
  - (a) a blue colour is obtained in ether due to formation of Cr<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>.
  - (b) a blue colour is obtained in ether due to formation of CrOs.
  - (c) a blue colour is obtained in ether due to formation of
  - (d) chromyl chloride is formed.

Ans. (b)

Ans. (b) [Hint: 
$$Cr_2O_7^{2-} + 2H^+ + 4H_2O_2 \longrightarrow 2CrO_5 + 5H_2O$$
]

Blue colour in ether

- 6. Mass percentage of deuterium in heavy water is:
  - (a) same as that of protium in water
  - (b) 11.1
  - (c) 20.0

(d) cannot be predicted

Ans. (c)

[Hint: The formula of heavy water is D<sub>2</sub>O, i.e., molecular mass

% of deuterium = 
$$\frac{4}{20} \times 100 = 20$$
 ]

- 7. 2 g of aluminium is treated separately with excess of dilute H<sub>2</sub>SO<sub>4</sub> and excess of NaOH. The ratio of volumes of hydrogen evolved under similar conditions of pressure and temperature
  - (a) 2:3(b) 1:1
- (c) 2:1
- (d) 1:2

Ans. (b)

[Hint: 
$$2Al + 3H_2SO_4 \longrightarrow Al_2(SO_4)_3 + 3H_2$$
;

$$2Al + 2NaOH + 2H_2O \longrightarrow 2NaAlO_2 + 3H_2$$

Thus, ratio of volumes of hydrogen evolved is 1:1]

- 8. In which reaction, hydrogen peroxide neither acts as an oxidising agent nor as a reducing agent?
  - (a) PbS +  $H_2O_2 \longrightarrow$
- (b)  $SO_3^- + H_2O_2 \longrightarrow$
- (c)  $PbO_2 + H_2O_2 \longrightarrow$
- (d)  $Na_2CO_3 + H_2O_2 \longrightarrow$

Ans. (d)

[Hint: H<sub>2</sub>O<sub>2</sub> behaves as an acid when reacts with Na<sub>2</sub>CO<sub>3</sub>.

$$Na_2CO_3 + H_2O_2 \longrightarrow Na_2O_2 + CO_2 + H_2O]$$

- 9. Which one of the following reactions does not form gaseous product?
  - (a)  $PbO_2 + H_2O_2 \longrightarrow$
- (b) PbS +  $H_2O_2 \longrightarrow$
- (c)  $Cl_2 + H_2O_2 \longrightarrow$
- (d)  $Na_2CO_3 + H_2O_2 \longrightarrow$

[Hint: PbS +  $4H_2O_2 \longrightarrow PbSO_4 + 4H_2O$ ]

- 10. What is the degree of hardness of a sample of water containing 24 mg of MgSO<sub>4</sub> (molecular mass 120) per kg of water?
  - Ans. (c)
  - (c) 20 ppm (a) 10 ppm (b) 15 ppm

[Hint: 24 mg of MgSO<sub>4</sub> present in 10<sup>3</sup>g of water

 $10^6$ g water will contain = 24000 mg of MgSO<sub>4</sub> = 24 g of MgSO<sub>4</sub>

 $120 \text{ g of MgSO}_4 \equiv 100 \text{ g of CaCO}_3$ 

So, 24 g of MgSO<sub>4</sub> = 
$$\frac{100}{120} \times 24 = 20$$
 g of CaCO<sub>3</sub>

Hardness of water = 20 ppm]

- 11. In alkaline medium, H<sub>2</sub>O<sub>2</sub> reacts with Fe<sup>3+</sup> and Mn<sup>2+</sup>  $\label{eq:continuous} \begin{tabular}{ll} [J.E.E.~(Orissa)~2006] \\ (b)~Fe^{2+}~and~Mn^{2+} \end{tabular}$ separately to give:
  - (a) Fe<sup>4+</sup> and Mn<sup>4+</sup>
- (c) Fe<sup>2+</sup> and Mn<sup>4+</sup>
- (d) Fe<sup>4+</sup> and Mn<sup>2+</sup>

Ans. (c)

[Hint: K<sub>3</sub>Fe(CN)<sub>6</sub> is reduced by H<sub>2</sub>O<sub>2</sub> in alkaline medium.

$$2K_3Fe(CN)_6 + 2KOH + H_2O_2 \longrightarrow 2K_4Fe(CN)_6 + 2H_2O + O_2$$

 $Mn(OH)_2$  is oxidised by  $H_2O_2$  in alkaline medium.  $Mn(OH)_2 + H_2O_2 \longrightarrow MnO_2 + 2H_2O]$ 

- 12. When a substance A reacts with water, it produces a combustible gas B and a solution of substance C in water. D reacts with this solution of C and produces the same gas B on warming. D can also produce gas B on reaction with dilute H<sub>2</sub>SO<sub>4</sub>. A imparts a deep golden yellow colour to smokeless flame. A, B, C and D respectively are:
  - (a) Na, H<sub>2</sub>, NaOH, Zn
- (b)  $K, H_2, KOH, Al$
- (c) Ca, H<sub>2</sub>, Ca(OH)<sub>2</sub>, Sn
- (d)  $CaC_2$ ,  $C_2H_2$ ,  $Ca(OH)_2$ , Fe

Ans. (a) [Hint:

- 13. Polyphosphates are used as water softening agents because they:
  - (a) form soluble complexes with anionic species
  - (b) precipitate anionic species
  - (c) form soluble complexes with cationic species
  - (d) precipitate cationic species

Ans. (c)

- 14. What is false about  $H_2O_2$ ?
  - (a) Acts both as oxidising and reducing agent
  - (b) Two OH bonds lie in the same plane
  - (c) Pale blue liquid
  - (d) Can be oxidised by O<sub>3</sub>

Ans. (b)

[Hint: Two OH bonds lie in the different planes.]

# **OBJECTIVE QUESTIONS**

**Set I:** This set contains questions with one correct answer.

1.	Hydrogen has the tendency to gain one electron to acquire	14.	Heavy water is qualified as heavy because it is:	
	helium configuration, in this respect it resembles:		(a) a heavy liquid	
	(a) alkali metals $\Box$ (b) carbon $\Box$		(b) an oxide of a heavier isotope of oxygen $\Box$	
	(c) alkaline earth metals $\Box$ (d) halogens $\Box$		(c) an oxide of deuterium $\Box$	
2.	Pure hydrogen is obtained by carrying electrolysis of:		(d) denser than water $\Box$	
	(a) water containing $H_2SO_4$	15.	Both temporary and permanent hardness in water is removed	
	(b) water containing NaOH		by:	41
	(c) Ba(OH) <sub>2</sub> solution		(a) boiling $\Box$ (b) filtration . $\Box$	ز وگ
	(d) KOH solution		(c) distillation $\Box$ (d) decantation $\Box$	٤,
3.	In Bosch's process which gas is utilised for the production	16.	Both temporary and permanent hardness is removed on	
	of hydrogen?		boiling water with:	
	(a) Producer gas $\square$ (b) Water gas $\square$		(a) $Ca(OH)_2$ $\Box$ (b) $Na_2CO_3$ $\Box$	
	(c) Coal gas	İ	(c) $CaCO_3$ $\Box$ (d) $CaO$ $\Box$	
4.	In which property listed below hydrogen does not resemble	17.	Temporary hardness is caused due to the presence of:	
	alkali metals?		(a) $CaSO_4$ $\Box$ (b) $CaCl_2$ $\Box$	
	(a) Nature of oxide		(c) $CaCO_3$	
	(b) Reducing nature	18.	Permutit is:	
	(c) Tendency to form cation		(a) hydrated sodium aluminium silicate	
	(d) Presence of one electron in valence shell		(b) sodium hexametaphosphate	
5.	Adsorbed hydrogen by palladium is known as:		(c) sodium silicate	
	(a) atomic $\Box$ (b) nascent $\Box$		(d) sodium meta-aluminate	
	(c) occluded $\Box$ (d) heavy $\Box$	19.	Calgon is an industrial name given to:	
6.	The conversion of atomic hydrogen into ordinary hydrogen		(a) normal sodium phosphate $\Box$	
	18:		(b) sodium meta-aluminate	
	(a) exothermic change $\Box$ (b) endothermic change $\Box$		(c) sodium hexametaphosphate	
	(c) nuclear change $\Box$ (d) photochemical change $\Box$		(d) hydrated sodium aluminium silicate $\Box$	
7.	The gas used in the hydrogenation of oils in presence of	20.	Which of the following is not a water softener?	
	nickel as a catalyst is:		(a) Calgon $\square$ (b) Permutit $\square$	
	(a) methane $\Box$ (b) ethane $\Box$		(c) $Na_2CO_3$ $\square$ (d) $Na_2SO_4$ $\square$	
	(c) ozone $\Box$ (d) hydrogen $\Box$	21.		
8.	The isotopes of hydrogen known is/are:		excess of sulphuric acid and excess of sodium hydroxide, the	
	(a) 4		ratio of volumes of hydrogen evolved is:	
	(c) 2 $\square$ (d) 1 $\square$		(a) 1:1 $\Box$ (b) 1:2	
9.	Tritium contains neutron/neutrons.		(c) $2:1$	
	(a) 4	22.	The temporary hardness of water due to calcium bicarbonate	:
	(c) 2		can be removed by adding:	
10.	Tritium undergoes radioactive decay giving:		(a) $CaCO_3$ $\square$ (b) $CaCl_2$ $\square$	
	(a) $\alpha$ -particles $\square$ (b) $\beta$ -particles $\square$		(c) HC1 $\Box$ (d) Ca(OH) <sub>2</sub> $\Box$	
	(c) neutrons $\Box$ (d) $\gamma$ -rays $\Box$	23.	Which elements out of the following do not produce	:
11.	The decay product of tritium is:		hydrogen on treatment with caustic soda?	
	(a) ${}_{1}^{1}H$ · $\square$ (b) ${}_{1}^{2}H$ $\square$		(i) Zn (ii) Sn (iii) Cu (iv) Ca (v) Al	
	(c) ${}_{2}^{3}\text{He}$ $\square$ (d) ${}_{2}^{4}\text{He}$ $\square$		(a) (i) and (v) $\square$ (b) (iii) and (iv) $\square$	i
12.	Deuterium differs from hydrogen in:		(c) (ii) and (iv) $\square$ (d) (iv) and (v) $\square$	
	(a) chemical properties $\Box$ (b) physical properties $\Box$	24.	7	
	(c) both physical and chemical properties		lating through it a solution of:	
	(d) radioactive properties		(a) sodium chloride	
13.	In which of the following reactions does hydrogen act as		(c) magnesium chloride	
	an oxidising agent?	25.	1.3.	
	(a) $H_2 + F_2 \longrightarrow \square$ (b) $CH_2 = CH_2 + H_2 \longrightarrow \square$		(a) $PbO_2$ $\Box$ (b) $MnO_2$ $\Box$	
	(c) PbO + H <sub>2</sub> $\longrightarrow$ $\square$ (d) Ca + H <sub>2</sub> $\longrightarrow$ $\square$	1	(c) $Na_2O_2$ $\square$ (d) $TiO_2$ $\square$	į

26.	Hydrogen gas will not reduce:			(c) reducing agent	
	(a) heated cupric oxide			(d) none of the above	
	(c) heated stannic oxide (d) heated aluminium oxide		41.	Which hydride is called alanate?	
27.	Heavy water is:			(a) $CaH_2$	
	(a) $H_2O$ $\square$ (b) $D_2O$			(c) $NaBH_4$ $\square$ (d) $AlH_3$	
	(c) water at 4°C		42.	The volume of '10 vol.' of H <sub>2</sub> O <sub>2</sub> required to liberate 500 r	mL
	(d) water obtained by repeated distillation			O <sub>2</sub> at NTP is:	
28.	The sum number of neutrons and protons in one of	the		(a) $50 \text{ mL}$	
	isotopes of hydrogen is:			(c) $100 \mathrm{mL}$ $\square$ (d) $125 \mathrm{mL}$	
	(a) 3		43.	Hydrogen peroxide has a:	
	(c) 5			(a) linear structure	
29.	A commercial sample of H <sub>2</sub> O <sub>2</sub> is labelled as '15 volume'.	Its		(b) closed chain structure	
	percentage strength is nearly:			(c) closed book type structure	
	(a) 1%			(d) half open book type structure	
	(c) 10%		44.	Hydrogen peroxide does not:	
30.	The decomposition of H <sub>2</sub> O <sub>2</sub> can be slowed down by	the		(a) liberate iodine from KI	
	addition of small amount of phosphoric acid which acts	as:		(b) turn the titanium salt yellow	
	(a) stopper			(c) give silver peroxide with moist silver oxide	
	(c) inhibitor			(d) turn the mixture of aniline, KClO <sub>3</sub> and dil. H <sub>2</sub> SO <sub>4</sub> vio	let
31.	The colour of hydrogen is:				
	(a) yellow		45.	Hydrogen peroxide was for the first time prepared by:	
	(c) red $\Box$ (d) none			(a) Priestley	
32.	Hydrogen is evolved by the action of cold dilute HNO <sub>3</sub>	on:		(c) Gay-Lussac	
	(a) Fe		46.	Hydrogen peroxide is a:	
	(c) Mg			(a) liquid	
33.	Hard water is not fit for washing clothes because:			(c) solid	
	(a) it contains Na <sub>2</sub> SO <sub>4</sub> and KCl		47.	Hydrogen peroxide is:	
	(b) it gives precipitate with soap			(a) in the form of a dilute solution	
	(c) it contains impurities			(b) in pure form	
	(d) it is acidic in nature			(c) in impure form	
34.				(d) in gaseous state	
	(a) a reducing agent		48.	When 50% solution of H <sub>2</sub> SO <sub>4</sub> is electrolysed by passin	ga
	(c) a dehydrating agent  (d) a bleaching agent			current of high density at low temperature the main produ	
35.				of electrolysis are:	
,	(a) cold dilute H <sub>2</sub> SO <sub>4</sub> on hydrated BaO <sub>2</sub>			(a) oxygen and hydrogen	
	(b) dil. HCl on MnO <sub>2</sub>			(b) H <sub>2</sub> and peroxy disulphuric acid	
	(c) cold H <sub>2</sub> SO <sub>4</sub> on MnO <sub>2</sub>			(c) H <sub>2</sub> and SO <sub>2</sub>	
	(d) aqueous alkali on Na <sub>2</sub> O <sub>2</sub>			(d) O <sub>2</sub> and peroxy disulphuric acid	
36.	Which of the following hydride is most volatile?		49.	Which one of the following reactions shows oxidis	sing
	(a) Hydrolith			nature of H <sub>2</sub> O <sub>2</sub> ?	_
	(c) Sodium hydride			(a) $H_2O_2 + 2KI \longrightarrow 2KOH + I_2$	
37.	The bleaching properties of $H_2O_2$ are due to its:			(b) $Cl_2 + H_2O_2 \longrightarrow 2HCl + O_2$	
	(a) reducing properties $\square$ (b) oxidising properties			(c) $H_2O_2 + Ag_2O \longrightarrow 2Ag + H_2O + O_2$	
	(c) unstable nature			(d) NaClO + $H_2O_2 \longrightarrow NaCl + H_2O + O_2$	
38.	For the bleaching of hair, the substance used is:		50.	Ortho and Para hydrogen differ:	
	(a) $SO_2$ $\square$ (b) bleaching powder			(a) in the number of protons	
	(c) $H_2O_2$ $\square$ (d) $O_3$			(b) in the molecular mass	
39.	The reaction, $H_2S + H_2O_2 \rightarrow S + 2H_2O$ manifests:			(c) in the nature of spins of protons	
	(a) acidic nature of H <sub>2</sub> O <sub>2</sub>			(d) in the nature of spins of electrons	
	(b) alkaline nature of H <sub>2</sub> O <sub>2</sub>		51.	Decolourisation of acidified potassium permanganate occ	
	(c) oxidising action of H <sub>2</sub> O <sub>2</sub>			when $H_2O_2$ is added to it. This is due to:	
	(d) reducing nature of H <sub>2</sub> O <sub>2</sub>			(a) oxidation of KMnO <sub>4</sub>	
40.	$H_2O_2$ is:	- <del>-</del>		(b) reduction of KMnO <sub>4</sub>	
	(a) an oxidising agent			(c) both oxidation and reduction of KMnO <sub>4</sub>	
	(b) both oxidising and reducing agent			(d) none of the above	
	· · · · · · · · · · · · · · · · · · ·		1	4. A	_

52.	Which of the following metals adsorbs hydrogen?		66.	Hydrogen directly combines with:	
	(a) Zn	ן נ		(a) Ca	
	(c) Al	]		(c) Al	
53.	The permanent hardness of water can be removed by boiling	g	67.	The metal which displaces hydrogen from a boiling caus	stic
	the water with:			soda solution is:	
	(a) NaOH $\Box$ (b) Na <sub>2</sub> CO <sub>3</sub> $\Box$	]		(a) Ag	
	(c) $Na_3PO_4$	ן נ		(c) Mg	
54.	Hydrogen reacts with the following in the dark:			Hydrogen peroxide is used as:	
	(a) $Br_2$ $\square$ (b) $F_2$ $\square$			(a) oxidising agent	
	(c) $I_2$ $\square$ (d) $Cl_2$	]		(b) reducing agent	
55.	H <sub>2</sub> O <sub>2</sub> reduces K <sub>3</sub> Fe(CN) <sub>6</sub> in:	_		(c) both as oxidising and reducing agent	
	(a) neutral solution	1		(d) drying agent	
E.C	(c) alkaline medium	- 1		The melting points of most of the solid substances incre	
36.	In which of the following reactions does water act as a	n		with an increase of pressure acting on them. However,	
	oxidising agent?	<b>,</b>		melts at a temperature lower than its usual melting point when the process is in process. This is because	nen
	(a) $3F_2 + 3H_2O \longrightarrow 6HF + O_3$ (b) $CaC_2 + 2H_2O \longrightarrow Ca(OH)_2 + C_2H_2$			the pressure is increased. This is because: (a) ice is less dense than water	
	(c) $C + H_2O \longrightarrow CO + H_2$ [2] (d) $AIN + 3H_2O \longrightarrow AI(OH)_3 + NH_3$ [5]	- 1		<ul><li>(b) it generates heat</li><li>(c) chemical bonds break under pressure</li></ul>	
57	The species that do not contain peroxide ions are:	-		(d) none of the above	
٥,,	(a) $PbO_2$ $\Box$ (b) $H_2O_2$ $\Box$	٦		A mixture of hydrazine and $H_2O_2$ is:	
	(c) $SrO_2$ $\Box$ (d) $BaO_2$	1		(a) antiseptic	
58.	The 'volume strength' of $1.5 N H_2O_2$ solution is:	-		(c) germicide	
	(a) 4.8	- l		Decomposition of H <sub>2</sub> O <sub>2</sub> is accelerated by:	
	(c) 3.0	- 1		(a) traces of acids	
59.	When zeolite, which is hydrated sodium aluminium silicate	e,		(c) finely divided metals □ (d) alcohol	
	is treated with hard water the sodium ions are exchanged with	- 1	72.	The shape of water molecule is same as that of:	
	(a) $H^+$ ions $\Box$ (b) $Ca^{++}$ ions $\Box$			(a) $C_2H_2$	
	(c) $SO_4^-$ ions $\Box$ (d) $OH^-$ ions $\Box$	ן		(c) $NH_3$ $\Box$ (d) $Cl_2O$	
60.	Which of the following statements is incorrect?[BHU 2008	3]	73.	20 mL of a sample of H <sub>2</sub> O <sub>2</sub> gives 400 mL of oxyg	gen
	(a) H <sub>2</sub> O <sub>2</sub> can act as an oxidising agent	J		measured at NTP. The sample should be labelled as:	
	· · · · · · · · · · · · · · · · · · ·	<b>]</b>		(a) 5 vol. $H_2O_2$	
		]		(c) anhydrous $H_2O_2$ $\square$ (d) 20 vol. $H_2O_2$	
	(-)Z-Z FF	]	74.	An orange coloured solution acidified with H <sub>2</sub> SO <sub>4</sub> and trea	
61.	The hybrid state and oxidation state of two oxygen atoms i	n,		with a substance 'X' gives a blue coloured solution of Cr	:O <sub>5</sub> .
	$H_2O_2$ are respectively:	_ 1		The substance 'X' is:	_
		⊒		(a) $H_2O$ $\Box$ (b) dil. $HCl$	
62	(c) $sp^3$ , $-1$	]	. 75	(c) H <sub>2</sub> O <sub>2</sub>	
62.	Given colourless liquid will be determined whether it is water or not?	21	13.	Consider the two reactions:	
		<b>-</b>		$(x) H2O2 + H2S \longrightarrow S + 2H2O$	
				$(y)  H_2O_2 + O_3 \longrightarrow 2O_2 + H_2O$	
				H <sub>2</sub> O <sub>2</sub> acts as:	
		<u> </u>		(a) oxidising agent in both (x) and (y)	
63.	Heavy water is used in atomic reactor as:		٠.	(b) oxidising in (x) and reducing in (y)	
		<b>-</b>		(c) reducing in (x) and oxidising in (y)	
	(b) moderator	<b>]</b>		(d) reducing in both (x) and (y)	
	(c) both coolant and moderator	<b>-</b>	76.	Hydrogen can be placed in VIIA (or 17th group) of period	odic
	(d) neither coolant nor moderator	<b>]</b>		table because:	_
64.	Heavy water freezes at:			(a) hydrogen forms hydrides like NaH	
				(b) hydrogen has isotopes D and T	
				<ul><li>(c) it is light</li><li>(d) hydrogen combines with halogens</li></ul>	
65.	Hydrogen does not combine with:	_,	77	H <sub>2</sub> O <sub>2</sub> $\longrightarrow$ 2H <sup>+</sup> + O <sub>2</sub> + 2e <sup>-</sup> , $E^{\circ}$ = -0.68 V	ب
			, , , .	The above equation represents which of the follow	vino
	(c) Sb		ļ	behaviour of H <sub>2</sub> O <sub>2</sub> ?	·s

	(a) Reducing	l (b) Oxidising		84.	The H—O—H angle in	water	molecule is abou	ıt:
	(c) Acidic	l (d) Catalytic			*		[A	F.M.C. 2001]
78.	Which of the following is a	true structure of H <sub>2</sub> O <sub>2</sub> ?			(a) 90°		(b) 180°	
	180°	H 297°			(c) 102°		(d) 105°	
	(a) H <b>Y</b> O <b>Y</b> O—H □	] (p) \O_\(\pi\)		85.	When two ice cubes ar	e press	sed over each other	er, they unite
	ң ң	1 (d) H O=O			to form one cube. Whi	ch of t	he following force	es is respon-
	94° 94°	Н,			sible to hold them toge	ther?	[A	.F.M.C. 2001]

## **Objective Questions for IIT ASPIRANTS**

1. Hydrogen behaves as an oxidising agent in its reaction w	gen behaves a	as an	oxidising	agent m	IUS	reaction	WIU.
---	---------------	-------	-----------	---------	-----	----------	------

- (a) chlorine
- (b) potassium
- (c) nitrogen
- □ (d) sulphur

П [Hint: An oxidising agent is a species which accepts an electron or electrons. Hydrogen accepts an electron from potassium when it forms KH

$$H_2 + 2K \longrightarrow 2KH (K^+H^-)]$$

- 2. Hydrogen cannot be obtained by:
  - (a)  $Zn + dil. H_2SO_4$
- $\Box$  (b) Zn + dil. HNO<sub>3</sub>
- (c)  $Mg + H_2O$
- $\Box$  (d) Mg + dil. H<sub>2</sub>SO<sub>4</sub>

[Hint: Zn reacts to form hydrogen with dilute HNO3. Before the hydrogen is released, it reduce HNO3 into an oxide of

- 3. Hydrogen peroxide ionises as:  $H_2O_2 \rightleftharpoons H^+ + HO_2^-$ . If pH of H<sub>2</sub>O<sub>2</sub> is 5.91 at 25°C, the ionic product of H<sub>2</sub>O<sub>2</sub> is:
  - (a)  $1.51 \times 10^{-12}$
- $\Box$  (b) 1.15 × 10<sup>-12</sup>
- (c)  $1 \times 10^{-14}$
- $\Box$  (d)  $1.1 \times 10^{-12}$

[Hint: [H<sup>+</sup>] at  $25^{\circ}$ C =  $10^{-5.91}$  =  $1.23 \times 10^{-6}$  M;  $[HO_2^-] = 1.23 \times 10^{-6} M$ 

 $K = [H^+] [HO_7^-] = [1.23 \times 10^{-6}]^2 = 1.51 \times 10^{-12}]$ 

- 4. Which of the following hydrides conducts electricity?
  - (a) SiH<sub>4</sub>
- $\Box$  (b)  $B_2H_6$
- (c) CH<sub>4</sub>
- □ (d) KH

[Hint: KH is a crystalline solid, in molten state it conducts electricity as it possesses K<sup>+</sup> and H<sup>-</sup> ions.]

- 5. The correct increasing order of the acidity of CO<sub>2</sub>, H<sub>2</sub>O and H<sub>2</sub>O<sub>2</sub> is:
- 6. Hydrogen combines with other elements by:
  - (a) losing an electron
  - (b) gaining an electron
  - (c) sharing an electron
  - (d) (a), (b), (c) all are correct
- 7. Metallic hydride is formed by:
  - (a) iron
- (b) manganese
- (c) palladium
- (d) molybdenum

## **Assertion-Reason Type Questions**

The following questions consist of two statements each, Assertion (A) and Reason (R). You are required to choose any one of the following responses for each question.

- (a) If both (A) and (R) are true and the (R) is a correct explanation of the (A).
- (b) If both (A) and (R) are true but (R) is not the correct explanation of (A).
- (c) If (A) is true but (R) is false.
- (d) If (A) is false but (R) is true.
- (e) If both (A) and (R) are false.
- 1. (A) Alkali metals form ionic hydrides.
  - (R) Alkali metals lose their valency electron which is accepted by hydrogen to form a negative ion.
- 2. (A) When blood is added to a solution of H<sub>2</sub>O<sub>2</sub>, the solution bubbles furiously.
  - (R) Catalase (an enzyme) present in blood decomposes H<sub>2</sub>O<sub>2</sub> and produces bubbles of O<sub>2</sub>.
- 3. (A) Old lead paintings regain their original colour by washing with hydrogen peroxide solution.
  - (R) Hydrogen peroxide dissolves the blackened layer by virtue of its acidic nature.

- **4.** (A) The process of adsorption of hydrogen on palladium is known as occlusion.
  - (R) The adsorbed hydrogen is more active than ordinary hydrogen.
- 5. (A) Hydrogen is prepared in the laboratory by the action of conc. H<sub>2</sub>SO<sub>4</sub> on zinc metal.
  - (R) Pure hydrogen can be obtained by the action of water on sodium hydride.
- 6. (A) Hard water is used in a nuclear reactor.
  - (R) Dilute solution of H<sub>2</sub>O<sub>2</sub> under the name of **perhydrol** is used in medicines as antiseptic for washing wounds, teeth, ears, etc.
- 7. (A) Normal hydrogen consists of a mixture of two forms: ortho (75%) and para (25%).
  - (R) Pure ortho form can be obtained at low temperature but pure para form cannot be obtained.
- 8. (A)  $H_2O_2$  is a linear molecule.
  - (R) Each oxygen is sp-hybridized.
- 9. (A) NaCl is less soluble in heavy water than in ordinary water.
  - (R) Dielectric constant of ordinary water is more than that of heavy water. [E.A.M.C.E.T. (Engg.) 2007]

## THOUGHT TYPE QUESTIONS

## THOUGHT 1

Hydrogen is thought to account for approximately 75% of the mass of the universe. Our sun and other stars, for instance, are composed mainly of hydrogen, which serves as their nuclear fuel. On earth, though hydrogen is rarely found in its uncombined state because earth's gravity is too weak to hold such light molecules. Nearly all the H<sub>2</sub> originally present in the earth's atmosphere has been lost to space. In the earth's crust and oceans, hydrogen is found in water, petroleum, proteins, carbohydrates, fats and literally millions of other compounds and is ninth most abundant element on a mass basis.

There are three isotopes of hydrogen: protium or ordinary hydrogen ( ${}^1_1H$ ); deuterium or heavy hydrogen ( ${}^2_1H$  or D) and tritium ( ${}^3_1H$  or T). The chemical properties of the three isotopes are similar because they have same electron configuration. The physical properties of three isotopes are different due to difference in their masses, *i.e.*, isotope effects.

The reaction of hydrogen and oxygen is highly exothermic, and gas mixtures that contain as little as 4% by volume hydrogen in oxygen (or in air) are highly flammable and potentially explosive.

$$2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$$
  $\Delta H^\circ = -484 \text{ kJ}$ 

Hydrogen is an enormously attractive fuel because it is environmentally clean. 'Hydrogen economy' is a new field in which it is thought that our energy needs can be meet by gaseous, liquid and solid hydrogen. Since hydrogen is not a naturally occurring substance like coal, oil or natural gas, energy must be expended to produce hydrogen before it can be used. Current research therefore focuses on finding cheaper methods for extracting hydrogen.

- 1. Which fuel does produce least environmental pollution?
  - (a) Gasoline
- (b) Hydrogen
- (c) Wood
- (d) Coal
- 2. If an isotope of hydrogen has two neutrons in its atom, its atomic number and atomic mass number will respectively be:

(a) 2 and 1

(b) 3 and 1

(c) 1 and 1

- (d) 1 and 3
- 3. Which of the following gas is lightest?

  - (a) Oxygen
- (b) Nitrogen
- (c) Hydrogen
- (d) Helium
- 4. Which isotope of hydrogen is radioactive in nature?

  - (a) Protium only
- (b) Deuterium only
- (c) Deuterium and tritium
- (d) Tritium only
- 5. Abundance of H<sub>2</sub> in the earth's atmosphere is very small. This is because:
  - (a) the earth's gravity is weak to hold light molecules
  - (b) the hydrogen is inflammable
  - (c) the hydrogen readily combined with oxygen of atmosphere
  - (d) the hydrogen is diatomic in nature
- 6. Liquid H<sub>2</sub> has been used as a rocket fuel because of:
  - (a) high thrust
  - (b) its reaction with oxygen is highly exothermic
  - (c) small space it occupies
  - (d) all these are correct

## THOUGHT 2

$$\begin{bmatrix} \text{Red Hot Coke} \\ + \\ \text{Steam} \end{bmatrix} \xrightarrow[\text{Steam}]{1000^{\circ}\text{C}} \xrightarrow[\text{Steam}]{'X'} \xrightarrow[\text{Catalyst}]{500^{\circ}\text{C}} \xrightarrow[\text{Catalyst}]{'A'} + \text{H}_{2}$$

- 1. The above sequence refers to:
  - (a) Lane's process
- (b) Bosch's process
- (c) Haber's process
- (d) Ostwald's process

- 'X' is:
  - (a) water gas
- (b) producer gas
- (c) coal gas
- (d) oil gas

- 'A' is:
  - (a) carbon monoxide
- (b) oxygen
- (c) carbon dioxide
- (d) water
- 4. The catalyst 'Y' is:
  - (a)  $V_2O_5$
- (b) Ni

(c) Fe

- (d)  $Cr_2O_3 + Fe_2O_3$
- 'A' is removed by passing the gaseous mixture:
- (a) through water under high pressure of 25 atmospheres
  - (b) through acidic solution
  - (c) through alkaline solution
  - (d) through an organic solvent

#### THOUGHT 3

Hydrogen peroxide is a powerful oxidising agent. It is an electron acceptor in acidic and alkaline mediums.

$$H_2O_2 + 2H^+ + 2e \longrightarrow 2H_2O$$

(in acidic medium)

$$H_2O_2 + 2e \longrightarrow 2OH^-$$

(in alkaline medium)

It can also act as a reducing agent towards powerful oxidising agents:

$$H_2O_2 \longrightarrow 2H^+ + O_2 + 2e$$

In alkaline medium, however, its reducing nature is more effective.

$$H_2O_2 + 2OH^- \longrightarrow 2H_2O + O_2 + 2e$$

- 1. In which of the following reactions, H<sub>2</sub>O<sub>2</sub> acts as a reducing
  - (a)  $PbO_2 + H_2O_2 \longrightarrow PbO + H_2O + O_2$
  - (b)  $Na_2SO_3 + H_2O_2 \longrightarrow Na_2SO_4 + H_2O$
  - (c)  $2KI + H_2O_2 \longrightarrow 2KOH + I_2$
  - (d)  $KNO_2 + H_2O_2 \longrightarrow KNO_3 + H_2O$
- 2. In which of the following reactions, H<sub>2</sub>O<sub>2</sub> acts as an oxidising agent?
  - (a)  $IO_4^- + H_2O_2 \longrightarrow IO_3^- + H_2O + O_2$
  - (b)  $2I^{-} + H_2O_2 + 2H^{+} \longrightarrow I_2 + 2H_2O$
  - (c)  $Ag_2O + H_2O_2 \longrightarrow 2Ag + H_2O + O_2$
  - (d)  $2MnO_4^- + 6H^+ + 5H_2O_2 \longrightarrow 2Mn^{2+} + 8H_2O + 5O_2$
- 3. In the reaction,  $H_2O_2 + O_3 \longrightarrow H_2O + 2O_2$ ,  $H_2O_2$  acts as :
  - (a) an acid
  - (b) an oxidising agent
  - (c) a reducing agent
  - (d) both as a reducing agent and an oxidising agent

[Hint: O<sub>3</sub> acts as an oxidising agent as it gives oxygen which oxidised H2O2.

$$H_2O_2 + O \longrightarrow H_2O + O_2$$

- 4. The bleaching properties of H<sub>2</sub>O<sub>2</sub> are due to its:
  - (a) unstable nature
- (b) acidic nature
- (c) reducing nature
- (d) oxidising nature
- 5. Decolourisation of acidified KMnO<sub>4</sub> occurs when H<sub>2</sub>O<sub>2</sub> is added to it. This is due to:
  - (a) oxidation of KMnO<sub>4</sub>
  - (b) reduction of KMnO<sub>4</sub>
  - (c) both oxidation and reduction of KMnO4
  - (d) none of the above

## THOUGHT 4

On large scale, H<sub>2</sub>O<sub>2</sub> is prepared by hydrolysis of peroxydisulphuric acid obtained by electrolysis of 50% H<sub>2</sub>SO<sub>4</sub>. The strength of H<sub>2</sub>O<sub>2</sub> is expressed in number of ways namely normality, molarity, percentage strength and volume strength. Volume strength refers to the volume of O<sub>2</sub> obtained at NTP by decomposition of ImL of H<sub>2</sub>O<sub>2</sub> solution.

- 1. The volume of 20 volume H<sub>2</sub>O<sub>2</sub> solution that decolourises 200 mL of 2 N KMnO<sub>4</sub> solution in acidic medium is:
  - (a) 112mL
- (b) 336 mL
- (c) 200 mL
- (d) 224 mL

[Hint: Normality of 20 volume  $H_2O_2 = \frac{20}{5.6} N$ 

$$\therefore \frac{20}{5.6} \times V = 2 \times 200 \quad \text{or} \quad V = 112 \text{ mL} \quad ]$$

- 2. Hydrolysis of one mole of peroxydisulphuric acid gives:
  - (a) two moles of H<sub>2</sub>SO<sub>4</sub>
  - (b) two moles of Caro's acid
  - (c) one mole of H<sub>2</sub>SO<sub>4</sub> and one mole of H<sub>2</sub>SO<sub>5</sub>
  - (d) one mole of H<sub>2</sub>SO<sub>4</sub>, one mole of H<sub>2</sub>SO<sub>5</sub> and one mole of  $H_2O_2$

- 3. The volume strength of 1.5  $N H_2O_2$  solution is:
  - (a) 4.8

(b) 5.2

(c) 8.8

(d) 8.4

[Hint: Volume strength =  $5.6 \times \text{normality}$ ]

- 4. Commercial 11.2 volume H<sub>2</sub>O<sub>2</sub> solution has molarity of:
  - (a) 1.0

(c) 11.2

- (d) 1.12
- [Hint: Molarity =  $\frac{\text{Volume strength}}{110}$ ]

- What is the volume of O<sub>2</sub> liberated at NTP by complete decomposition of 100 mL of 2 M solution of H<sub>2</sub>O<sub>2</sub>?
  - (a) 22.4 L
- (b) 2.24 L
- (c) 0.224 L
- (d) 224L

[Hint: Volume strength =  $11.2 \times Molarity = 22.4$ 

$$100 \text{ mL} = 0.1 \text{ L}, i.e., 22.4 \times 0.1$$

= 
$$2.24 L O_2$$
 released ]

## BRAIN STORMING PROBLEMS

5. (b)

- 1. What is the oxidation state of hydrogen in N<sub>3</sub>H and NH<sub>3</sub>? Indicate the nature of these compounds.
  - [Hint:N3H

Thought 4

- (Hydrogen in +1 state; acidic)
- NH<sub>3</sub>

1. (a)

- (Hydrogen in +1 state; basic)]
- 2. Write two examples of bridging hydrogens.

2. (c)

$$\begin{bmatrix} H \\ Ans. \\ H \end{bmatrix} B \begin{pmatrix} H \\ H \end{pmatrix} CO & CO \\ CO \\ H & CO \\ CO \\ CO \end{bmatrix} \leftarrow CO$$

3. Write down hydrogen bonded coordinated water in hydrates.

$$\begin{bmatrix} H & H & M & H \\ H & O - M; & O - M; \\ H & H & H \end{bmatrix} O \begin{pmatrix} M \\ M \end{pmatrix}$$

**4.** What is mass in grams of available  $O_2$  per litre from a solution of H<sub>2</sub>O<sub>2</sub>, 10 mL of which when titrated with N/20 KMnO<sub>4</sub> solution, required 25 mL for the reaction?

$$2KMnO_4 + 5H_2O_2 + 4H_2SO_4 \longrightarrow$$

$$5O_2 + 8H_2O + 2KHSO_4 + 2MnSO_4$$

[**Hint**: 
$$N_1V_1$$
 (KMnO<sub>4</sub>) =  $N_2V_2$  (H<sub>2</sub>O<sub>2</sub>)

$$\frac{1}{20} \times 25 = N_2 \times 10$$

$$N_2 = \frac{25}{200} = \frac{1}{8}$$

$$W = N \times \text{Eq. mass} = \frac{1}{8} \times 16 = 2 \text{ g}$$

5. Excess of KI and dil. H<sub>2</sub>SO<sub>4</sub> were mixed in 50 mL H<sub>2</sub>O<sub>2</sub>. The liberated I<sub>2</sub> requires 20 mL of 0.1 N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. Find out the strength of H<sub>2</sub>O<sub>2</sub> in g/litre.

[Hint:

$$N_1V_1$$
 (H<sub>2</sub>O<sub>2</sub>) =  $N_2V_2$  (hypo)

$$N_1 \times 50 = 0.1 \times 20$$

$$N_1 = \frac{1}{25}$$

 $N_1 = \frac{1}{25}$ g/litre strength =  $N \times \text{Eq. mass}$ 

$$=\frac{1}{25} \times 17 = 0.68$$
 g/litre]

6. What is Fenton's reagent?

[Hint: Fe<sup>2+</sup>/H<sub>2</sub>O<sub>2</sub> used as oxidising agent or dehydrogenating agent for organic compound.]

7. In some tooth pastes hydrogen peroxide is used. What is role of  $H_2O_2$  in it?

[Ans. Hydrogen peroxide is used as antiseptic.]

8. Hydrogen peroxide acts as oxidising agent in acidic as well as basic mediums. Substantiate this fact by electrode potential data.

[Ans. 
$$H_2O_2 + 2H^+ + 2e^- = 2H_2O$$
;  $E^\circ = 1.77 \text{ V}$   
 $O_2 + 2H^+ + 2e^- = H_2O_2$ ;  $E^\circ = 0.68 \text{ V}$   
 $HO_2^- + H_2O + 2e^- = 3OH^-$ ;  $E^\circ = 0.87 \text{ V}$ ]

9. There are three samples of  $H_2O_2$  labelled as 10 vol; 15 vol; 20 vol. Half litre of each sample are mixed and then diluted with equal volume of water. Calculate volume strength of resultant solution.

[Hirat: We know,  $V = 5.6 \times N$ 

$$N_1 = \frac{10}{56}$$
;  $N_2 = \frac{15}{56}$ ,  $N_3 = \frac{20}{56}$ 

$$N_1V_1 + N_2V_2 + N_3V_3 = N_RV_R$$

$$\frac{10}{5.6} \times \frac{1}{2} + \frac{15}{5.6} \times \frac{1}{2} + \frac{20}{5.6} \times \frac{1}{2} = N_R \times 3$$

$$N_{\rm p} = 1.339$$

Volume strength =  $N_R \times 5.6 = 1.339 \times 5.6 = 7.5$ ]

- 10. Answer the following questions:
  - (a) Indicate whether ortho or para hydrogen has zero
  - (b) Indicate whether ortho or para hydrogen can be obtained in pure form.

[Ans. (a) Para hydrogen

- (b) At 0K 100% para hydrogen can be obtained.]
- 11. Predict whether H<sub>2</sub>O<sub>2</sub> acts as oxidising or reducing agent in following reactions:

(i) 
$$IO_4^- + H_2O_2 \longrightarrow IO_3^- + O_2 + H_2O$$

(ii) 
$$PbS + 4H_2O_2 \longrightarrow PbSO_4 + 4H_2O$$

(iii) 
$$Ag_2O + H_2O_2 \longrightarrow 2Ag + H_2O + O_2$$

(iv) 
$$Au_2O + H_2O_2 \longrightarrow 2Au + H_2O + O_2$$

(v) 
$$2I^- + H_2O_2 + 2H^+ \longrightarrow I_2 + 2H_2O$$

[Ans. (i), (iii), (iv) Reducing agent; (ii), (v) Oxidising agent]

12. A 5 mL of H<sub>2</sub>O<sub>2</sub> solution liberates 0.508 g I<sub>2</sub> from an acidified KI solution. Calculate strength of H<sub>2</sub>O<sub>2</sub> solution in terms of volume strength at STP.

[Ans. 4.48]

[Hint: 
$$2KI + H_2O_2 \longrightarrow 2KOH + I_2$$
1 mole 1 mo

∴ 254 g I<sub>2</sub> is produced by 1 mole H<sub>2</sub>O<sub>2</sub>

∴ 0.508 g I<sub>2</sub> is produced by  $\frac{1}{254} \times 0.508$  mole H<sub>2</sub>O<sub>2</sub> = 2 × 10<sup>-3</sup>

$$\begin{split} \text{Molarity of } H_2O_2 &= \frac{\text{number of moles}}{\text{volume in mL}} \times 1000 \\ &= \frac{2 \times 10^{-3}}{5} \times 1000 = 0.4 \\ \text{Volume strength} &= \text{Molarity} \times 11.2 = 0.4 \times 11.2 = 4.48] \end{split}$$

13. How many types of heavy water are possible? Write down formulae of all possible heavy water molecules.

[Ans. There are six possible heavy water molecules

14. What is perhydrol? Give its composition and use.

[Ans. 30% H<sub>2</sub>O<sub>2</sub> is called perhydrol which is used as an antiseptic and germicide for washing wounds, teeth and ears.]

15. Give an example in which H<sub>2</sub>O acts as reducing agent.

[Ans. 
$$2F_2 + 2H_2O \longrightarrow O_2 + 4HF$$
  
In above reaction,  $H_2O$  acts as reducing agent.]

16. How the active hydrogen can be obtained?

[Ans. Active hydrogen can be obtained by subjecting molecular hydrogen to silent electric discharge at ordinary temperature and 0.5 mm pressure. This hydrogen has great chemical activity. The half-life period of active hydrogen is similar to that of atomic hydrogen (0.3 sec).]

- 17. Answer the following questions:
  - (i) Which of the following cannot be oxidised by H<sub>2</sub>O<sub>2</sub>?

- (ii) Hydrogen peroxide is used to wash old oil paintings. Write down the reaction involved in this process.
- (iii) H<sub>2</sub>O<sub>2</sub> on reaction with ethene gives a commercially important compound. Write down name of this compound
- (iv) Arrange CO<sub>2</sub>, H<sub>2</sub>O and H<sub>2</sub>O<sub>2</sub> in decreasing order of acidic
- (v) Give the pH of D<sub>2</sub>O and H<sub>2</sub>O at 298 K.

[Ans. (i) 
$$O_3$$
 (ii) PbS +  $4H_2O_2 \rightarrow PbSO_4 + 4H_2O$ 

$$CH_2OH$$
(iii) | ; It is used as antifreeze in the radiator of car.

CH<sub>2</sub>OH (Ethylene glycol)

- (iv)  $CO_2 > H_2O_2 > H_2O$
- (v) 7.35 and 7.0]

(v) 7.35 and 7.0 ]

18. [A] + Na[Cr(OH)<sub>4</sub>] 
$$\xrightarrow{\text{H}_2\text{O}_2}$$
 [B]  $\xrightarrow{\text{H}_2\text{SO}_4}$  [C]

Yellow Orange coloured compound

What are [A], [B] and [C]? Give the reactions involved.

[Hint: 
$$2\text{NaCr}(OH)_4 + 2\text{Na}OH + 3\text{H}_2\text{O}_2 \longrightarrow 2\text{Na}_2\text{Cr}O_4 + 8\text{H}_2\text{O}$$

[A]

[B]

 $2\text{Na}_2\text{Cr}O_4 + \text{H}_2\text{SO}_4 \longrightarrow \text{Na}_2\text{Cr}_2\text{O}_7 + \text{Na}_2\text{SO}_4 + \text{H}_2\text{O}]}$ 

[B]

[C]

19. Two liquids (A) and (B) are made of same elements and are diamagnetic. Liquid (A) on treatment with KI and starch gives blue coloured solution, however, liquid (B) is neutral to litmus and does not give any response to starch iodide paper.

[Ans. 
$$(A) \rightarrow H_2O_2$$
;  $(B) \rightarrow H_2O$ ]

20. Volume strength of  $H_2O_2$  is 22.4. What volume of it is required to oxidise 3.4 g H<sub>2</sub>S gas? [Ans. 100 mL]

21. 25 mL H<sub>2</sub>O<sub>2</sub> on treatment with excess of acidified KI solution liberates iodine. Liberated iodine requires 20 mL of 0.3 N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> solution. Calculate volume strength of H<sub>2</sub>O<sub>2</sub> solution.

[Ans. 1.334]

[Hint: 
$$N_1V_1(H_2O_2) = N_2V_2(Na_2S_2O_3)$$
  
 $N_1 \times 25 = 0.3 \times 20$   
 $N_1 = 0.24$   
Volume strength of  $H_2O_2 = Normality \times 5.6$   
 $= 0.24 \times 5.6 = 1.344$ ]

22. Naturally hard water is usually preferred in drinking and soft water in working why?

[Ans. Soft water is usually acidic and contains Na<sup>+</sup> ions in place of di- and trivalent metal ions. An increased in take of Na<sup>+</sup> is known to be related to heart disease and moreover the acidic soft water is more likely to attack metallic pipes, resulting in the solution of dangerous ions such as Pb2+. One way to avoid sodium ions in drinking water and to use less soap when washing would be to drink naturally hard water and work in soft water.]

## INTEGER ANGWER INDÉGRESSIONS

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

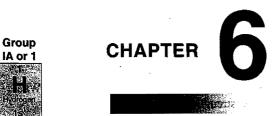

- 1. What is the sum of protons, electrons and neutrons in the heaviest isotope of hydrogen?
- 2. How much volume of 10 volume  $H_2O_2$  is required to liberate 50 cm<sup>3</sup> of oxygen at STP?
- 3. One mole of calcium phosphide on reaction with excess of water gives . . . . mole/s of phosphine.
- **4.** A commercial sample of H<sub>2</sub>O<sub>2</sub> is labelled as '10 volume'. What is its percentage strength?
- 5. What is the degree of hardness of a sample of water containing 6 mg of MgSO<sub>4</sub> (molecular mass 120) per kg of water?
- **6.** What is the molarity of a commercial sample of 33.6 volume hydrogen peroxide solution?

## Auswers

- 1. (4) In tritium atom one proton, one electron and two neutrons are present.
- 2. (5) 10 mL of  $O_2$  is obtained at STP from  $H_2O_2 = 1$  mL
- 3. (2)  $Ca_3P_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2PH_3$
- 4. (3)  $2H_2O_2 \longrightarrow 2H_2O + O_2$   $_{68 \text{ g}}$   $10 \text{ mL of oxygen is obtained from } = \frac{68}{22400} \times 10 = 0.03 \text{ g } H_2O_2$   $1 \text{ mL of } H_2O_2 \text{ solution contains } = 0.03 \text{ g } H_2O_2$

100 mL of  $H_2O_2$  solution contains = 3.0 g  $H_2O_2$ 

- 5. (5) 6 mg of MgSO<sub>4</sub> present in  $10^3$  g of water.  $10^6$  g water will contain = 6000 mg of MgSO<sub>4</sub> = 6g of MgSO<sub>4</sub> 120 g of MgSO<sub>4</sub> = 100 g of CaCO<sub>3</sub> So, 6 g of MgSO<sub>4</sub> =  $\frac{100}{120} \times 6 = 5$  g of CaCO<sub>3</sub> *i.e.*, Hardness = 5 ppm
- **6.** (3) Molarity =  $\frac{\text{Volume strength}}{11.2} = \frac{33.6}{11.2} = 3$

## 6.1 POSITION OF ALKALI METALS IN PERIODIC TAB 🗵

The members of Group IA or 1, except hydrogen are called the alkali metals, because they react with water to form alkaline solutions. All the group 1A elements are soft silvery-grey metals. Their valence electron configurations are ns<sup>1</sup>, where n is the period number, and their physical and chemical properties are dominated by the ease with which the single valence electron can be removed. The group IA of the periodic table consists of six elements—lithium, sodium, potassium, rubidium, caesium and francium besides hydrogen. These elements are collectively called as alkali metals and group IA is known as alkali group as the hydroxides of these metals are soluble in water and these solutions are highly alkaline in nature. The word alkali has been derived from Arabic word 'Alquili' meaning the ashes of plants from which compounds of sodium and potassium were first isolated. They are soft enough to cut with a knife (Fig. 6.4). The alkali metals are the most reactive of all metals, reacting readily with water and air. The alkali metals, being reactive in nature, are never found free in nature but always found in combined state. The alkali metals are so reactive that, they must be stored under oil. This prevents the reaction of alkali metals with oxygen and water vapour in the air.

Of all the alkali metals, only sodium and potassium are found in abundance in nature, *i.e.*, they are seventh and eighth most abundant elements by weight in earth's crust. Their compounds are very common and have been known and used from very early times. The last member, francium, occurs only in traces as a radioactive decay product because its half life period is very small, *i.e.*, 21 minutes. Thus, not much is known about this element. The following table shows the percentage and relative abundance of alkali metals in earth's crust by weight.

Element	Percentage	Relative abundance
Li	0.0018	35
Na	2.27	7
K	1.84	8
Rb	0.0078	. 23
Cs	0.00026	46

Each alkali metal occupies a place just after a member of Zero group. Except first period, rest of the six periods of the periodic table start with a member of

alkali group. Next to the elements of Zero group, alkali metals form the most homogeneous of all the groups of the periodic table. The members of this group show a marked resemblance in their properties and possess the same electronic configuration. There is gradual gradation in the properties with the increase of atomic number. This justifies their inclusion in the same group of the periodic table. The main properties of alkali metals are discussed below for this justification.

#### 3 1. Electronic Configuration

The arrangement or the distribution of electrons on various subshells in the atoms of alkali metals is given below:

Element	At. No.		Electronic configuration	Configuration of the valency shell
Li	3	2, 1	$1s^2$ , $2s^1$	$2s^1$
Na	11	2, 8, 1	$1s^2$ , $2s^2$ $2p^6$ , $3s^1$	$3s^1$
K	19	2, 8, 8, 1	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ , $4s^1$	$4s^1$
Rb	37	2, 8, 18, 8, 1	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ , $5s^1$	$5s^1$
Cs	55	2, 8, 18, 18, 8, 1	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ , $5s^2$ $5p^6$ , $6s^1$	6s <sup>1</sup>
Fr	87	2, 8, 18, 32, 18, 8, 1	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}4f^{14}$ , $5s^2$ $5p^6$ $5d^{-1}$ , $6s^2$ $6p^6$ , $7s^1$	7s¹

The outermost shells of these elements have one electron and the penultimate (next to outermost) shells contain 8 electrons except in the first member, lithium, which contains 2 electrons, which is the atomic number of helium. Since, the last electron enters *ns*-orbital, these are called *s*-block elements.

Lithium shows somewhat abnormal properties as its electronic configuration is slightly different than the rest of the members. Because of their similarity in electronic configuration, [noble gas]  $ns^1$ , they are placed in the same sub group, *i.e.*, IA of the periodic table and closely resemble in their physical and chemical properties.

#### **2. Physical Properties**

(a) All the alkali elements are silvery white solids. These are soft in nature and can be cut with the help of knife except the lithium. When freshly cut, they have a bright lustre which quickly fades due to surface oxidation.

The silvery lustre of alkali metals is due to the presence of highly mobile electrons of the metallic lattice. There being only a single electron per atom, the metallic bonding is not so strong. As a result of this, these metals are soft in nature. However, the softness increases with increase of atomic number because there is continuous decrease of metallic bond strength on account of an increase in atomic size. Bigger is the size of metal kernel weaker is the metallic bonding.

- (b) Atomic and ionic radii: Group IA atoms are the largest in their horizontal periods in the periodic table. When the outermost electron is removed to give a positive ion, the size decreases considerably. There are two reasons for this:
- (i) The outermost shell of electron has been completely removed.
- (ii) The positive charge on the nucleus is now acting on lesser number of electrons, *i.e.*, attraction increases which brings contraction in size.

Atomic as well as ionic size increases from Li to Fr due to the presence of one extra shell of electrons.

Atomic volume also increases as the atomic number increases.

(c) Density: All are light metals. The densities are low. Lithium, sodium and potassium are lighter than water, for this very reason they float on water. Density gradually increases in moving down from Li to Cs. Potassium is, however, lighter than sodium.

The reason for the low values is that these metals have high atomic volumes. The abnormal value of potassium is due to unusual increase in atomic size, *i.e.*, atomic volume.

(d) Melting and boiling points: The energy binding the atoms in the crystal lattices of these metals is relatively low on account of a single electron in the valency shell. Consequently, the metals have low melting and boiling points. These decrease in moving down from Li to Cs as the metallic bond strength decreases or cohesive force decreases.

(e) Ionisation energies and electropositive character: Due to their large size, the outermost electron is far from the nucleus and can easily be removed. Their ionisation energies or ionisation enthalpies are relatively low. Thus, the metals have a great tendency to lose the  $ns^1$  electron to change into  $M^+$  ions. These metals are highly electropositive in nature. As the ionisation enthalpy decreases from Li to Cs, the electropositive character increases, *i.e.*, metallic character increases. The reactivity of these metals increases from Li to Cs.\*

<sup>\*(</sup>i) In gaseous state covalent molecules of  $M_2$  type are also known.

<sup>(</sup>ii) Cs metal has golden yellow appearance.

	Li	Na	K	Rb	Cs	
Ionisation enthalpy	520	496	419	403	376	
(kJ mol <sup>-1</sup> )		I	Decrease	s		
Electropositive or metallic nature	Increases					
Reactivity		1	Increase	s		

The ns<sup>1</sup> electron is so loosely held that even the low energy photons (light) can eject this electron from the metal surface. This property is termed as **photoelectric effect.** K and Cs are used in photoelectric cells which are sensitive to blue light.

(f) Oxidation states: The alkali metals can lose their  $ns^1$  electron quite easily to form univalent positive ion,  $M^+$ . The ion has a stable configuration of an inert gas.

Li <sup>+</sup>	He-configuration
Na <sup>+</sup>	Ne-configuration
K <sup>+</sup>	Ar-configuration
Rb <sup>+</sup>	Kr-configuration
Cs <sup>+</sup>	Xe-configuration

The energy required to pull out another electron from  $M^+$  ion is very high, *i.e.*, the second ionisation enthalpy values are high.

Consequently, it is not possible for alkali metals to form  $M^{2+}$  ions under ordinary conditions. These metals, thus show only one oxidation state, *i.e.*, +1 oxidation state. These metals are univalent in nature and show electrovalency, *i.e.*, form electrovalent compounds.

Since the electronic configuration of  $M^+$  ions are similar to those of inert gases, these ions have no unpaired electrons and consequently are **colourless** and **diamagnetic** in nature.

**(g) Hydration of ions, hydrated radii and hydration energy:** The salts of alkali metals are ionic and soluble in water. The solubility is due to the fact that cations get hydrated by water molecules.

$$M^+ + aq. \longrightarrow [M(aq.)]^+$$
Hydrated cation

The smaller the cation, the greater is the degree of its hydration. Thus, the degree of hydration of  $M^+$  ions decreases from  $\text{Li}^+$  to  $\text{Cs}^+$ . Consequently the radii of the hydrated ion decreases from  $\text{Li}^+$  to  $\text{Cs}^+$ .

The ionic conductance of these hydrated ions increases from  $[\text{Li}(aq.)]^+$  to  $[\text{Cs}(aq.)]^+$ .

$$[\text{Li}(aq.)]^+ < [\text{Na}(aq.)]^+ < [K(aq.)]^+ < [Rb(aq.)]^+ < [Cs(aq.)]^+$$
  
Ionic 33.5 43.5 64.5 67.5 68  
mobility at infinite dilution

Hydration of ions is an exothermic process. The energy released when one gram mole of an ion is dissolved in water to get it hydrated is called **hydration energy**. Since the degree of hydration decreases from Li<sup>+</sup> to Cs<sup>+</sup>, the hydration energy of alkali metal ion also decreases from Li<sup>+</sup> to Cs<sup>+</sup>.

Alkali metal ion  $Li^+$   $Na^+$   $K^+$   $Rb^+$   $Cs^+$  Hydration energy (kJ mol<sup>-1</sup>) -506 -406 -330 -310 -276

- **(h)** Electronegativity: The tendency to attract electrons is low as the alkali metals are electropositive. The electronegativity, thus, decreases from Li to Cs as the electropositive character increases.
- (i) Conductivity: The alkali metals are good conductors of heat and electricity. This is due to the presence of loosely held valency electrons which are free to move throughout the metal structure.
- (j) Specific heats: The specific heat values decrease from Li to Cs.

(k) Heat of atomisation: Heat of atomisation decreases from Li to Cs.

This is due to the decrease in the metallic bond strength from Li to Cs.

(I) Flame colouration: The alkali metals and their salts impart a characteristic colour to flame (Fig. 6.1).

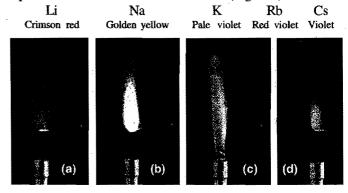

Fig. 6.1 Colour of flames of some alkali metals:
(a) Lithium (Crimson red); (b) Sodium (Golden yellow);

\_ (c) Potassium (Pale violet); (d) Rubidium (Red violet)

The reason for flame colouration is that the energy of the flame causes an excitation of the outermost electrons which on return to their original position give out the energy so absorbed in the visible region. The energy released is minimum in the case of  $Li^+$  and increases in order  $Li^+$ ,  $Na^+$ ,  $K^+$ ,  $Rb^+$ ,  $Cs^+$ . Thus, the frequency of the light emitted increases in accordance with the formula E = hv. The frequency of light in lithium is minimum which corresponds to red region of the spectra.

(m) Reducing nature: An element, which acts as a reducing agent, must have low ionisation energy. Alkali metals act as strong reducing agents as their ionisation energy values are low. Since ionisation energy decreases on moving down from Li to Cs, the reducing property increases in the same

order. Thus, Li is weakest reducing agent while Cs is the strongest reducing agent amongst alkali metals in free state.

The tendency of an element to lose an electron in solution is measured by its standard oxidation potential value  $(E_{\rm ox}^{\rm o})$ . Since alkali metals have high  $E_{\rm ox}^{\rm o}$  values, these are strong reducing agents. Because their standard oxidation potentials are so strongly positive, the alkali metals can even reduce water.

$$2\text{Na}(s) + 2\text{H}_2\text{O}(l) \longrightarrow 2\text{NaOH}(aq.) + \text{H}_2(g)$$

However, it is observed that Li is the strongest reducing agent amongst alkali metals in solution as  $E_{ox}^{o}$  value of Li is maximum.

It looks surprising at first sight that lithium having high value of ionisation energy amongst alkali metals acts as strongest reducing agent in solution. This can be explained if we understand the fact that ionisation energy is the property of an isolated atom in gaseous state while oxidation potential is concerned when the metal atom goes into the solution.

The ionisation energy involves the change of gaseous atom to gaseous ion,

$$M(g) \longrightarrow M^+(g) + e$$

while oxidation potential involves the following change:

$$M(s) \longrightarrow M^{+}(aq.) + e$$

The above change occurs in three steps:

(i) 
$$M(s) \longrightarrow M(g)$$
 – sublimation energy

(ii) 
$$M(g) \longrightarrow M^+(g) + e$$
-ionisation energy

(iii) 
$$M^+(g) + H_2O \longrightarrow M^+(aq) + hydration energy$$

Sublimation energy is nearly same for all the alkali metals.

The energy required in (ii) step is the ionisation energy which is highest for lithium. Li<sup>+</sup> ion is smallest in size, hence it has maximum degree of hydration. Thus, in (iii) step, maximum hydration energy is released in lithium.

·	Li	Na	. <b>K</b>
Step (i)	+122 kJ	+78 kJ	+61 kJ
Step (ii)	+520 kJ	+496 kJ	;+419 kJ
Step (iii)	- 506 kJ	– 406 kJ	-330  kJ
overall	136 kJ	168 kJ	150 kJ

Thus, with greater ease the following overall change occurs in lithium and it acts as a strongest reducing agent :

$$M(s) \longrightarrow M^+(aq.) + e$$

It is, therefore, concluded that highest reducing power of lithium in solution is due to its large heat of hydration.

#### 3. Chemical Properties

Alkali metals are highly reactive metals and the reasons for high reactivity are :

(i) They have low values of ionisation energies and readily lose their valence electron to form  $M^+$  ion.

- (ii) They have low heat of atomisation and easily come into vaporised form.
  - (iii) They have high heats of hydration.
- (a) Reactivity towards air: On exposure to moist air, all alkali metals except lithium tarnish quickly. The effect of atmosphere increases from Li to Cs. These are, therefore, always kept under kerosene to protect them from air.

$$\begin{array}{c} M \\ \text{Alkali metal} \xrightarrow{O_2} M_2\text{O} \xrightarrow{\text{H}_2\text{O}} M\text{OH} \xrightarrow{\text{CO}_2} M_2\text{CO}_3 \\ \text{Oxide} & \text{Hydroxide} \xrightarrow{\text{CO}_2} M_2\text{Co}_3 \\ \downarrow \text{O}_2 \\ M_2\text{O}_2 \\ \text{Peroxide} \end{array}$$

Lithium when heated in air combines with nitrogen to form nitride, it is due to diagonal relationship with magnesium.

All alkali metals react directly with most nonmetals (other than the noble gases). However, only lithium react with nitrogen, which it reduces to the nitride ion.

$$6\text{Li}(s) + \text{N}_2(g) \xrightarrow{\Delta} 2\text{Li}_3\text{N}(s)$$

**(b) Reactivity towards water:** Alkali metals decompose water with the evolution of hydrogen.

$$2M + 2H_2O \longrightarrow 2MOH + H_2\uparrow$$

Lithium decomposes water slowly. Sodium reacts with water quickly. K, Rb and Cs react with water vigorously. The decomposition is highly exothermic and the evolved hydrogen sometimes inflames. Thus, the reactivity towards water increases from Li to Cs. This is due to increase of electropositive character in the same order.

[The oxidation potential of lithium is highest amongst alkali metals, i.e., free energy released in the case of lithium is maximum ( $\Delta G = -nFE_{\rm ox}^{\rm o}$ ). In view of this, it looks rather surprising that lithium reacts gently with water whereas potassium which liberates less energy, reacts violently and catches fire. The explanation lies in the kinetics (the rate at which reaction proceeds) rather than in the thermodynamics (that is total amount of energy released). Potassium has a low melting point and heat of reaction is sufficient to make it melt or even vaporise. The molten metal spreads out and exposes a larger surface to the water, so it reacts even faster, gets even hotter and catches fire.]

The alkali metals also react with alcohols forming alkoxides with the evolution of hydrogen. This reaction is used in preliminary test of alcoholic group.

- (c) Affinity for non-metals: Alkali metals have great affinity for non-metals.
- (i) Reactivity towards hydrogen: The alkali metals combine directly with hydrogen to form crystalline hydrides of the formula MH. These hydrides are ionic and contain the hydride ion, H<sup>-</sup>.

$$2M + H_2 \longrightarrow 2MH$$

The electrolysis of the fused hydride (LiH) yields hydrogen at anode [other hydrides decompose before melting.] The hydrides react with water liberating hydrogen.

$$MH + H_2O \longrightarrow MOH + H_2\uparrow$$

The ionic character of the bonds in these hydrides increases from LiH to CsH and their stability decreases in the same order. They are powerful reducing agents especially at high temperatures.

$$SiCl_4 + 4NaH \longrightarrow SiH_4 + 4NaCl$$

(ii) Reactivity towards oxygen (oxides and hydroxides): Affinity towards oxygen increases. When heated in atmosphere of oxygen, the alkali metals ignite and form oxides. On combustion Li forms Li<sub>2</sub>O; sodium gives the peroxide, Na<sub>2</sub>O<sub>2</sub>; and potassium, rubidium and caesium give superoxides, MO<sub>2</sub>.

The normal oxides contain  $O_2^{-}$  ion, the peroxides contain  $O_2^{-}$  ion and superoxides contain  $O_2^{-}$  ion. The peroxides and superoxides become more stable with increase in atomic number of the alkali metal. The formation and stability of these oxides can be explained on the basis of lattice energy effects. Li<sup>+</sup> ion being a small ion has a strong positive field around it and can stabilise only a small anion,  $O_2^{-}$  whereas  $N_2^{+}$  being a large cation can stabilise a large ion and so on.

$$O^{2-}$$
  $[O-O-O]^{2-}$   $[O-O-O]^{2-}$   $[O-O-O-O]^{2-}$   $[O-O-O-O-O-O-O]^{2-}$  Superoxide

The normal oxides ' $M_2$ O' react with water to form hydroxides.

$$M_2O + H_2O \longrightarrow 2MOH$$

The basic nature of the oxides  $(M_2O)$  increases gradually on moving down in the group. The hydroxides (MOH) are colourless, strong alkaline and corrosive compounds. These are soluble in water and dissolve with the evolution of heat. The hydroxides are thermally stable except LiOH. The relative strength of the hydroxides increases from LiOH to CsOH.

The crystal structures of Li<sub>2</sub>O, Na<sub>2</sub>O, K<sub>2</sub>O and Rb<sub>2</sub>O are antifluorite structures. Cs<sub>2</sub>O has an anti-CdCl<sub>2</sub> layer structure.

The higher oxides, *viz.*, peroxides and superoxides are strong oxidising agents. They react with dilute acids forming hydrogen peroxide and oxygen respectively.

$$Na_2O_2 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O_2$$
  
 $4KO_2 + 2H_2SO_4 \longrightarrow 2K_2SO_4 + 2H_2O + 3O_2$   
 $2KO_2 + 2H_2O \longrightarrow 2KOH + H_2O_2 + O_2$ 

The peroxides are diamagnetic in nature (all the electrons are paired) and are regarded as the salts of the dibasic acid,  $H_2O_2$ . The superoxides are paramagnetic and coloured as odd

electron bond is present between two oxygen atoms. Yellow colour of Na<sub>2</sub>O<sub>2</sub> is probably due to the presence of small amount of superoxide. Superoxides are even stronger oxidising agents than peroxides.

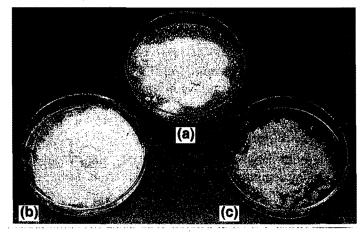

Fig. 6.2 When alkali metals react with oxygen gives different colour oxides: (a) lithium gives light colour oxides (b) sodium gives very pale yellow peroxide and (c) potassium gives yellow coloured superoxide

(iii) Reactivity towards halogens: The alkali metals directly react with halogens forming the halides of the type MX.

$$2M + X_2 \longrightarrow 2MX$$

The reactivity of alkali metals towards a particular halogen increases from Li to Cs. On the other hand, reactivity of halogens towards a particular alkali metal decreases from  $F_2$  to  $I_2$  *i.e.*,

$$F_2 > Cl_2 > Br_2 > I_2$$

With the exception of certain lithium halides, the alkali metal halides are ionic compounds  $(M^+X^-)$ . The halides are crystalline and have high melting and boiling points. The fused halides are good conductors of electricity and are used for the preparation of alkali metals. All halides except LiF dissolve in water.

Alkali metal halides are colourless but on heating they turn yellow, blue, etc., owing to non-stoichiometry and crystal defects.

Halides of potassium, rubidium and caesium have a property of combining with extra halogen atoms forming polyhalides.

$$KI + I_2 \longrightarrow KI_3$$

[The insolubility of LiF in water can be explained in the following manner. The lithium ion has the highest energy of hydration as it is small in size in comparison to other alkali metal ions and thus it should have high solubility. However, the small Li<sup>+</sup> and F<sup>-</sup> ions interact very strongly resulting in high lattice energy of LiF which is responsible for its insolubility (the ionic compounds, which possess low value of lattice energy, are freely soluble in water).]

(iv) Action with sulphur and phosphorus: Alkali metals directly combine with sulphur and phosphorus when heated with them. The monosulphides,  $M_2S$ , cannot be obtained by

passing H<sub>2</sub>S through their salt solutions as sulphides get hydrolysed.

$$M_2S + H_2O \implies MOH + MHS$$

Phosphides on hydrolysis evolve phosphine.

$$3M + P \longrightarrow M_3P$$
  
 $M_3P + 3H_2O \longrightarrow 3MOH + PH_3$ 

- (d) Nature of oxysalts: Alkali metals readily react with oxyacids forming corresponding salts with evolution of hydrogen. Lithium salts behave abnormally due to polarising power of Li<sup>+</sup>ion (small size) and lattice energy effects. However, the salts of rest of the alkali metals behave similarly and there is a gradual gradation in their properties with the increase of atomic number.
- (i) Nature of carbonates and bicarbonates: All the alkali metals form carbonates of the type  $M_2\text{CO}_3$ . Since the alkali metals are highly electropositive, their carbonates are highly stable towards heat and readily soluble in water. As the electropositive character increases from Li to Cs, the stability of the carbonates increases in the same order.

$$Cs_2CO_3 > Rb_2CO_3 > K_2CO_3 > Na_2CO_3 > Li_2CO_3$$

Li<sub>2</sub>CO<sub>3</sub> decomposes on heating and is insoluble in water. The aqueous solutions of carbonates are alkaline. This is due to hydrolysis as carbonates are salts of strong bases and weak acid (H<sub>2</sub>CO<sub>3</sub> carbonic acid).

$$M_2\text{CO}_3 + 2\text{H}_2\text{O} \Longrightarrow 2M\text{OH} + \text{H}_2\text{CO}_3$$
  
Strong alkali Weak acid

The bicarbonates, MHCO<sub>3</sub>, of the alkali metals, with the exception of lithium, are known in solid state. The bicarbonates are soluble in water. On heating, bicarbonates decompose into carbonates with evolution of CO<sub>2</sub>.

$$2MHCO_3 \longrightarrow M_2CO_3 + H_2O + CO_2$$

The abnormal behaviour of Li<sub>2</sub>CO<sub>3</sub> towards heat can be explained in the following manner.

The Li<sup>+</sup> ion exerts a strong polarising action and distorts the electron cloud of the nearby oxygen atom of the large CO<sub>3</sub><sup>2</sup> ion. This results in the weakening of the C—O bond and strengthening of the Li—O bond. This ultimately facilitates the decomposition of Li<sub>2</sub>CO<sub>3</sub> into Li<sub>2</sub>O and CO<sub>2</sub>. The lattice energy of Li<sub>2</sub>O is higher than the lattice energy of carbonate. This also favours the decomposition of Li<sub>2</sub>CO<sub>3</sub>.

Lithium due to its less electropositive nature, does not form solid bicarbonate.

(ii) Nature of nitrates: Nitrates of the type, MNO<sub>3</sub>, are known. These are colourless, soluble in water and electrovalent in nature. The nitrates do not undergo hydrolysis. With the exception of LiNO<sub>3</sub>, the other nitrates decompose to nitrites and oxygen.

$$2MNO_3 \longrightarrow 2MNO_2 + O_2$$

Lithium nitrate decompose to oxide on heating, it is due to diagonal relationship with magnesium.

$$2\text{LiNO}_3 \longrightarrow \text{Li}_2\text{O} + 2\text{NO}_2 + \frac{1}{2}\text{O}_2$$

(iii) Nature of sulphates: Sulphates of the type  $M_2SO_4$  are known. With the exception of  $Li_2SO_4$ , other sulphates are soluble in water. The sulphates when fused with carbon form sulphides.

$$M_2SO_4 + 4C \longrightarrow M_2S + 4CO$$

The sulphates of alkali metals form double salts with the sulphates of the trivalent metals like Fe, Al, Cr, etc. The double sulphates crystallise with large number of water molecules as potash alum,  $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$  consists of 24 water molecules. Sulphate of lithium is not known to form alum.

(iv) Nature of perchlorates: Perchlorates of the type  $MClO_4$  are known. The stability increases gradually as larger  $M^+$  ion form more stable lattice with large  $ClO_4^-$  ion. The solubility of perchlorates decreases.

$$LiClO_4 > NaClO_4 > KClO_4 > RbClO_4 > CSClO_4$$

LiClO<sub>4</sub> is ten times more soluble than NaClO<sub>4</sub>. It is mainly due to extensive solvation of smaller Li<sup>+</sup>.

(e) Solubility in liquid ammonia: The alkali metals dissolve in liquid ammonia without the evolution of hydrogen. The colour of the dilute solutions is blue. The metal atom loses electron and it combines with ammonia molecule.

$$M \longrightarrow M^+$$
 (in liquid ammonia) + e (ammoniated)  
 $M + (x + y)NH_3 \longrightarrow [M(NH_3)_x]^+ + e (NH_3)_y$   
Solvated electron

On heating its blue colour changes to bronze.

It is ammoniated electron which is responsible for colour. The solutions are good conductors of electricity and have strong reducing properties. The solutions are paramagnetic in nature.

When dry ammonia is passed over hot metal, amides are formed.

$$2M + 2NH_3 \longrightarrow 2MNH_2 + H_2 \uparrow$$
Amide

The amides are decomposed by cold water with evolution of  $NH_3$ .

$$MNH_2 + H_2O \longrightarrow MOH + NH_3$$

Recent studies proved the existence of Li(NH<sub>3</sub>)<sub>4</sub>, a golden yellow solid.

- (f) Formation of alloys: The alkali metals form alloys amongst themselves and with other metals. These combine with mercury readily forming amalgams.
- (g) Complex formation: Alkali metals have a very little tendency to form complexes. Lithium being small in size forms certain complexes but this tendency decreases as the size increases.
- (i) Extraction of alkali metals: Alkali metals cannot be extracted by the application of common processes used for the extraction of metals due to following reasons:
- (i) Alkali metals are strong reducing agents, hence cannot be extracted by reduction of their oxides and other compounds.
- (ii) Being highly electropositive in nature, it is not possible to apply the method of displacing them from their salt solutions by any other element.

(iii) The aqueous solutions of their salts cannot be used for extraction by electrolytic method because hydrogen is discharged at cathode instead of an alkali metal as the discharge potentials of alkali metals are high. However, by using Hg as cathode, alkali metal can be deposited. The alkali metal readily combines with Hg to form an amalgam from which its recovery is very difficult.

The only successful method, therefore, is the electrolysis of their fused salts, usually chlorides. Generally, another metal chloride is added to lower its fusion temperature.

### 6.2 ABNORMAL BEHAVIOUR OF LITHIUM

The lithium, being the first member of alkali group, exhibits the characteristic properties of alkali metals but it differs at the same time in many respects from them. Reasons for its abnormal behaviour are mainly due to the following reasons:

- (i) Lithium atom and its ion has very small size. Lithium ion (Li<sup>+</sup>) on account of its small size exerts high polarising effect on anions in its compounds resulting in increased covalent character.
- (ii) Lithium atom has highest ionisation enthalpy and low electropositive character as compared to other alkali metals.
  - (iii) Nonavailability of *d*-orbitals in its valence shell.
- (iv) Lithium has strong metallic bonding which is responsible for its low reactivity to some extent.

## Lithium differs from alkali metals in the following respects:

- (i) It is more harder and lighter than other alkali metals.
- (ii) It is not affected by air easily and does not lose its lustre even on melting.
  - (iii) It reacts slowly with water to liberate hydrogen.
- (iv) It does not react with oxygen below 0°C. When burnt in air or oxygen, it forms only monoxide, Li<sub>2</sub>O. However, the rest of the alkali metals give peroxides or superoxides. Li<sub>2</sub>O is much less basic than oxides of other alkali metals.
- (v) Lithium is the only alkali metal which directly reacts with nitrogen to form Li<sub>3</sub>N.
- (vi) Lithium hydroxide decomposes at red heat to form Li<sub>2</sub>O. Hydroxides of other alkali metals donot decompose.

$$2\text{LiOH} \longrightarrow \text{Li}_2\text{O} + \text{H}_2\text{O}$$

- (vii) Lithium bicarbonate, LiHCO<sub>3</sub> is known in solution but not in solid state while the bicarbonates of other alkali metals are known in solid state.
  - (viii) Li<sub>2</sub>CO<sub>3</sub> is less stable, as it decomposes on heating.

$$\text{Li}_2\text{CO}_3 \longrightarrow \text{Li}_2\text{O} + \text{CO}_2$$

The other carbonates are stable.

(ix) LiNO<sub>3</sub>, on heating gives a mixture of  $NO_2$  and  $O_2$  while nitrates of rest of alkali metals yield only oxygen.

$$4\text{LiNO}_3 \longrightarrow 2\text{Li}_2\text{O} + 4\text{NO}_2 + \text{O}_2$$
  
 $2\text{NaNO}_3 \longrightarrow 2\text{NaNO}_2 + \text{O}_2$ 

(x) Li<sub>2</sub>SO<sub>4</sub> is the only alkali metal sulphate which does not form double salts, *e.g.*, alums.

- (xi) Lithium reacts with bromine very slowly. Other alkali metals react violently.
- (xii) Lithium fluoride (LiF), lithium phosphate (Li<sub>3</sub>PO<sub>4</sub>), lithium oxalate (Li<sub>2</sub>C<sub>2</sub>O<sub>4</sub>), lithium carbonate (Li<sub>2</sub>CO<sub>3</sub>), etc., are sparingly soluble in water. The corresponding salts of other alkali metals are freely soluble in water.
- (xiii) LiCl is highly deliquescent and soluble in alcohol and pyridine. LiCl separates out from aqueous solution as hydrated crystals LiCl·2H<sub>2</sub>O whereas chlorides of other alkali metals are insoluble in organic solvents and do not form hydrated crystals under ordinary temperatures.
- (xiv) Li when heated in  $NH_3$  forms imide  $Li_2NH$  while other alkali metals form amides,  $MNH_2$ .
  - (xv) LiOH is much weaker base than NaOH or KOH.

# DIAGONAL RELATIONSHIP : SIMILARITIES WITH MAGNESIUM

Lithium shows resemblance with magnesium, an element of group IIA. This resemblance is termed as **diagonal relationship**.

#### Reasons for the diagonal relationship are the following:

- (i) Electronegativities of Li and Mg are quite comparable. (Li = 1.00, Mg = 1.20)
- (ii) Atomic radii and ionic radii of Li and Mg are not very much different.

(iii) Atomic volumes of Li and Mg are quite similar.

(iv) Both have high polarising power (ionic potential)

Polarising power 
$$(\Phi) = \frac{\text{Ionic charge}}{(\text{Ionic radius})^2}$$

Cations with large ionic potentials have a tendency to polarise the anions and to give partial covalent character to compounds.

Lithium resembles magnesium in the following respects:

- (a) Both Li and Mg are harder and have higher melting points than the other metals in their respective groups.
  - (b) Li like Mg decomposes water slowly to liberate hydrogen.

$$2\text{Li} + 2\text{H}_2\text{O} \longrightarrow 2\text{LiOH} + \text{H}_2$$
  
 $\text{Mg} + 2\text{H}_2\text{O} \longrightarrow \text{Mg(OH)}_2 + \text{H}_2$ 

(c) Both the elements combine with nitrogen on heating.

$$\begin{array}{ccc} 6\text{Li} & + & N_2 & \longrightarrow & 2\text{Li}_3N \\ 3\text{Mg} & + & N_2 & \longrightarrow & \text{Mg}_3N_2 \end{array}$$

Both the nitrides are decomposed by water with evolution of ammonia (NH<sub>3</sub>).

$$\text{Li}_3\text{N} + 3\text{H}_2\text{O} \longrightarrow 3\text{LiOH} + \text{NH}_3$$
  
 $\text{Mg}_3\text{N}_2 + 6\text{H}_2\text{O} \longrightarrow 3\text{Mg}(\text{OH})_2 + 2\text{NH}_3$ 

(d) Both Li and Mg combine with carbon on heating.

$$2Li + 2C \longrightarrow Li_2C_2$$

$$Mg + 2C \longrightarrow MgC_2$$

Both the carbides yield C<sub>2</sub>H<sub>2</sub> with water.

(e) Lithium forms only monoxide when heated in oxygen. Mg also forms the monoxide.

$$4Li + O_2 \longrightarrow 2Li_2O$$
  
 $2Mg + O_2 \longrightarrow 2MgO$ 

Both the oxides are less soluble in water.

(f) Hydroxides of Li and Mg are weak bases and are slightly soluble in water. Both decompose on heating.

- (g) Lithium fluoride, phosphate, oxalate and carbonate, like the corresponding salts of Mg, are sparingly soluble in water.
  - (h) Carbonates of Li and Mg decompose on heating.

$$Li_2CO_3 \longrightarrow Li_2O + CO_2$$
  
 $MgCO_3 \longrightarrow MgO + CO_2$ 

(i) Nitrates of Li and Mg decompose on heating giving mixture of nitrogen dioxide and oxygen.

$$4\text{LiNO}_3 \longrightarrow 2\text{Li}_2\text{O} + 4\text{NO}_2 + \text{O}_2$$
  
 $2\text{Mg(NO}_3)_2 \longrightarrow 2\text{MgO} + 4\text{NO}_2 + \text{O}_2$ 

- (j) Chlorides of both Li and Mg are deliquescent and soluble in alcohol and pyridine. Lithium chloride like magnesium chloride, (MgCl<sub>2</sub>·6H<sub>2</sub>O) separates out from solutions as hydrated crystals, LiCl·2H<sub>2</sub>O.
- (k) Li<sub>2</sub>SO<sub>4</sub> like MgSO<sub>4</sub> does not form double sulphates, *i.e.*, alums.
- (l) The bicarbonates of Li and Mg do not exist in solid state, they exist in solutions only.
  - (m) Lithium salts like magnesium salts undergo hydrolysis.
  - (n) Alkyls of Li and Mg are soluble in organic solvents.

#### **Example 1.** Explain the following:

- (a) The softness of group IA metals increases down the group with increasing atomic number. [HT 1986]
- (b) Lithium salts have a greater degree of covalent character than other halides of the group.
- (c) Li<sup>+</sup> ion is far smaller than the other alkali metal ions but it moves through a solution less rapidly than the others.
- (d) Lithium fluoride has the lowest solubility of the group IA metal halides.
- (e) Salts of lithium having small anions are more stable than the salts having larger anions.

**Solution:** (a) The metallic bond strength is low in the case of alkali metals as only one electron per large sized metal

atom is available. Thus, alkali metals are soft in nature. However, the size of the metal ion increases with increasing atomic number, the metallic bond strength decreases and, therefore, softness increases.

- (b) The small size of Li<sup>+</sup> gives it a huge polarising power. The electron cloud of larger halide ion gets distorted and this leads to covalency.
- (c) The dense charge of Li<sup>+</sup> attracts several layers of water molecules around it, *i.e.*, Li<sup>+</sup> has maximum degree of hydration. Thus, the size of the hydrated lithium ion is largest in comparison to the size of the other hydrated metal ions which affects its movement in solution.
- (d) The small size of both the Li<sup>+</sup> and F<sup>-</sup> ions leads to a very large lattice energy and thus, the crystal is very hard to break apart.
- (e) The salts of Li<sup>+</sup> with small anions have high lattice energy and thus very stable while with large anion, the lattice energy decreases and the salts become less stable.

#### **Example 2.** Explain the following:

- (a) Alkali metals do not occur free in nature.
- (b) Alkali metals are good reducing agents.
- (c) Alkali metal salts impart colour to the flame.

[Roorkee 1986]

- (d) Sodium is kept under kerosene.
- (e) Potassium and caesium are used in photoelectric cells.

**Solution:** (a) Since the ionisation potential values of alkali metals are low, they are very reactive in nature. They readily combine with oxygen, moisture and  $CO_2$  of the atmosphere and many other substances. Hence, they do not occur free in nature.

- (b) Alkali metals act as strong reducing agents because they can lose valency electrons easily on account of low ionisation potential values and high values of oxidation potentials.
- (c) The energy of the flame causes an excitation of the outermost electron which on return to its original position gives out energy so absorbed in the visible region. The amount of energy released increases from Li<sup>+</sup> to Cs<sup>+</sup>. Thus, the frequency of light emitted increases in accordance with the formula E = hv. The frequency of light is minimum in lithium which corresponds to red light.
- (d) Sodium is highly electropositive and hence is very reactive. It readily combines with oxygen, moisture and CO<sub>2</sub> of the atmosphere. Hence, it is always kept in kerosene as to prevent the action of atmosphere.
- (e) Because of low ionisation potentials, potassium and caesium are used in photoelectric cells. The low energy photons (light) can eject electrons from their metal surface.

#### 6.3 LITHIUM

**Occurrence:** Lithium is rare but is widely distributed in the earth's crust. Its amount present in any mineral is generally

low and, thus, its extraction is somewhat difficult. Important minerals of lithium are:

- (a) Aluminosilicates: These include the following minerals.
- (i) Lepidolite or lithiamica, (Li, Na, K)<sub>2</sub>·Al<sub>2</sub>(SiO<sub>3</sub>)<sub>3</sub>(F, OH)<sub>2</sub>. It contains 2-6% lithium.
  - (ii) Spodumene, LiAl(SiO<sub>3</sub>)<sub>2</sub>. It contains 3.8 to 5.6% lithium.
  - (iii) Petalite, LiAl(Si<sub>2</sub>O<sub>5</sub>)<sub>2</sub>. It contains 2 to 3% lithium.
  - (b) Phosphates: These include the following minerals:
- (i) Triphylite, (Li, Na)<sub>3</sub>PO<sub>4</sub> (Fe, Mn)<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>. It is a double phosphate and contains about 1.5 to 3.5% lithium.
- (ii) Amblygonite, Li(AlF)PO<sub>4</sub>. It contains 7 to 10% lithium. Lithium occurs in traces in soils, sea water, certain spring waters, blood, muscular tissues and ashes of some plants such as sugar cane, beat, tobacco, coffee, etc.

Lithium occurs in India mainly as lepidolite in Bihar, Kashmir, Karnataka and Rajasthan.

**Extraction:** The extraction of lithium from any one of the minerals involves two steps:

- (i) Preparation of lithium chloride from the mineral.
- (ii) Electrolysis of lithium chloride.

#### (i) Preparation of Lithium Chloride, LiCI

(a) From lepidolite: The powdered mineral is fused with a mixture of barium carbonate, barium sulphate and potassium sulphate. In fused state, two layers are separated. The upper layer contains sulphates of lithium, sodium and potassium while the lower layer contains heavier materials such as silicates, barium sulphate, aluminium sulphate, alumina, silica, etc.

The upper layer is dissolved in minimum quantity of water and then the solution is treated with barium chloride. The sulphates of Li, Na and K react and form corresponding soluble chlorides and insoluble barium sulphate with barium chloride.

$$\text{Li}_2\text{SO}_4 + \text{BaCl}_2 \longrightarrow 2\text{LiCl} + \text{BaSO}_4$$
  
 $\text{Na}_2\text{SO}_4 + \text{BaCl}_2 \longrightarrow 2\text{NaCl} + \text{BaSO}_4$   
 $\text{K}_2\text{SO}_4 + \text{BaCl}_2 \longrightarrow 2\text{KCl} + \text{BaSO}_4$ 

The insoluble barium sulphate is removed by filtration. The solution containing chlorides of Li, Na and K is evaporated to dryness. LiCl is extracted from the solid residue with the help of pyridine. LiCl dissolves in pyridine while other chlorides remain insoluble. From the pyridine solution, LiCl is recovered by distillation.

(b) From triphylite ore (phosphate ore): The powdered ore is digested with conc. HCl. H<sub>3</sub>PO<sub>4</sub> comes into the solution along with chlorides of Li, Na, Mn and Fe. The phosphate is removed from the solution in the same manner as it is done in qualitative analysis. The solution is neutralised with NH<sub>4</sub>OH and then a buffer solution containing CH<sub>3</sub>COOH and CH<sub>3</sub>COONa is added. Now neutral FeCl<sub>3</sub> solution is added when FePO<sub>4</sub> gets precipitated. It is filtered off.

$$H_3PO_4 + FeCl_3 \longrightarrow FePO_4 + 3HCl$$

The filtrate is evaporated to dryness and the solid residue is extracted with hot water. Mn is removed as MnS by the addition of BaS.

$$MnCl_2 + BaS \longrightarrow MnS + BaCl_2$$

 $MnCl_2 + BaS \longrightarrow MnS + BaCl_2$ The filtrate is now treated with  $H_2SO_4$  to remove barium as barium sulphate.

$$BaCl_2 + H_2SO_4 \longrightarrow BaSO_4 + 2HCl$$
  
 $BaS + H_2SO_4 \longrightarrow BaSO_4 + H_2S$ 

The filtrate containing Li<sub>2</sub>SO<sub>4</sub> and Na<sub>2</sub>SO<sub>4</sub> is evaporated with oxalic acid. The oxalates of lithium and sodium formed, on ignition give corresponding carbonates.

$$Li_2SO_4 + H_2C_2O_4 \longrightarrow Li_2C_2O_4 + H_2SO_4$$

$$Li_2C_2O_4 \longrightarrow Li_2CO_3 + CO$$

$$Na_2C_2O_4 \longrightarrow Na_2CO_3 + CO$$

The carbonates on treatment with HCl give their chlorides. LiCl is extracted from the mixture with pyridine.

#### (ii) Electrolysis of LiCl

Lithium is obtained by the electrolysis of a fused mixture of lithium chloride and potassium chloride in equal amounts. The addition of potassium chloride serves the following purposes:

- (i) It increases the conductivity of the fused mass.
- (ii) It lowers the fusion temperature of lithium chloride.

The electrolysis is carried out in a steel vessel with refractory lining inside. The cell is fitted with a graphite anode and a steel cathode which is surrounded by cast iron enclosure so that lithium and chlorine formed during electrolysis may not come in contact with each other (Fig. 6.3).

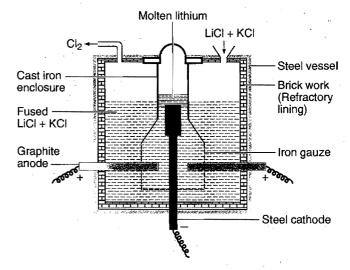

Fig. 6.3 Electrolysis of lithium chloride

The cell is operated at a voltage of 8-9 volt at 400-450°C temperature. When electric current is passed, lithium ions, in preference to potassium ions, get discharged at cathode while chloride ions are discharged at anode.

At cathode,  $Li^+ + e \longrightarrow Li$ 

$$2Cl^- \longrightarrow Cl_2 + 2e^-$$

The molten lithium containing about 1.3% of potassium, being lighter, rises to the surface of the fused electrolyte in the cast iron enclosure. The metal is removed intermittently and stored either in well stoppered bottles or in liquids like ether, petrol, etc.

#### **■** Properties

**Physical:** (i) It is a silvery white metal. It is harder than sodium and potassium. It has two naturally occurring isotopes <sup>6</sup>Li and <sup>7</sup>Li. <sup>7</sup>Li is most stable isotope. <sup>6</sup>Li is used as tritium source in thermonuclear reactions.

$${}_{3}^{6}\text{Li} + {}_{0}^{1}n \longrightarrow {}_{1}^{3}\text{H} + {}_{2}^{4}\text{He}$$

- (ii) It is very light. It's density is 0.534 at 20°C which is the lowest of all metals.
- (iii) It melts at 180.5°C. When volatilized it imparts red colour to flame. Its boiling point is 1347°C.
- (iv) It is a good conductor of heat and electricity. It has the highest specific heat (0.96).
- (v) It forms an amalgam and alloys with a number of other metals. An alloy of composition, Li = 1.1%, Cu = 4.5%, Mn=0.5%, Cd=0.2% and rest Al is used in aircraft construction.

**Chemical:** (i) Reactivity towards air: Lithium is not affected by dry air but is oxidised when moisture is present. When heated in air above 180°C, it burns with brilliant light forming lithium oxide and lithium nitride.

$$4\text{Li} + \text{O}_2 \longrightarrow 2\text{Li}_2\text{O}$$
 (Lithium oxide)  
 $6\text{Li} + \text{N}_2 \longrightarrow 2\text{Li}_3\text{N}$  (Lithium nitride)

(ii) Reactivity towards water: Lithium reacts with water forming lithium hydroxide and liberating hydrogen. However, the reaction is not vigorous due to high melting point.

$$2Li + 2H_2O \longrightarrow 2LiOH + H_2\uparrow$$

- (iii) The oxidation potential of lithium is high, i.e., + 3.04 volt. Thus, it acts as a strong reducing agent in solution.
- (iv) Reactivity towards non-metals: Lithium combines with a number of non-metals and form stable compounds. The reaction usually occurs when lithium is heated above its fusion point. These compounds are ionic in nature and their stability is due to the fact that a small lithium cation is held by a small anion.

$$\begin{array}{lll} 2 \text{Li} + \text{H}_2 & \longrightarrow 2 \text{LiH} \\ 6 \text{Li} + \text{N}_2 & \longrightarrow 2 \text{Li}_3 \text{N} \\ 4 \text{Li} + \text{O}_2 & \longrightarrow 2 \text{Li}_2 \text{O} \\ 2 \text{Li} + \text{S} & \longrightarrow \text{Li}_2 \text{S} \\ 3 \text{Li} + \text{P} & \longrightarrow \text{Li}_3 \text{P} \\ 2 \text{Li} + 2 \text{C} & \longrightarrow \text{Li}_2 \text{C}_2 \\ 2 \text{Li} + X_2 & \longrightarrow 2 \text{LiX} \end{array} \end{aligned} \begin{tabular}{ll} \text{(Lithium hydride)} \\ \text{(Lithium oxide)} \\ \text{(Lithium sulphide)} \\ \text{(Lithium phosphide)} \\ \text{(Lithium carbide)} \\ \text{(Lithium halide)} \\ \text{(Lithium halide)} \\ \text{(X = F, Cl, Br or I)} \\ \end{tabular}$$

Except LiF, all other halides show somewhat covalent nature as the small Li<sup>+</sup> cation brings more and more polarisation (distortion) in the molecule as the size of the halide ion,  $X^-$ , increases.

(v) Reactivity towards acids: Lithium, being strongly electropositive, reacts with dilute and conc. HCl and dilute  $H_2SO_4$  (non-oxidising acids) liberating hydrogen.

$$2\text{Li} + 2\text{HCl} \longrightarrow 2\text{LiCl} + \text{H}_2 \uparrow$$
  
 $2\text{Li} + \text{H}_2 \text{SO}_4 \longrightarrow \text{Li}_2 \text{SO}_4 + \text{H}_2 \uparrow$ 

However, the reaction with conc. H<sub>2</sub>SO<sub>4</sub> is slow. HNO<sub>3</sub> attacks lithium violently. The metal melts and catches fire.

$$2\text{Li} + 2\text{HNO}_3 \longrightarrow 2\text{LiNO}_3 + \text{H}_2 \uparrow$$

The oxy-salts are not stable towards heat and decompose on heating forming stable monoxide, Li<sub>2</sub>O.

$$2\text{LinO}_3 \longrightarrow \text{Li}_2\text{O} + 2\text{NO}_2 + \left(\frac{1}{2}\right)\text{O}_2$$
  
 $\text{Li}_2\text{CO}_3 \longrightarrow \text{Li}_2\text{O} + \text{CO}_2$ 

- (vi) Reactivity towards alkalies: Alkalies have no action on lithium.
- (vii) Reactivity towards ammonia: Lithium reacts with ammonia when passed over hot metal to yield H<sub>2</sub>.

$$\begin{array}{ccc} 2Li + NH_{3} & \longrightarrow & Li_{2}NH & + H_{2} \\ & & & \text{(Lithium imide)} \end{array}$$

However, lithium dissolves in liquid ammonia and forms blue coloured solution.

(viii) Lithium forms a number of alkyls and aryls. These compounds are formed from the alkyl or aryl halides, usually the chloride, in the solvent such as ether, cyclohexane or toluene.

$$RCI + 2Li \longrightarrow LiR + LiCI$$

These compounds are usually tetrameric,  $(LiCH_3)_4$ , or hexameric,  $(LiC_2H_5)_6$ . These lithium alkyls or aryls are used in the preparation of organometallic and organic compounds.

$$\begin{array}{c} \text{Li}R + \text{CO}_2 \longrightarrow R \text{COOH} + \text{LiOH} & \text{(carboxylic acids)} \\ \text{Li}R + \text{Cl}_2 \longrightarrow R \text{--Cl} + \text{LiCl} & \text{(alkyl/aryl halide)} \\ 2\text{Li}R + 3\text{CO} \longrightarrow R_2 \text{CO} + 2\text{LiCO} & \text{(ketones)} \\ 3\text{Li}R + \text{BCl}_3 \longrightarrow \text{B}R_3 + 3\text{LiCl} & \text{(organoboron compound)} \\ 4\text{Li}R + \text{SnCl}_4 \longrightarrow \text{Sn}R_4 + 4\text{LiCl} & \text{(organotin compound)} \\ 2\text{Li}R + \text{HgI}_2 \longrightarrow \text{Hg}R_2 + 2\text{LiI} & \text{(organomercury compound)} \\ \end{array}$$

#### Uses

- (i) In the refining of metals: Lithium is used as deoxidiser in the purification of nickel and copper. It removes the last traces of oxygen and nitrogen.
- (ii) In the preparation of useful alloys: Lithium is used in the manufacture of a number of alloys. It increases tensile strength and resistance to corrosion.
- (a) Lead-lithium alloy is used for making bearings for motor engines.

- (b) Aluminium-lithium alloy is used to make aircraft parts which are light and strong.
  - (c) Magnesium-lithium alloy is used to make armour-plate.
- (iii) Thermonuclear purposes: There is a great interest in lithium for thermonuclear purposes, since when bombarded with neutrons, it produces tritium.

$${}_{3}^{6}\text{Li} + {}_{0}^{1}n \longrightarrow {}_{1}^{3}\text{H} + {}_{2}^{4}\text{He}$$

$${}_{3}^{7}\text{Li} + {}_{0}^{1}n \longrightarrow {}_{1}^{3}\text{H} + {}_{2}^{4}\text{He} + {}_{0}^{1}n$$

It is also used in the production of thermonuclear energy required for propelling rockets and missiles.

- (iv) Lithium batteries: Lithium batteries are used wherever a reliable current is required for a lengthy period. Pacemaker battery is a type of lithium battery. Lithium is used to make both primary and secondary batteries. Primary batteries have Li-anodes, carbon cathodes and SOCl<sub>2</sub> as an electrolyte. It is strongly favoured to replace the lead-acid battery for electric vehicle propulsion.
  - (v) Lithium compounds have a number of applications:
- (a) Lithium hydroxide is used in the production of lithium soaps, which are used in making lubricating greases from oil (lithium soap thickens the oil). More than 60 per cent of all automotive greases contain lithium. The compound used is lithium stearate, C<sub>17</sub>H<sub>35</sub>COOLi, which is mixed with oil to give a water resistant grease-like material that does not harden at cold temperatures and also stable at high temperatures.
- (b) Lithium aluminium hydride, LiAlH<sub>4</sub>, is used as a reducing agent in organic chemistry.
- (c) Lithium carbonate (Li<sub>2</sub>CO<sub>3</sub>), which is obtained from lithium ore, is the primary source of other lithium compounds. Lithium carbonate is also used in the preparation of special type of glass. It increases the strength and resistance of glass. Significant quantities of lithium carbonate are also used in the preparation of porcelain, enamels and glazes.
  - (d) Lithium chloride is used in air-conditioning plants.
- (e) Lithium bicarbonate, lithium salicylate, lithium acetyl salicylate, etc., are used in medicines.
- (f) Lithium alkyls/aryls are used in the preparation of organometallic compounds. Butyllithium, LiC<sub>4</sub>H<sub>9</sub>, is a useful reagent in organic chemistry.
- (g) Lithium compounds have been used in the synthesis of vitamin-A and some pharmaceuticals.
- (h) Lithium salts are used in ceramics to prevent surface cracking of pottery.
- (i) Lithium hydroxide is used to remove carbon dioxide from air in spacecraft and submarine.

#### 6.4 SODIUM

Sodium is soft, silvery-grey, most abundant alkali metal. It can be cut easily with a sharp knife (Fig. 6.4). It forms 2.27% of the earth's crust. It was isolated by Sir Humphry Davy in 1807 by the electrolysis of fused caustic soda. Being reactive, it is

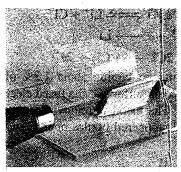

Fig. 6.4 Elemental sodium is a soft metal that can be cut easily with a knife.

never found free in nature. The most important compound of sodium found in nature is the common salt (NaCl). It is also known as lake salt, rock salt, sea salt, common salt or table salt. Sea water contains 2.0–2.9% sodium chloride. Sodium metal as well as other sodium compounds are produced from sodium chloride. Other important compounds of sodium found in nature are:

- (i) Chile saltpetre, NaNO3
- (ii) Glauber's salt, Na<sub>2</sub>SO<sub>4</sub>·10H<sub>2</sub>O
- (iii) Trona, Na<sub>2</sub>CO<sub>3</sub>·2NaHCO<sub>3</sub>·3H<sub>2</sub>O
- (iv) Natron, Na<sub>2</sub>CO<sub>3</sub>·H<sub>2</sub>O
- (v) Tincal (Borax), Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O
- (vi) Cryolite, Na<sub>3</sub>AlF<sub>6</sub>
- (vii) Soda feldspar, NaAlSi<sub>3</sub>O<sub>8</sub>

#### **■** Preparation

Sodium is obtained on large scale by two processes:

- (i) Castner's process
- (ii) Down's process
- (i) Castner's process: In this process, electrolysis of fused sodium hydroxide is carried out at 330°C using iron as cathode and nickel as anode.

$$2\text{NaOH} \implies 2\text{Na}^+ + 2\text{OH}^-$$

At cathode:  $2Na^+ + 2e \longrightarrow 2Na$ 

At anode: 
$$4OH^- \longrightarrow 2H_2O + O_2 + 4e$$

During electrolysis, oxygen and water are produced. Water formed at the anode gets partly evaporated and is partly broken down and hydrogen is discharged at cathode.

$$H_2O \rightleftharpoons H^+ + OH^-$$

At cathode:  $2H^+ + 2e \longrightarrow 2H \longrightarrow H_2 \uparrow$ 

(ii) Down's cocess: Now-a-days sodium metal is manufactured by this process. It involves the electrolysis of fused sodium chloride containing calcium chloride and potassium fluoride using iron as cathode and graphite as anode at about 600°C, the melting point of the mixture.

Sodium chloride, obtained from rock salt or sea water, is mixed with calcium chloride and melted. The calcium chloride is added to the sodium chloride electrolyte to reduce the working temperature of the cell from 801°C (the melting point of sodium chloride) to 600°C (the melting point of the mixture). This saves electrical energy and, therefore, makes the process more economical.

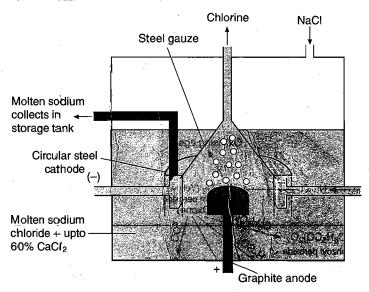

Fig. 6.5 The Down's cell used for the electrolysis of sodium chloride

The cathode is a circle of steel around the graphite anode. At 600°C sodium and chlorine would react violently together to re-form sodium chloride. To prevent this from happening, the Down's cell contains a steel gauze around the graphite anode to keep it and the cathode apart. The molten sodium float on the electrolyte and is run off for storage. A problem arises, however, is that the calcium ions are also attracted to the cathode, where they form calcium metal. Therefore, the sodium which is run off contains a significant amount of calcium. Fortunately, the calcium crystallises out when the mixture cools and relatively pure sodium metal remains.

The worldwide production of sodium metal each year is about 60,000 to 80,000 tonnes.

The overall reaction which takes place in the cell is,

$$NaCl \rightleftharpoons Na^+ + ^1Cl^-$$

At cathode:  $Na^+ + e \longrightarrow Na$ 

At anode:  $2Cl^- \longrightarrow Cl_2 + 2e$ 

The electrolysis of pure NaCl presents the following difficulties:

- (a) The fusion temperature of NaCl is high, *i.e.*, 801°C. At this temperature both sodium and chlorine are corrosive.
  - (b) Sodium forms a metallic fog at this temperature.

To remove above difficulties, the fusion temperature is reduced from 801°C to 600°C by adding CaCl<sub>2</sub> and KF. This is a cheaper method and chlorine is obtained as a byproduct.

#### Properties

**Physi il Properties:** (a) It is a silvery white metal when freshly cut but the surface is readily tarnished on exposure. The most stable isotope of sodium is  $^{23}_{11}$ Na. Many radioactive isotopes of sodium such as  $^{20}_{11}$ Na,  $^{21}_{11}$ Na,  $^{22}_{11}$ Na,  $^{24}_{11}$ Na,  $^{25}_{11}$ Na are known. Among these  $^{24}_{11}$ Na has shortest half life (0.02 seconds).

- (b) It is soft in nature and lighter than water.
- (c) It is malleable and ductile in nature.
- (d) It is good conductor of heat and electricity.
- (e) It has low melting point. It melts at a temperature of only 371 K or 97.8°C (Just below the normal boiling point of water) and its boiling point is 1156 K.
  - (f) With mercury, it forms an amalgam.
- (g) It dissolves in liquid ammonia forming intense blue coloured solution.
- (h) It gives two bright lines  $D_1$  (589.2 nm) and  $D_2$  (590.4 nm) in the yellow region of spectrum.

**Chemical Properties:** (a) Reactivity towards air: On keeping it in the moist atmosphere, it loses its lustre on account of the formation of oxide, hydroxide and carbonate.

$$4Na + O_2 \longrightarrow 2Na_2O \xrightarrow{2H_2O} 4NaOH \xrightarrow{2CO_2} In atmosphere$$

$$2Na_2CO_3 + 2H_2O$$

It is always, therefore, kept under kerosene because it corrodes rapidly by reacting with water vapour in the air. On heating in air or oxygen, it forms a mixture of Na<sub>2</sub>O and Na<sub>2</sub>O<sub>2</sub>. Na<sub>2</sub>O<sub>2</sub> is industrially known as **oxone**.

$$\begin{array}{c} 4Na \ + \ O_2 \longrightarrow \ 2Na_2O \\ 4Na \ + \ 2O_2 \longrightarrow \ 2Na_2O_2 \\ \text{Sodium peroxide} \end{array}$$

The peroxide ion,  $O_2^{2-}$  acts as an oxidizing agent.

**(b) Reactivity towards water:** It decomposes water vigorously with evolution of heat and liberating hydrogen. Sometimes the hydrogen catches fire.

$$2Na + 2H_2O \longrightarrow 2NaOH + H_2$$

(c) Reactivity towards acids: It is strongly electropositive in nature, easily loses electron and converted into monovalent ion, Na<sup>+</sup>. On account of this, it readily displaces hydrogen from acids and forms corresponding salts.

$$2Na + 2HCl \longrightarrow 2NaCl + H_2$$

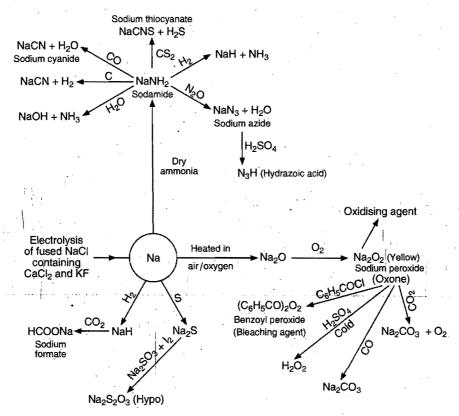

(d) Affinity for non-metals: It has high affinity for non-metals. Except carbon and nitrogen, it directly reacts with hydrogen, halogens, sulphur, phosphorus, etc., to form corresponding compounds on heating.

$$2Na + H_2 \xrightarrow{300^{\circ}C} 2NaH$$

$$2Na + Cl_2 \longrightarrow 2NaCl$$

$$2Na + S \longrightarrow Na_2S$$

$$3Na + P \longrightarrow Na_3P$$

Flowsheet diagram of properties of sodium and preparation of some important compounds

**(e) Reducing agent:** On account of low value of ionisation potential and high value of oxidation potential, it acts as a strong reducing agent.

$$SiO_2 + 4Na \longrightarrow Si + 2Na_2O$$
  
 $3CO_2 + 4Na \longrightarrow C + 2Na_2CO_3$   
 $Al_2O_3 + 6Na \longrightarrow 2Al + 3Na_2O$   
 $BeCl_2 + 2Na \longrightarrow Be + 2NaCl$ 

(f) Reactivity towards ammonia: When dry ammonia is passed over sodium at 300–400°C in absence of air, sodamide is formed with liberation of hydrogen.

$$2Na + 2NH_3 \longrightarrow 2NaNH_2 + H_2$$

Sodamide is a waxy solid and is used for making a number of sodium compounds.

#### Uses

Sodium is used:

- (i) in the manufacture of various chemicals like sodium peroxide (Na<sub>2</sub>O<sub>2</sub>), sodamide (NaNH<sub>2</sub>), sodium cyanide (NaCN), etc.
- (ii) for making lead tetraethyl (used as antiknock in petrol).

$$4C_2H_5Cl + 4Na-Pb \longrightarrow (C_2H_5)_4Pb + 3Pb + 4NaCl$$

(iii) in the preparation of sodium amalgam (used as a reducing agent).

- (iv) in molten state in nuclear reactors as heat transfer medium.
  - (v) in sodium vapour lamps which emit yellow light.
  - (vi) as a laboratory reagent for organic analysis.
- (vii) in high temperature thermometers in the form of sodium potassium alloy.
  - (viii) for the extraction of C, Be, Mg and Si.
- (ix) largely as a reducing agent in industry for the production of artificial rubber, dyes, pharmaceutical drugs, etc.
- (x) for filling exhaust valves of aeroplane engines on account of its lightness and high thermal conductivity.
  - (xi) as a liquid coolant in nuclear power stations.
- (xii) molten sodium metal is used to produce zirconium and titanium from their chloride.

$$TiCl_4(g) + 4Na \xrightarrow{\Delta} 4NaCl(s) + Ti(s)$$

## COMPOUNDS OF SODIUM

#### ■ 1. Sodium Oxide, Na<sub>2</sub>O

**Preparation:** It is prepared by heating sodium nitrate or sodium nitrite with sodium.

$$2NaNO_3 + 10Na \longrightarrow 6Na_2O + N_2$$
  
 $2NaNO_2 + 6Na \longrightarrow 4Na_2O + N_2$ 

Pure sodium oxide is formed when the mixture of sodium azide and sodium nitrite is heated.

$$3NaN_3 + NaNO_2 \longrightarrow 2Na_2O + 5N_2$$

**Properties:** It is a white amorphous substance. It reacts with water violently forming sodium hydroxide and evolving a large amount of heat energy.

$$Na_2O + H_2O \longrightarrow 2NaOH + Heat$$

On heating at 400°C, it disproportionates forming sodium peroxide and metallic sodium vapour.

$$2Na_2O \xrightarrow{400^{\circ}C} Na_2O_2 + 2Na$$

Sodamide is formed when it reacts with liquid ammonia.

$$Na_2O + NH_3 \longrightarrow NaNH_2 + NaOH$$

**Uses:** It is used as dehydrating and polymerising agent in organic chemistry.

#### ■ 2. Sodium Peroxide, Na<sub>2</sub>O<sub>2</sub>

**Preparation:** It is formed by heating sodium in excess of air free from moisture and carbon dioxide or in excess of pure oxygen.

$$2Na + O_2(excess) \xrightarrow{350^{\circ}C} Na_2O_2$$

**Properties:** It is a pale yellow powder. On exposure, it becomes white as it reacts with moisture and carbon dioxide.

$$2Na_2O_2 + 2H_2O \longrightarrow 4NaOH + O_2$$

$$2Na_2O_2 + 2CO_2 \longrightarrow 2Na_2CO_3 + O_2$$

At low temperature, it forms H<sub>2</sub>O<sub>2</sub> with water and acids.

$$Na_2O_2 + 2H_2O \longrightarrow 2NaOH + H_2O_2$$

$$Na_2O_2 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O_2$$

It combines with CO and CO<sub>2</sub>.

$$Na_2O_2 + CO \longrightarrow Na_2CO_3$$

$$2Na_2O_2 + 2CO_2 \longrightarrow 2Na_2CO_3 + O_2$$

It acts as a powerful oxidising agent.

(a) Chromic compounds are oxidised to chromates.

$$[Na_2O_2 + H_2O \longrightarrow 2NaOH + O] \times 3$$

$$2Cr(OH)_3 + 4NaOH + 3O \longrightarrow 2Na_2CrO_4 + 5H_2O$$

$$2Cr(OH)_3 + 3Na_2O_2 \longrightarrow 2Na_2CrO_4 + 2NaOH + 2H_2O$$

(b) Manganous salt is oxidised to sodium manganate.

$$[Na_2O_2 + H_2O \longrightarrow 2NaOH + O] \times 2$$

$$MnSO_4 + 4NaOH + 2O \longrightarrow Na_2MnO_4 + Na_2SO_4 + 2H_2O$$

$$MnSO_4 + 2Na_2O_2 \longrightarrow Na_2MnO_4 + Na_2SO_4$$

(c) Sulphides are oxidised to corresponding sulphates.

$$Na_2S + 4O \longrightarrow Na_2SO_4$$

Benzoyl peroxide (bleaching agent) is formed when  $C_6H_5COCl$  reacts with  $Na_2O_2$ .

$$2C_6H_5COC1 + Na_2O_2 \longrightarrow (C_6H_5CO)_2O_2 + 2NaC1$$
Benzoyl peroxide

**Uses:** It is used:

- (i) as an oxidising agent in laboratory.
- (ii) for the production of oxygen under the name oxone.
- (iii) for the purification of air.
- (iv) as a bleaching agent for delicate fibres like wool, silk, etc.
  - (v) for the preparation of benzoyl peroxide.
  - (vi) for the preparation of  $H_2O_2$ .

#### 3. Sodium Hydroxide (Caustic Soda), NaOH

Sodium hydroxide, NaOH, is a soft, waxy, white, corrosive solid. It is commonly known as lye or caustic soda. It is one of the important chemicals and is manufactured on a very large scale forming an important chemical industry. It is most conveniently manufactured by one of the following processes:

# (a) Methods involving sodium carbonate as a starting material

Two methods are used. These are:

(i) Causticisation process (Gossage process): This process depends on the reaction between suspension of lime (milk of lime, calcium hydroxide) and sodium carbonate. This reaction is reversible.

$$Na_2CO_3 + Ca(OH)_2 \Longrightarrow CaCO_3 + 2NaOH$$

Calcium carbonate being only slightly soluble separates out as a mud. The temperature is maintained 80–90°C by blowing steam. Caustic soda solution is drained out and evaporated to dryness when flakes of caustic soda are obtained.

The most suitable concentration of sodium carbonate taken in this process is 15–20%. The caustic soda produced by this method is not pure and contains some calcium carbonate, sodium carbonate and calcium hydroxide as impurities.

(ii) Lowig's process: In this process, a mixture of sodium carbonate and ferric oxide is heated to redness in a revolving furnace. Sodium ferrite is thus formed with evolution of carbon dioxide.

The sodium ferrite is cooled and thrown into hot water. The hydrolysis of sodium ferrite occurs forming a solution of sodium hydroxide and insoluble ferric oxide (Fe<sub>2</sub>O<sub>3</sub>).

$$2NaFeO_2 + H_2O \longrightarrow 2NaOH + Fe_2O_3$$

The solution is filtered and evaporated to dryness to get flakes of sodium hydroxide.

#### (b) Methods involving sodium chloride as starting material

Methods used are electrolytic as the electrolysis of sodium chloride solution is carried out in an electrolytic cell. **Principle:** A sodium chloride solution contains Na<sup>+</sup>, H<sup>+</sup>, Cl<sup>-</sup> and OH<sup>-</sup> ions.

$$NaCl \rightleftharpoons Na^+ + Cl^-$$
  
 $H_2O \rightleftharpoons H^+ + OH^-$ 

On passing electricity, Na<sup>+</sup> and H<sup>+</sup> ions move towards cathode and Cl<sup>-</sup> and OH<sup>-</sup> ions move towards anode. The discharge potential of H<sup>+</sup> ions is less than Na<sup>+</sup> ions, thus hydrogen ions get discharged easily and hydrogen is liberated. Similarly, at anode Cl<sup>-</sup> ions are easily discharged as their discharge potential is less than that of OH<sup>-</sup> ions. Cl<sub>2</sub> gas is, therefore, liberated at anode.

The solution on electrolysis becomes richer in Na<sup>+</sup> and OH<sup>-</sup> ions.

Since, chlorine reacts with sodium hydroxide solution even in the cold forming sodium chloride and sodium hypochlorite, it is necessary that chlorine should not come in contact with sodium hydroxide during electrolysis.

$$2NaOH + Cl_2 \longrightarrow NaCl + NaClO + H_2O$$

To overcome this problem, the anode is separated from the cathode in the electrolytic cell either by using a porous diaphragm or by using a mercury cathode.

Four methods are used, these are:

- (i) Porous diaphragm process (Nelson cell process)
- (ii) Castner-Kellner cell
- (iii) Solvay-Kellner cell
- (iv) Diaphragm cell
- (i) Porous diaphragm process (Nelson cell process): Nelson cell consists of a perforated steel tube

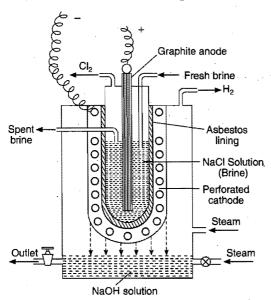

Fig. 6.6 Nelson cell

lined inside with asbestos. The tube acts as a cathode (Fig. 6.6).

It is suspended in a steel tank. A graphite rod dipped in sodium chloride solution serves as anode. On passing electric current,

chlorine is liberated at the anode and let out through the outlet. Sodium ions penetrate through the asbestos and reach the cathode where hydrogen and OH<sup>-</sup> ions are formed by reduction of water. Sodium ions combine with OH<sup>-</sup> ions to form NaOH which is collected in the outer tank while hydrogen is drawn off through the outlet. The steam blown during the process keeps the electrolyte warm and helps to keep perforation clear.

NaCl 
$$\rightleftharpoons$$
 Na<sup>+</sup> + Cl<sup>-</sup> (in solution)  
At cathode:  $2H_2O + 2e \rightleftharpoons H_2 + 2OH^-$   
Na<sup>+</sup> + OH<sup>-</sup>  $\rightleftharpoons$  NaOH  
At anode:  $2Cl^- \longrightarrow Cl_2 + 2e$ 

The solution containing NaOH and NaCl as impurity is taken out and evaporated to dryness.

(ii) Castner-Kellner cell: This is the common cell in which mercury is used as cathode. The advantage of using Hg as a cathode is that the discharge potential of Na<sup>+</sup> ions is less than that of H<sup>+</sup> ions. Na<sup>+</sup> ions get discharged on mercury and sodium so deposited combines with mercury to form sodium amalgam. The cell consists of a large rectangular trough divided into three compartments by slate partitions which do not touch the bottom of the cell but dipping in mercury as shown in the (Fig. 6.7).

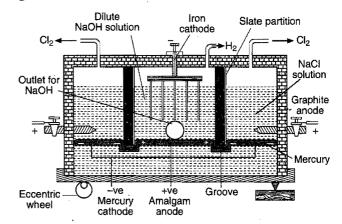

Fig. 6.7 Castner-Kellner cell

The mercury can flow from one compartment into other but the solution kept in one compartment cannot flow into other. Sodium chloride solution is placed in the two outer compartments and a dilute solution of sodium hydroxide in the inner compartment. Two graphite electrodes which act as anodes are fixed in the outer compartments and a series of iron rods fitted in the inner compartment act as cathode. Mercury in the outer compartments acts as cathode while in the inner compartment it acts as anode by induction. The cell is kept rocking with the help of an eccentric wheel.

When electricity is circulated, sodium chloride in the outer compartments is electrolysed. Chlorine is evolved at the graphite anode while Na<sup>+</sup> ions are discharged at the Hg cathode. The liberated sodium forms amalgam with mercury.

NaCl  $\rightleftharpoons$  Na<sup>+</sup> + Cl<sup>-</sup> At anode:  $2Cl^- \longrightarrow 2Cl + 2e \longrightarrow Cl_2$ 

At cathode :  $Na^+ + e \longrightarrow Na$ 

 $Na + Hg \longrightarrow Amalgam$ 

The sodium amalgam thus formed comes in the inner compartment due to rocking. Here, the sodium amalgam acts as the anode and iron rods act as cathode.

At anode: Na-amalgam  $\longrightarrow$  Na<sup>+</sup> + Hg + e At cathode:  $2H_2O + 2e \longrightarrow 2OH^- + H_2\uparrow$ 

The concentrated solution of sodium hydroxide (about 20%) is taken out from inner compartment and evaporated to dryness to get solid NaOH.

(iii) Solvay-Kellner cell: This is the modified cell. This cell has no compartments. The flowing mercury as shown in Fig. 6.8 acts as cathode. A number of graphite rods dipping in sodium chloride solution act as anode. A constant level of sodium chloride solution (brine) is maintained in the cell. On electrolysis chlorine gas is liberated at anode and Na<sup>+</sup> ions are discharged at cathode (mercury). Sodium discharged dissolves in Hg and forms sodium amalgam.

$$2\text{Cl}^- \longrightarrow \text{Cl}_2 + 2\text{l}$$
 (anode reaction)  
 $2\text{Na} + 2\text{Hg} + 2e \longrightarrow 2\text{Na} \cdot \text{Hg}$  (cathode reaction)

This amalgam flows out in a vessel containing water. Sodium hydroxide is formed with evolution of hydrogen.

$$2\text{Na}\cdot\text{Hg} + 2\text{H}_2\text{O} \longrightarrow 2\text{NaOH} + 2\text{Hg} + \text{H}_2\uparrow$$

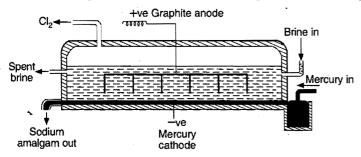

Fig. 6.8 Solvay-Kellner cell

(iv) Diaphragm cell: Most modern method for the production of sodium hydroxide from brine (aqueous sodium

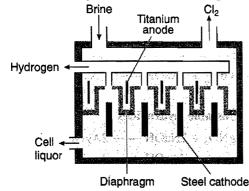

Fig. 6.9 A diaphragm cell for the electrolytic production of sodium hydroxide from brine (aqueous sodium chloride solution)

chloride solution) uses a diaphragm cell, containing steel and titanium electrodes which are separated by porous diaphragms to isolate the products. The process produces chlorine and hydrogen as well as sodium hydroxide.

$$2NaCl + 2H_2O \longrightarrow 2NaOH + Cl_2 + H_2$$

The porous diaphragm prevents the chlorine from mixing with the hydrogen and sodium hydroxide. The liquid is drawn off and the water is partially evaporated. The unconverted sodium chloride crystallizes, leaving the sodium hydroxide in solution.

#### Preparation of pure sodium hydroxide

Commercial sodium hydroxide is purified with the help of alcohol. Sodium hydroxide dissolves in alcohol while impurities like NaCl, Na<sub>2</sub>CO<sub>3</sub>, Na<sub>2</sub>SO<sub>4</sub>, etc., remain insoluble. The alcoholic filtrate is distilled. The alcohol distills off while pure solid sodium hydroxide is left behind.

#### Properties

**Physical Properties:** (a) It is a white crystalline solid. It has soapy touch.

- (b) It is highly deliquescent.
- (c) Its density is 2.13 g/mL and melting point 318.4°C.
- (d) It is highly soluble in water. It is bitter in taste.
- (e) It is corrosive in nature.
- (f) Its solubility is comparatively less in alcohol.

Chemical Properties: (a) Reactivity towards atmosphere: It cannot be kept in atmosphere. It absorbs moisture and carbon dioxide from atmosphere and converted into sodium carbonate.

$$2NaOH + CO_2 \longrightarrow Na_2CO_3 + H_2O$$

**(b) Strong alkali:** Sodium hydroxide is a strong alkali as it dissociates completely in water furnishing Na<sup>+</sup> and OH<sup>-</sup> ions.

$$NaOH \implies Na^+ + OH^-$$

(i) It reacts with acids forming corresponding salts.

$$\begin{array}{c} \text{NaOH} + \text{HCl} & \longrightarrow \text{NaCl} + \text{H}_2\text{O} \\ 2\text{NaOH} + \text{H}_2\text{SO}_4 & \longrightarrow \text{Na}_2\text{SO}_4 + 2\text{H}_2\text{O} \\ \text{NaOH} + \text{HNO}_3 & \longrightarrow \text{NaNO}_3 + \text{H}_2\text{O} \\ 3\text{NaOH} + \text{H}_3\text{PO}_4 & \longrightarrow \text{Na}_3\text{PO}_4 + 3\text{H}_2\text{O} \\ \text{NaOH} + \text{CH}_3\text{COOH} & \longrightarrow \text{CH}_3\text{COONa} + \text{H}_2\text{O} \end{array}$$

(ii) It combines with acidic oxides to form salts.

2NaOH + CO<sub>2</sub> 
$$\longrightarrow$$
 Na<sub>2</sub>CO<sub>3</sub> + H<sub>2</sub>O
Sodium carbonate

2NaOH + SO<sub>2</sub>  $\longrightarrow$  Na<sub>2</sub>SO<sub>3</sub> + H<sub>2</sub>O
Sodium sulphite

2NaOH + 2NO<sub>2</sub>  $\longrightarrow$  NaNO<sub>3</sub> + NaNO<sub>2</sub> + H<sub>2</sub>O
Sodium sodium solitate

(iii) Amphoteric oxides of aluminium, zinc, tin and lead dissolve in sodium hydroxide forming corresponding salts.

$$\begin{array}{c} \text{Al}_2\text{O}_3 + 2\text{NaOH} \longrightarrow & 2\text{NaAlO}_2 + \text{H}_2\text{O} \\ \text{Sodium meta-aluminate} \\ \\ \text{ZnO} + 2\text{NaOH} \longrightarrow & \text{Na}_2\text{ZnO}_2 + \text{H}_2\text{O} \\ \text{Sodium zincate} \\ \\ \text{SnO} + 2\text{NaOH} \longrightarrow & \text{Na}_2\text{SnO}_2 + \text{H}_2\text{O} \\ \text{Sodium stannite} \\ \\ \text{SnO}_2 + 2\text{NaOH} \longrightarrow & \text{Na}_2\text{SnO}_3 + \text{H}_2\text{O} \\ \text{Sodium stannate} \\ \\ \text{PbO} + 2\text{NaOH} \longrightarrow & \text{Na}_2\text{PbO}_2 + \text{H}_2\text{O} \\ \text{Sodium plumbite} \\ \\ \text{PbO}_2 + 2\text{NaOH} \longrightarrow & \text{Na}_2\text{PbO}_3 + \text{H}_2\text{O} \\ \\ \text{Sodium plumbate} \\ \end{array}$$

- (c) Reactivity towards non-metals: Non-metals like halogens, P (yellow), S, Si, B, etc., are attacked by NaOH.
- (i) Halogens: Hypohalites and halides are formed by reaction of halogens with cold and dilute solution of NaOH.

$$\begin{array}{c} \text{Cl}_2 + 2\text{NaOH} & \longrightarrow \text{NaCl} + & \text{NaClO} & + \text{H}_2\text{O} \\ \text{(cold and dilute)} & & \text{Sodium hypo-chlorite} \\ \\ \text{Br}_2 + 2\text{NaOH} & \longrightarrow \text{NaBr} + & \text{NaBrO} & + \text{H}_2\text{O} \\ \text{(cold and dilute)} & & \text{Sodium hypo-bromite} \\ \\ \text{I}_2 + 2\text{NaOH} & \longrightarrow \text{NaI} + & \text{NaIO} & + \text{H}_2\text{O} \\ \text{(cold and dilute)} & & \text{Sodium hypo-iodite} \\ \end{array}$$

Halogens form halates and halides with hot and concentrated solution of NaOH.

$$3\text{Cl}_2 + 6\text{NaOH} \longrightarrow 5\text{NaCl} + \text{NaClO}_3 + 3\text{H}_2\text{O}$$
(hot and conc.)

 $3\text{Br}_2 + 6\text{NaOH} \longrightarrow 5\text{NaBr} + \text{NaBrO}_3 + 3\text{H}_2\text{O}$ 
(hot and conc.)

 $3\text{I}_2 + 6\text{NaOH} \longrightarrow 5\text{NaI} + \text{NaIO}_3 + 3\text{H}_2\text{O}$ 
(hot and conc.)

 $3\text{Sodium bromate}$ 
 $3\text{Sodium iodate}$ 

(ii) Yellow phosphorus (white) when heated with NaOH solution evolves phosphine gas (PH<sub>3</sub>) along with the formation of sodium hypophosphite.

P<sub>4</sub> + 3NaOH + 3H<sub>2</sub>O 
$$\longrightarrow$$
 3NaH<sub>2</sub>PO<sub>2</sub> + PH<sub>3</sub> Sodium Phosphine hypophosphite

(iii) Sulphur on heating with sodium hydroxide solution forms sodium thiosulphate.

$$\begin{array}{c} \text{4S + 6NaOH} \longrightarrow \text{Na}_2\text{S}_2\text{O}_3 + 2\text{Na}_2\text{S} + 3\text{H}_2\text{O} \\ \text{Sodium thio-} \\ \text{sulphate} & \text{sulphide} \end{array}$$

(iv) Silicon evolves hydrogen when heated with NaOH solution.

$$2NaOH + Si + H_2O \longrightarrow Na_2SiO_3 + 2H_2$$
  
Sodium silicate

(v) Boron also evolves hydrogen when fused with NaOH.

$$\begin{array}{ccc} 2B + 6NaOH & \longrightarrow & 2Na_3BO_3 & + & 3H_2 \\ & & \text{Sodium borate} \end{array}$$

(d) Reactivity towards metals: Metals like Zn, Al, Sn, Pb react with sodium hydroxide solution and evolve hydrogen.

$$Zn + 2NaOH \longrightarrow Na_2ZnO_2 + H_2$$
  
 $2Al + 2NaOH + 2H_2O \longrightarrow 2NaAlO_2 + 3H_2$   
 $Sn + 2NaOH + H_2O \longrightarrow Na_2SnO_3 + 2H_2$   
 $Pb + 2NaOH + H_2O \longrightarrow Na_2PbO_3 + 2H_2$ 

[However, Sn and Pb when fused with NaOH form Na<sub>2</sub>SnO<sub>2</sub> and Na<sub>2</sub>PbO<sub>2</sub>, respectively.

$$Sn + 2NaOH \longrightarrow Na_2SnO_2 + H_2$$
  
 $Pb + 2NaOH \longrightarrow Na_2PbO_2 + H_2$ 

- (e) Action on salts: Sodium hydroxide reacts with metallic salts to form hydroxides which may be insoluble or dissolve in excess of NaOH to form salts of oxyacids. Some of the hydroxides decompose into insoluble oxides.
- (i) Insoluble hydroxides: Salts of nickel, iron, manganese, copper, etc., form insoluble hydroxides.

$$\begin{array}{c} \text{Ni}(\text{NO}_3)_2 \,+\, 2\text{NaOH} \longrightarrow \text{Ni}(\text{OH})_2 \,+\, 2\text{NaNO}_3 \\ \\ \text{FeSO}_4 \,+\, 2\text{NaOH} \longrightarrow \text{Fe}(\text{OH})_2 \,+\, \text{Na}_2\text{SO}_4 \\ \\ \text{FeCl}_3 \,+\, 3\text{NaOH} \longrightarrow \text{Fe}(\text{OH})_3 \,+\, 3\text{NaCl} \\ \\ \text{Red ppt}, \\ \\ \text{CrCl}_3 \,+\, 3\text{NaOH} \longrightarrow \text{Cr}(\text{OH})_3 \,+\, 3\text{NaCl} \\ \\ \text{Green ppt}, \\ \\ \text{MnSO}_4 \,+\, 2\text{NaOH} \longrightarrow & \text{Mn}(\text{OH})_2 \,+\, \text{Na}_2\text{SO}_4 \\ \\ \text{Buff coloured ppt}, \\ \\ \text{CuSO}_4 \,+\, 2\text{NaOH} \longrightarrow & \text{Cu}(\text{OH})_2 \,+\, \text{Na}_2\text{SO}_4 \\ \\ \text{Blue coloured ppt}, \\ \end{array}$$

(ii) Insoluble hydroxides which dissolve in excess of NaOH:

$$ZnSO_4 + 2NaOH \longrightarrow Zn(OH)_2 + Na_2SO_4$$
White (insoluble)
$$Zn(OH)_2 + 2NaOH \longrightarrow Na_2ZnO_2 + 2H_2O$$
Sodium zincate
(soluble)
$$AlCl_3 + 3NaOH \longrightarrow Al(OH)_3 + 3NaCl$$
White ppt.
$$Al(OH)_3 + NaOH \longrightarrow NaAlO_2 + 2H_2O$$
Sodium meta-
aluminate (soluble)
$$SnCl_2 + 2NaOH \longrightarrow Sn(OH)_2 + 2NaCl$$
White ppt.
$$Sn(OH)_2 + 2NaOH \longrightarrow Na_2SnO_2 + 2H_2O$$
Sodium stannite
(soluble)

(iii) Unstable hydroxides:

$$2 Ag NO_3 + 2 NaOH \longrightarrow 2 Ag OH + 2 NaNO_3$$

$$2 Ag OH \longrightarrow Ag_2O + H_2O$$

$$(Brown)$$

$$Hg Cl_2 + 2 NaOH \longrightarrow Hg (OH)_2 + 2 NaCl$$

$$Hg (OH)_2 \longrightarrow HgO + H_2O$$

$$(Yellow)$$

**(f) Reactivity towards ammonium salts:** Ammonium salts are decomposed on heating with sodium hydroxide solution with the evolution of ammonia gas.

$$NH_4Cl + NaOH \longrightarrow NH_3 \uparrow + NaCl + H_2O$$
  
 $(NH_4)_2SO_4 + 2NaOH \longrightarrow Na_2SO_4 + 2NH_3 \uparrow + 2H_2O$ 

**(g) Reactivity towards carbon monoxide:** NaOH reacts with carbon monoxide under pressure at 150–200°C to form sodium formate.

NaOH + CO 
$$\xrightarrow{5-10}$$
 atm. HCOONa Sodium formate

(h) Caustic property: Sodium hydroxide breaks down the proteins of skin to a pasty mass. On account of this property, it is commonly called as Caustic soda.

#### **■** Uses

Sodium hydroxide is among the top ten industrial chemicals. It is an important industrial chemical because it is an inexpensive base for the production of other sodium salts. It is a strong base, and this property is useful in many applications. It is used:

- (i) as a reagent in the laboratory.
- (ii) in refining of petroleum.
- (iii) in the manufacture of soap.
- (iv) in the manufacture of sodium metal.
- (v) in the manufacture of paper and rayon.
- (vi) in the manufacture of dyes and drugs.
- (vii) as an absorber of gases.
- (viii) in the manufacture of sodium hypochlorite, sodium chlorate and sodium nitrite.
  - (ix) for mercerizing cotton.
- (x) In large quantities in the production of aluminium which depends on its reaction with the amphoteric aluminium hydroxide.

#### 4. Sodium Carbonate or Washing Soda (Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O)

Sodium carbonate ( $Na_2CO_3$ ) is the most important of all alkali salts in commercial use. It is one of the world's most important industrial chemicals. It occurs in the ashes of marine plants which used to be its only source upto 1790. It is also found as natural deposits like sajji in India and trona ( $Na_2CO_3\cdot NaHCO_3\cdot 2H_2O$ ) in Egypt. The world production of sodium carbonate now exceeds 30 million tonnes per year.

#### **Manufacture**

The first process for the manufacture of  $Na_2CO_3$  was invented by Le-Blanc in 1790. However, this process has become obsolete and has been replaced by modern methods. The most important one is Solvay process. The following are the three main processes for the manufacture of sodium carbonate:

- (a) Le-Blanc process,
- (b) Solvay ammonia soda process and
- (c) Electrolytic process.

#### (a) Le-Blanc process

The raw materials of this process are common salt (NaCl), sulphuric acid, coke and limestone (CaCO<sub>3</sub>). It involves the following steps:

(i) Conversion of NaCl into Na<sub>2</sub>SO<sub>4</sub>: The common salt is heated with calculated quantity of sulphuric acid (concentrated) in the furnace shown in Fig. 6.10.

$$NaCl + H_2SO_4 \longrightarrow NaHSO_4 + HCl$$
Sodium hydrogen
sulphate

The pasty mass of NaHSO<sub>4</sub> is then raked out on the hearth of the furnace with common salt. The paste is heated at higher

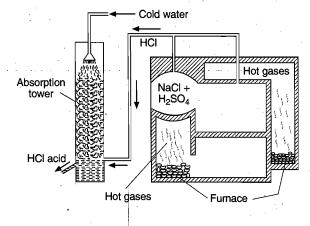

Fig. 6.10 Le-Blanc process

temperature when sodium hydrogen sulphate is converted into sodium sulphate.

$$NaHSO_4 + NaCl \longrightarrow Na_2SO_4 + HCl$$

Sodium sulphate, thus formed is technically called **salt cake**. The HCl evolved is dissolved in water to form hydrochloric acid.

(ii) Conversion of salt cake into black ash: The salt cake formed in the first step is broken into small pieces. These pieces are mixed with coke and limestone. The mixture is introduced into the cylindrical revolving furnace where it is strongly heated. Sodium sulphate is converted into sodium carbonate along with calcium sulphide with evolution of carbon monoxide according to the following reaction.

$$Na_2SO_4 + CaCO_3 + 4C \longrightarrow \underbrace{Na_2CO_3 + CaS}_{Black\ ash} + 4CO$$

The solid residue is called **black ash.** This contains about 45% sodium carbonate.

(iii) Recovery of Na<sub>2</sub>CO<sub>3</sub>: The black ash is crushed and extracted with water. The sodium carbonate dissolves and the insoluble impurities mainly consisting CaS are left behind. The insoluble material is called sludge or alkali waste. The solution consisting sodium carbonate is evaporated to get solid sodium carbonate.

## (b) Solvay ammonia soda process

This is the modern process used for the manufacture of sodium carbonate worldwide, a large quantity of sodium carbonate is still produced by the **solvay process**. It is an industrial method for obtaining sodium carbonate from sodium chloride and limestone (CaCO<sub>3</sub>). The raw materials required in this process are the common salt, ammonia and limestone. In the main steps of this process, ammonia is 1st dissolved in a saturated solution of sodium chloride and then carbon dioxide is passed in it. The process involves the formation of a sparingly soluble sodium bicarbonate (baking soda) by the reaction of sodium chloride and ammonium bicarbonate in aqueous solution. The reactions taking place in the process are:

NH<sub>3</sub> + H<sub>2</sub>O + CO<sub>2</sub> 
$$\longrightarrow$$
 NH<sub>4</sub>HCO<sub>3</sub>
Ammonium
bicarbonate

NaCl + NH<sub>4</sub>HCO<sub>3</sub>  $\longrightarrow$  NaHCO<sub>3</sub> + NH<sub>4</sub>Cl
Sodium
bicarbonate

$$NH_3 + H_2O + CO_2 + NaCl \longrightarrow NaHCO_3 + NH_4Cl$$

Sodium bicarbonate on heating decomposes into sodium carbonate.

$$2NaHCO_3 \xrightarrow{\Delta} Na_2CO_3 + H_2O + CO_2$$

The various steps involved in the process are:

(i) Saturation of brine with ammonia: This step is done in ammonia absorber (Fig. 6.11). Ammonia from the ammonia generator is circulated through the solution. The ammonical brine solution is allowed to stand for some time as to allow any precipitate formed to settle down. Ammonia precipitates, the hydroxides of magnesium, iron, calcium, etc., if present as impurity in the common salt.

$$NH_3 + H_2O \longrightarrow NH_4OH$$
 $MgCl_2 + 2NH_4OH \longrightarrow Mg(OH)_2 + 2NH_4Cl_{ppt}$ 

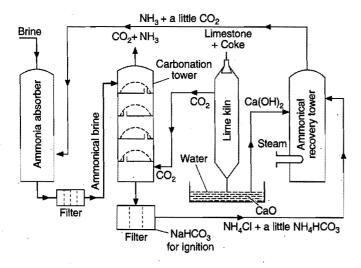

Fig. 6.11 Solvay ammonia soda process

Ammonia mixed with a little carbon dioxide if used, precipitates calcium and magnesium as carbonates.

$$CaCl_2 + 2NH_3 + H_2O + CO_2 \longrightarrow CaCO_3 + 2NH_4Cl_{ppt}$$

The clear liquid is now allowed to go into the carbonation tower.

(ii) Carbonation: Ammonical brine solution is cooled in the cooling pipe and then allowed to enter a little above the middle of the carbonation tower packed with perforated plates. It flows down slowly in the tower and meets with an upward stream of carbon dioxide. The sparingly soluble sodium bicarbonate (NaHCO<sub>3</sub>) gets precipitated. This is taken out from the tower.

$$NaCl + NH_3 + H_2O + CO_2 = NaHCO_3 + NH_4Cl$$

- (iii) Filtration: The solution obtained from carbonation tower is filtered with the help of rotatory vacuum filter. The filtrate is pumped to the top of recovery tower.
- (iv) Ammonia recovery: The filtrate from the vacuum filter contains ammonium chloride and a little ammonium bicarbonate. Ammonia is recovered from this filtrate by passing steam and adding Ca(OH)<sub>2</sub>. This ammonia is again used.

$$\begin{array}{c} \text{NH}_4\text{HCO}_3 \xrightarrow{\text{Heat}} \text{NH}_3 + \text{H}_2\text{O} + \text{CO}_2 \\ 2\text{NH}_4\text{Cl} + \text{Ca}(\text{OH})_2 &\longrightarrow 2\text{NH}_3 + \text{CaCl}_2 + 2\text{H}_2\text{O} \end{array}$$

(v) Calcination: Sodium bicarbonate obtained in step (ii) is strongly heated in especially designed cylindrical vessels when sodium carbonate is obtained.

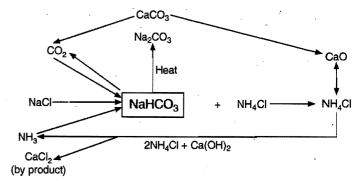

$$2\text{NaHCO}_3 \xrightarrow{250^{\circ}\text{C}} \text{Na}_2\text{CO}_3 + \text{H}_2\text{O} + \text{CO}_2$$

Carbon dioxide used in the carbonating tower is produced by heating limestone, CaCO<sub>3</sub>.

$$CaCO_3 \longrightarrow CaO + CO_2$$
Calcium oxide

The calcium oxide (CaO) produced from this process is known as quicklime or lime. It is dissolved in water to form calcium hydroxide which is used for the recovery of ammonia.

The byproduct of this process is calcium chloride. The process on the whole is cheap, self-contained and self-sufficient and the product formed, Na<sub>2</sub>CO<sub>3</sub>, is of high purity.

Flow Sheet of Solvay Process

## (c) Electrolytic process

In this process sodium chloride is first converted into sodium hydroxide by electrolysis. In the Nelson cell used for the manufacture of sodium hydroxide, carbon dioxide under pressure is blown along with steam. The sodium hydroxide produced will then react with carbon dioxide to form sodium carbonate. The solution is concentrated and crystallised.

$$2NaOH + CO_2 \longrightarrow Na_2CO_3 + H_2O$$

Sodium carbonate can also be made in the laboratory by neutralising sodium hydroxide solution with carbon dioxide. The solution on concentration and cooling deposits crystals of the decahydrate;  $Na_2CO_3 \cdot 10H_2O$ .

## Properties

**Physical Properties:** (a) Sodium carbonate is a white crystalline solid. It is known in several hydrated forms. The common form is decahydrate, Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O. This form is called **washing soda.** The decahydrate form on standing in air effloresces and crumbles to powder. It is the monohydrate form, Na<sub>2</sub>CO<sub>3</sub>·H<sub>2</sub>O. It also forms a heptahydrate, Na<sub>2</sub>CO<sub>3</sub>·7H<sub>2</sub>O.

(b) On heating, the monohydrate changes into the anhydrous form which does not decompose on further heating even to redness. It is the amorphous powder and called **soda ash.** It melts at 852°C.

$$\begin{aligned} \text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O} & \xrightarrow{\text{below } 373\,\text{K}} \text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O} + 9\text{H}_2\text{O} \\ \text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O} & \xrightarrow{\text{above } 373\,\text{K}} \text{Na}_2\text{CO}_3 + \text{H}_2\text{O} \\ & \text{Soda ash} \end{aligned}$$

(c) It is soluble in water with evolution of considerable amount of heat. The solution is alkaline in nature due to hydrolysis.

$$Na_2CO_3 + 2H_2O \rightleftharpoons 2NaOH + H_2CO_3$$

When the hot solution of sodium carbonate is concentrated and cooled, crystals of decahydrate form are obtained.

Chemical Properties: (a) Reaction with acids: It is readily decomposed by acids with evolution of carbon dioxide. The reaction occurs in two steps.

$$Na_2CO_3 + HCl \longrightarrow NaHCO_3 + NaCl$$
  
 $NaHCO_3 + HCl \longrightarrow NaCl + H_2O + CO_2$ 

(b) Reaction with CO<sub>2</sub>: On passing CO<sub>2</sub> through the concentrated solution of sodium carbonate, sodium bicarbonate gets precipitated.

$$Na_2CO_3 + H_2O + CO_2 \longrightarrow 2NaHCO_3$$

(c) Reaction with silica: When the mixture of sodium carbonate and silica is fused, sodium silicate is formed.

$$Na_2CO_3 + SiO_2 \longrightarrow Na_2SiO_3 + CO_2 \uparrow$$

Sodium silicate is called **soluble glass** or **water glass** as it is soluble in water.

(d) Reaction with slaked lime: Sodium hydroxide is formed when the solution of sodium carbonate and slaked lime, Ca(OH)<sub>2</sub>, is heated.

$$Na_2CO_3 + Ca(OH)_2 \longrightarrow 2NaOH + CaCO_3$$

(e) Reaction with sulphur and sulphur dioxide: When aqueous solution of sodium carbonate containing sulphur is treated with sulphur dioxide, sodium thiosulphate (Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>) is formed.

$$Na_2CO_3 + SO_2 \xrightarrow{H_2O} Na_2SO_3 + CO_2 \uparrow$$
  
 $Na_2SO_3 + S \longrightarrow Na_2SO_3$ 

(f) Action on salts of non-alkali metals: Sodium carbonate reacts with metal salts (except alkali metal salts) to form insoluble normal or basic carbonates.

$$\begin{aligned} \text{CaCl}_2 + \text{Na}_2\text{CO}_3 &\longrightarrow \text{CaCO}_3 + 2\text{NaCl} \\ \text{BaCl}_2 + \text{Na}_2\text{CO}_3 &\longrightarrow \text{BaCO}_3 + 2\text{NaCl} \\ 2\text{MgCl}_2 + 2\text{Na}_2\text{CO}_3 + \text{H}_2\text{O} &\longrightarrow \text{MgCO}_3 \cdot \text{Mg(OH)}_2 + 4\text{NaCl} \\ & \text{Basic magnesium} &+ \text{CO}_2 \end{aligned}$$

$$5ZnSO_4 + 5Na_2CO_3 + 4H_2O \longrightarrow$$

$$[2ZnCO_3 \cdot 3Zn(OH)_2] \cdot H_2O + 5Na_2SO_4 + 3CO_2$$
Basic zinc carbonate

$$CuSO_4 + Na_2CO_3 \longrightarrow CuCO_3 + Na_2SO_4$$

$$2CuSO_4 + 2Na_2CO_3 + H_2O \longrightarrow Cu(OH)_2 \cdot CuCO_3 + CO_2 + Na_2SO_4$$
Basic copper carbonate

$$3(CH_3COO)_2Pb + 3Na_2CO_3 + H_2O \longrightarrow \\ 2PbCO_3Pb(OH)_2 + CO_2 + 6CH_3COONa \\ Basic lead carbonate \\ .$$

$$2AgNO_3 + Na_2CO_3 \longrightarrow Ag_2CO_3 + 2NaNO_3$$

Carbonates of metals like Fe, Al, Sn, etc., when formed are immediately hydrolysed to hydroxides.

$$Fe_2(SO_4)_3 + 3Na_2CO_3 \longrightarrow Fe_2(CO_3)_3 + 3Na_2SO_4$$
$$Fe_2(CO_3)_3 + 3H_2O \longrightarrow 2Fe(OH)_3 + 3CO_2$$

## ■ Uses

Sodium carbonate is used:

- (i) in the manufacture of soaps, detergents, dyes, drugs and other chemicals.
  - (ii) in laundries and in softening of water as washing soda.
- (iii) in the manufacture of glass, sodium silicate, paper, borax, soap powders, caustic soda, etc.
- (iv) as a laboratory reagent. The mixture of  $Na_2CO_3$  and  $K_2CO_3$  is used as a fusion mixture. It is used in quantitative analysis to standardise acid solutions. In qualitative analysis, it is used in the detection of acidic radicals especially of insoluble salts.
  - (v) in textile, petroleum refining, paints and dyes.
  - (vi) for the preparation of various carbonates of metals.

## 5. Sodium bicarbonate (Baking soda), NaHCO<sub>3</sub>

**Preparation:** Sodium hydrogen carbonate, NaHCO<sub>3</sub> (Sodium bicarbonate), is commonly called **bicarbonate of soda** or **baking soda**. It is obtained as the intermediate product in the solvay ammonia soda process. Normal carbonate can be changed to bicarbonate by passing carbon dioxide through its saturated solution.

$$Na_2CO_3 + CO_2 + H_2O \longrightarrow 2NaHCO_3$$
Sparingly soluble

**Properties:** It is a white crystalline solid, sparingly soluble in water. The solution is alkaline in nature due to hydrolysis. The solution is weakly basic.

$$NaHCO_3 + H_2O \implies NaOH + H_2CO_3$$

The solution gives yellow colour with methyl orange but no colour with phenolphthalein.

On heating, it loses carbon dioxide and water forming sodium carbonate.

$$2NaHCO_3 \longrightarrow Na_2CO_3 + H_2O + CO_2$$

The metal salt which forms basic carbonate with sodium carbonate, gives normal carbonate with sodium bicarbonate.

$$ZnSO_4 + 2NaHCO_3 \longrightarrow ZnCO_3 + Na_2SO_4 + H_2O + CO_2$$

## Uses

- (i) It is used as a medicine (sodabicarb) to neutralise the acidity in the stomach.
- (ii) It is largely used for making baking powder. Baking powder is a mixture of potassium hydrogen tartrate and sodium bicarbonate. Baking powder is also prepared by using NaHCO<sub>3</sub> (30%), starch (40%), calcium hydrogen phosphate (10%) and NaAl(SO<sub>4</sub>)<sub>2</sub>.
  - (iii) It is used in making effervescent drinks.
  - (iv) It is used in fire extinguishers.
  - (v) It is used for production of carbon dioxide.

## 6. Sodium Thiosulphate, (Hypo), Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O

It is the sodium salt of an unstable acid, thiosulphuric acid  $(H_2S_2O_3)$ . It is also known as **hypo.** The following methods can be used for its preparation.

(i) It is obtained by boiling sodium sulphite solution with flowers of sulphur.

$$\begin{array}{cccc} Na_2SO_3 & + & S & \longrightarrow & Na_2S_2O_3 \\ Sodium & Sulphur & Sodium \\ sulphite & & thiosulphate \end{array}$$

The unreacted sulphur is filtered off and the filtrate is evaporated to crystallisation.

(ii) Spring's reaction: The mixture of sodium sulphite and sodium sulphide is treated with calculated quantity of iodine.

$$Na_2S + I_2 + Na_2SO_3 \longrightarrow Na_2S_2O_3 + 2NaI$$

The resulting solution is concentrated and allowed to crystallise when crystals of sodium thiosulphate being less soluble separate out first.

(iii) When the solution containing sodium carbonate and sodium sulphide is treated with sulphur dioxide, sodium thiosulphate is formed with evolution of carbon dioxide.

$$2Na_2S + Na_2CO_3 + 4SO_2 \longrightarrow 3Na_2S_2O_3 + CO_2 \uparrow$$

(iv) Sodium thiosulphate is formed when sulphur is heated with caustic soda solution.

$$4S + 6NaOH \longrightarrow Na_2S_2O_3 + 2Na_2S + 3H_2O$$

With excess of sulphur, sodium pentasulphide is formed,

$$Na_2S + 4S \longrightarrow Na_2S_5$$

(v) On passing SO<sub>2</sub> gas through the solution of Na<sub>2</sub>CO<sub>3</sub> in presence of sulphur we get sodium thiosulphate.

$$Na_2CO_3 + SO_2 \longrightarrow Na_2SO_3 + CO_2$$
  
 $Na_2SO_3 + S \longrightarrow Na_2S_2O_3$ 

## **Properties**

- (i) It is a colourless crystalline solid consisting of 5 molecules of water as water of crystallisation. It has the formula, Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O. It is soluble in water. It melts at 48°C.
- (ii) Action of heat: It is efflorescent substance. The water molecules are completely lost when heated at 215°C.

$$Na_2S_2O_3 \cdot 5H_2O \xrightarrow{215^{\circ}C} Na_2S_2O_3 + 5H_2O$$

When strongly heated above 223°C, it decomposes forming sodium sulphate (salt cake) and sodium pentasulphide.

$$4Na_2S_2O_3 \longrightarrow 3Na_2SO_4 + Na_2S_5$$

(iii) Reaction with acids: Dilute acids decompose it with evolution of SO<sub>2</sub> and precipitation of sulphur.

$$Na_2S_2O_3 + 2HCl \longrightarrow 2NaCl + SO_2 + S + H_2O$$
  
 $Na_2S_2O_3 + H_2SO_4 \longrightarrow Na_2SO_4 + SO_2 + S + H_2O$ 

(iv) Oxidation: It is oxidised by iodine quantitatively.

$$2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6$$
Sodium
tetrathionate

In this reaction, colour of iodine disappears.

(v) Reducing action: It is oxidised by chlorine and bromine water. Sulphur is precipitated.

$$Na_2S_2O_3 + Cl_2 + H_2O \longrightarrow Na_2SO_4 + 2HCl + S$$
  
It reduces FeCl<sub>3</sub> to FeCl<sub>2</sub>

$$2Na_2S_2O_3 + 2FeCl_3 \longrightarrow Na_2S_4O_6 + 2FeCl_2 + 2NaCl$$

(vi) Reaction with AgNO<sub>3</sub>: A white precipitate of silver thiosulphate is obtained which changes to yellow, brown and finally black due to the formation of silver sulphide.

$$2AgNO_3 + Na_2S_2O_3 \longrightarrow Ag_2S_2O_3 + 2NaNO_3$$
  
 $Ag_2S_2O_3 + H_2O \longrightarrow Ag_2S + H_2SO_4$ 

(vii) Reaction with silver halides: Halides form complexes with sodium thiosulphate. Silver bromide forms argentothiosulphate complex.

Similar reactions are observed with AgCl and AgI.

This property is utilised in photography for fixing the negative and positive of black and white photography. It removes undecomposed AgBr present on the film.

(viii) Reaction with copper sulphate: Cuprous thiosulphate is formed which dissolves in excess of sodium thiosulphate to form a complex.

$$\begin{array}{c} \text{CuSO}_4 \,+\, \text{Na}_2\text{S}_2\text{O}_3 &\longrightarrow \text{CuS}_2\text{O}_3 \,+\, \text{Na}_2\text{SO}_4 \\ & \text{Cupric} \\ \text{thiosulphate} \\ \\ 2\text{CuS}_2\text{O}_3 \,+\, \text{Na}_2\text{S}_2\text{O}_3 &\longrightarrow \text{Cu}_2\text{S}_2\text{O}_3 \,+\, \text{Na}_2\text{S}_4\text{O}_6 \\ & \text{Cuprous} \\ \text{thiosulphate} \\ \\ 3\text{Cu}_2\text{S}_2\text{O}_3 \,+\, 2\text{Na}_2\text{S}_2\text{O}_3 &\longrightarrow \begin{array}{c} \text{Na}_4[\text{Cu}_6(\text{S}_2\text{O}_3)_5] \\ \text{Sodium} & \text{cuprothiosulphate} \end{array}$$

## Uses

Sodium thiosulphate is used:

- (i) as an antichlor to remove excess of chlorine from bleached fabrics.
  - (ii) in the extraction of silver and gold.
  - (iii) in photography as a fixing agent in the name of hypo.
- (iv) as a reagent in iodometric and iodimetric titrations for the estimation of iodine, CuSO<sub>4</sub>, K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, KMnO<sub>4</sub>, Na<sub>3</sub>AsO<sub>3</sub>, etc.

## **■ 7. Microcosmic Salt, Na(NH<sub>4</sub>)HPO<sub>4</sub>·4H<sub>2</sub>O**

**Preparation:** It is prepared by dissolving ammonium chloride and disodium hydrogen phosphate in molecular proportion in hot water.

$$NH_4Cl + Na_2HPO_4 + 4H_2O \longrightarrow NaNH_4HPO_4 \cdot 4H_2O + NaCl$$

The sparingly soluble microcosmic salt separates out. It is filtered and purified by recrystallisation.

## **Properties**

- (i) It is colourless crystalline solid, sparingly soluble in water.
- (ii) When heated, it melts to form a clear transparent mass which has the property of combining with metallic oxides to form coloured orthophosphates.

$$Na(NH_4)HPO_4 \longrightarrow NaPO_3 + NH_3 + H_2O$$
Sodium
metaphosphate

 $NaPO_3 + CuO \longrightarrow NaCuPO_4$ 
Blue mass

On account of this property, microcosmic salt is used for the detection of coloured ions. The test is similar to borax bead test. The salt is heated on a loop of a platinum wire, a transparent bead is formed. When hot bead is brought in contact with coloured substance and strongly heated, a coloured bead is formed if the substance contains Cu<sup>2+</sup>, Ni<sup>2+</sup>, Mn<sup>2+</sup>, Co<sup>2+</sup>, etc.

Uses: It is especially used for testing silica with which a cloudy bead containing floating properties of silica is obtained.

## **8.** Sodium Chloride (Common Salt), NaCl

Sodium chloride is the most common of the salts of sodium. It is also called common salt, table salt, rock salt or sea salt. An aqueous solution of sodium chloride is known as **brine**. Sea water contains about 2.95 per cent sodium chloride. As a rock salt it is found at several places in England, Australia, Germany, Canada, Pakistan (Khewra—Punjab) and India (Mandi—Himachal Pradesh). It is found in land lakes (e.g., Sambhar lake in India, lake Elton in Russia).

## Manufacture from sea water

In tropical countries like India, on the sea coasts, the sea water is allowed to dry up under summer heat in small tanks or pits. The solid crust so formed is collected.

In very cold countries, the sea water is concentrated by freezing. The concentrated solution is then evaporated in big iron pans. Sodium chloride thus obtained contains impurities like magnesium chloride, calcium chloride, etc. It is purified by passing hydrogen chloride through a saturated solution of the commercial salt. The precipitation of sodium chloride occurs due to common ion effect.

## **Properties**

- (a) It is a white crystalline solid. It is slightly hygroscopic.
- (b) Its density is 2.17 g/mL when pure. It melts at 800°C. It is soluble in water. It dissolves in water with absorption of heat.
  - (c) It is insoluble in alcohol.
- (d) The common salt is the starting material for the preparation of all the other sodium compounds and extraction of sodium. Sodium, sodium hydroxide and sodium carbonate are the three main materials obtained from common salt which are then used to prepare other important compounds of sodium.

## **Uses**

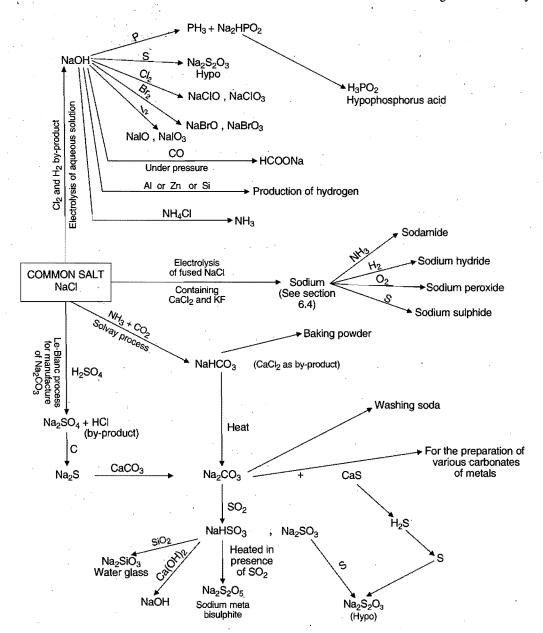

- (i) It is an essential constituent of food.
- (ii) It is used as a preservative of food articles like fish, meat, etc.
  - (iii) It is used for making useful sodium compounds.
- (iv) It finds application in salting out of soap, and in making freezing mixtures.
  - (v) Impure salt (rock salt) is used to de-ice roads.

## 9. Sodium Cyanide, NaCN

It is manufactured by the following methods:

(i) **From sodium:** Sodamide is first formed by passing dry ammonia gas over heated sodium in iron retorts at 300-400°C.

$$2Na + 2NH_3 \longrightarrow 2NaNH_2 + H_2 \uparrow$$

Flowsheet chart for the properties of sodium chloride and preparation of various compounds of sodium

The molten sodamide thus obtained is dropped on red hot charcoal when first sodium cyanamide and then sodium cyanide is formed.

$$2NaNH_2 + C \longrightarrow Na_2CN_2 + 2H_2$$

$$Na_2CN_2 + C \longrightarrow 2NaCN$$

$$2NaNH_2 + 2C \longrightarrow 2NaCN + 2H_2$$
or
$$NaNH_2 + C \longrightarrow NaCN + H_2$$

(ii) From calcium cyanamide: NaCN is prepared by fusing a mixture of crude calcium cyanamide (nitrolim) and sodium carbonate in the presence of carbon.

$$CaCN_2 + C + Na_2CO_3 \longrightarrow 2NaCN + CaCO_3$$

The fused product is extracted with water and the solution on evaporation gives NaCN.

(iii) From gas works: Coal gas is always contaminated with some hydrocyanic acid and ammonia. Before it is put into use, it is passed through copper sulphate solution when ammonium tricyanocuprate (I) is formed.

$$2\text{CuSO}_4 + 4\text{HCN} \longrightarrow 2\text{CuCN} + (\text{CN})_2 + 2\text{H}_2\text{SO}_4$$
  
 $N\text{H}_3 + \text{HCN} \longrightarrow N\text{H}_4\text{CN}$   
 $2N\text{H}_4\text{CN} + \text{CuCN} \longrightarrow (N\text{H}_4)_2[\text{Cu(CN})_3]$ 

The complex is decomposed by the addition of dilute H<sub>2</sub>SO<sub>4</sub> and the evolved HCN is absorbed in caustic soda.

$$\begin{aligned} (NH_4)_2[Cu(CN)_3] + H_2SO_4 & \longrightarrow (NH_4)_2SO_4 + CuCN + 2HCN \\ NaOH + HCN & \longrightarrow NaCN + H_2O \end{aligned}$$

## **Properties**

It is a white crystalline solid. It has a characteristic smell and highly poisonous in nature. It is soluble in water and its solution is alkaline due to hydrolysis.

It forms complex cyanides with the salts of copper, silver, gold, cadmium, zinc, iron, cobalt, nickel, etc. Some examples are given below:

(i) 
$$AgNO_3 + NaCN \longrightarrow AgCN + NaNO_3$$
  
 $AgCN + NaCN \longrightarrow Na[Ag(CN)_2]$ 

(ii) 
$$CdSO_4 + 2NaCN \longrightarrow Cd(CN)_2 + Na_2SO_4$$
  
 $Cd(CN)_2 + 2NaCN \longrightarrow Na_2[Cd(CN)_4]$ 

(iii) FeSO<sub>4</sub> + 2NaCN 
$$\longrightarrow$$
 Na<sub>2</sub>SO<sub>4</sub> + Fe(CN)<sub>2</sub>  
Fe(CN)<sub>2</sub> + 4NaCN  $\longrightarrow$  Na<sub>4</sub>[Fe(CN)<sub>6</sub>]

(iv) 
$$CuSO_4 + 2NaCN \longrightarrow Na_2SO_4 + Cu(CN)_2$$
  
 $2Cu(CN)_2 \longrightarrow 2CuCN + (CN)_2$   
 $CuCN + 3NaCN \longrightarrow Na_3[Cu(CN)_4]$ 

A dilute solution of sodium cyanide dissolves gold and silver in presence of oxygen.

$$4Au + 8NaCN + 2H_2O + O_2 \longrightarrow 4Na[Au(CN)_2] + 4NaOH$$

## Uses

Sodium cyanide is used:

- (i) in the extraction of Ag and Au.
- (ii) as germicide in agriculture.
- (iii) in electroplating of silver, gold, etc.
- (iv) in the preparation of complex cyanides of transition metals and organic cyanides.
  - (v) as a laboratory reagent.

## 6.6 POTASSIUM

Potassium is not found in the native state. In combined state, potassium compounds are widely distributed in nature almost to the same extent as the sodium compounds. All plants contain considerable amounts of potassium compounds which they receive from soil. Its compounds occur as salt beds, in rocks and in sea water. The important minerals of potassium are:

Sylvite KCl

Carnallite  $KCl \cdot MgCl_2 \cdot 6H_2O$ 

Kainite KCl·MgSO<sub>4</sub>·MgCl<sub>2</sub>·3H<sub>2</sub>O

Indian saltpetre KNO<sub>3</sub>

Feldspar  $K_2O \cdot Al_2O_3 \cdot 6SiO_2$  (clay) Polyhalite  $K_2SO_4 \cdot MgSO_4 \cdot CaSO_4 \cdot 6H_2O$ 

Metallic potassium is not of much in demand as cheaper sodium can be used for the same purpose. Potassium is prepared by the chemical reduction of potassium chloride, KCl rather than by electrolysis of the molten chloride, as in the preparation of sodium. However, it can also be prepared by carrying electrolysis of fused potassium hydroxide or by electrolysis of fused mixture of KCl and CaCl<sub>2</sub>. Potassium is manufactured by reducing the fluoride with calcium carbide at 1000°C in steel cylinders.

$$2KF + CaC_2 \xrightarrow{1000^{\circ}C} 2K + CaF_2 + 2C$$

The metal obtained is 99.7 per cent pure.

**Uses:** (i) Potassium is used in photoelectric cells. In the commercial process, potassium chloride is melted with sodium metal by heating to 870°C.

$$KCl + Na \xrightarrow{870^{\circ} C} K + NaCl$$

At this temperature, potassium forms a vapour, which leaves the reaction chamber and then condensed in photoelectric cells.

(ii) An alloy of potassium and sodium is used in special thermometers employed for measuring high temperatures.

## Compounds of Potassium

## ■ 1. Potassium Chloride, KCl

Potassium chloride is the starting material for the preparation of various potassium compounds. It is obtained from carnallite, KCl·MgCl<sub>2</sub>·6H<sub>2</sub>O, by fractional crystallisation. The carnallite is ground and extracted with a 20 per cent solution of MgCl<sub>2</sub>. The carnallite dissolves while NaCl and MgSO<sub>4</sub> remain undissolved. The clear solution is put to crystallisation when crystals of KCl separate out.

More than 90% of the potassium chloride that is mined is used directly as a plant fertilizer. The rest is used in the preparation of various potassium compounds.

## ■ 2. Potassium Iodide, KI

## Preparation

(i) It is prepared by the action of hydroiodic acid on potassium hydroxide or potassium carbonate.

$$\begin{aligned} &KOH + HI \longrightarrow KI + H_2O \\ &K_2CO_3 + 2HI \longrightarrow 2KI + CO_2 + H_2O \end{aligned}$$

(ii) It may be prepared by heating iodine with hot and concentrated solution of potassium hydroxide. The resulting liquid consisting of KI and KIO<sub>3</sub> is evaporated to dryness and the solid residue is then ignited with powdered charcoal to convert iodate also into iodide.

$$3I_2 + 6KOH \longrightarrow 5KI + KIO_3 + 3H_2O$$
  
 $KIO_3 + 3C \longrightarrow KI + 3CO$ 

The mass is extracted with water, filtered and the clear solution is evaporated to dryness.

(iii) Potassium iodide is obtained on large scale by the action of ferroso ferric iodide on potassium carbonate. The solution is boiled.

$$4K_2CO_3 + Fe_3I_8 + 4H_2O \longrightarrow 8KI + 4CO_2 + Fe(OH)_2 \cdot 2Fe(OH)_3$$

 $[\text{Fe}_3 I_8 \text{ is formed separately by adding iodine to iron fillings in water.}$ 

Fe + 
$$I_2 \longrightarrow FeI_2$$
  
 $3FeI_2 + I_2 \longrightarrow Fe_3I_8$  (ferroso ferric iodide)]

The precipitate is filtered off and the clear solution is put to crystallisation when crystals of potassium iodide are obtained.

[Note: KBr, potassium bromide is obtained similarly by the application of above methods.]

## **Properties**

- (a) It is white crystalline solid, highly soluble in water and alcohol.
- (b) It dissolves in free iodine and forms potassium tri-iodide.

[The solubility of iodine increases in presence of potassium iodide.]

$$KI + I_2 \longrightarrow KI_3 \rightleftharpoons KI + I_2$$

Kì<sub>3</sub> is unstable and gives up extra iodine readily.

(c) Sulphuric acid decomposes potassium iodide.

$$2KI + H2SO4 \longrightarrow K2SO4 + 2HI$$

$$2HI + H2SO4 \longrightarrow 2H2O + I2 + SO2$$

$$2KI + 2H2SO4 \longrightarrow K2SO4 + I2 + SO2 + 2H2O$$

$$2KI + 3H2SO4 \longrightarrow 2KHSO4 + I2 + SO2 + 2H2O$$

(d) Chlorine liberates iodine from potassium iodide.

$$2KI + Cl_2 \longrightarrow 2KCl + I_2$$

(e) It acts as a reducing agent. Oxidising agents like acidified KMnO<sub>4</sub>, acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, HNO<sub>3</sub>, H<sub>2</sub>O<sub>2</sub>, CuSO<sub>4</sub>, etc., liberate iodine from KI.

(i) 
$$2KMnO_4 + 3H_2SO_4 \rightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5O$$
  
 $[2KI + H_2SO_4 + O \rightarrow K_2SO_4 + H_2O + I_2] \times 5$ 

$$2KMnO_4 + 10KI + 8H_2SO_4 \rightarrow 6K_2SO_4 + 2MnSO_4 + 5I_2 + 8H_2O_4$$

(ii) 
$$K_2Cr_2O_7 + 4H_2SO_4 \rightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3O$$
  
 $[2KI + H_2SO_4 + O \rightarrow K_2SO_4 + H_2O + I_2] \times 3$ 

$$6KI + K_2Cr_2O_7 + 7H_2SO_4 \rightarrow 4K_2SO_4 + Cr_2(SO_4)_3 + 3I_2 + 7H_2O$$

(iii) 
$$[CuSO_4 + 2KI \longrightarrow CuI_2 + K_2SO_4] \times 2$$
  
Unstable

The above three reactions are used in iodometric titrations.

(iv) 
$$2HNO_3 \longrightarrow H_2O + 2NO_2 + O$$
  
 $2KI + 2HNO_3 + O \longrightarrow 2KNO_3 + I_2 + H_2O$   
 $2KI + 4HNO_3 \longrightarrow 2KNO_3 + 2NO_2 + I_2 + 2H_2O$ 

(f) Potassium iodide forms insoluble iodides with AgNO<sub>3</sub> and lead salts.

$$\begin{array}{c} \text{AgNO}_3 + \text{KI} \longrightarrow \text{AgI} + \text{KNO}_3 \\ \text{Yellow} \\ \text{Pb}(\text{CH}_3\text{COO})_2 + 2\text{KI} \longrightarrow \begin{array}{c} \text{PbI}_2 + 2\text{CH}_3\text{COOK} \\ \text{Yellow} \end{array}$$

If forms a red precipitate with HgCl<sub>2</sub> which dissolves in excess of potassium iodide forming potassium mercuric iodide.

$$HgCl_2 + 2KI \longrightarrow HgI_2 + 2KCI$$
  
 $HgI_2 + 2KI \longrightarrow K_2HgI_4$ 

The alkaline solution of  $K_2HgI_4$  is called Nessler's reagent and is used for the detection and estimation of  $NH_4^+$  ion.

Uses: It is used:

- (a) as a solvent of iodine.
- (b) as a reagent in laboratory.
- (c) in medicine and photography.
- (d) for making Nessler's reagent in the laboratory.

## 3. Potassium Nitrate, KNO<sub>3</sub>

Potassium nitrate is prepared by the reaction of potassium hydroxide and nitric acid.

$$\begin{array}{c} KOH + HNO_3 \longrightarrow KNO_3 + H_2O \\ \text{Potassium} \\ \text{hydroxide} \end{array} \\ \begin{array}{c} \text{Nitric acid} \\ \text{nitrate} \end{array}$$

**Uses:** (i) KNO<sub>3</sub> is used in the production of fertilizers and for explosives and fireworks.

(ii) Potassium nitrate, KNO3, releases oxygen when heated,

$$2KNO_3(s) \xrightarrow{\Delta} 2KNO_2(s) + O_2(g)$$

and is used to facilitate the ignition of matches.

(iii) It is less hygroscopic (water absorbing) than the corresponding sodium compounds, because the K<sup>+</sup> cation is larger and is less strongly hydrated by H<sub>2</sub>O molecule.

## 4. Oxides

Three oxides of potassium are known:

- (a) potassium monoxide, K<sub>2</sub>O.
- (b) potassium dioxide (tetraoxide or superoxide),  $KO_2$  or  $K_2O_4$ .
  - (c) potassium sesquioxide, K<sub>2</sub>O<sub>3</sub>.
- (b) Potassium dioxide; (tetraoxide or superoxide) KO<sub>2</sub>: Almost all of the potassium metal produced is used in the preparation of potassium superoxide, KO<sub>2</sub>. It is prepared by burning potassium in excess of oxygen free from moisture.

$$K + O_2 \longrightarrow KO_2$$

It is also obtained by reacting dry potassium hydroxide with ozone.

$$2KOH + O_3 \longrightarrow 2KO_2 + H_2O$$

**Properties:** Potassium superoxide,  $KO_2$ , is a chrome yellow powder. It dissolves in water giving  $H_2O_2$  and  $O_2$ .

$$2KO_2 + 2H_2O \longrightarrow 2KOH + H_2O_2 + O_2$$

It reacts directly with CO and CO<sub>2</sub>.

$$2KO_2 + CO \longrightarrow K_2CO_3 + O_2$$
  
 $4KO_2 + 2CO_2 \longrightarrow 2K_2CO_3 + 3O_2$ 

On heating with sulphur, it forms potassium sulphate.

$$2KO_2 + S \longrightarrow K_2SO_4$$

**Uses:** KO<sub>2</sub> is used as an oxidising agent. It is used as air purifier in space capsules, submarines and breathing masks as in all these it produces oxygen and removes carbon dioxide.

(c) Potassium sesquioxide;  $K_2O_3$ : It is obtained when oxygen is passed through liquid ammonia containing potassium.

4K (dissolved in liquid NH<sub>3</sub>) 
$$\xrightarrow{3O_2}$$
 2K<sub>2</sub>O<sub>3</sub>

Uses: It is used for the production of self contained breathing apparatus which is used in the situations such as fire fighting, where toxic fumes may be present.

## ■ 5. Potassium Hydroxide (Caustic Potash), KOH

It was first prepared from potassium carbonate (K<sub>2</sub>CO<sub>3</sub>), obtained by leaching plant ashes with water and evaporating the solution in large pots (whence the name).

It is manufactured like sodium hydroxide, *i.e.*, by electrolysis of aqueous KCl solution.

Uses: It is an important base and is used for the absorption of gases like CO<sub>2</sub>, SO<sub>2</sub>, etc. It is often called as **caustic potash** and its aqueous solution is known as **potash lye.** It is used for making soft and liquid soaps.

Alcoholic caustic potash is a useful reagent in organic chemistry as it eliminates hydrogen halides from alkyl halides.

$$C_2H_5Br + KOH(alc.) \longrightarrow C_2H_4 + KBr + H_2O$$

Like caustic soda, NaOH caustic potash, KOH also is quite corrosive and destructive to the organic tissue; they convert animal fats to soaps.

## ■ 6. Potassium Carbonate, K<sub>2</sub>CO<sub>3</sub>

It is also called **Potash** or **Pearl ash.** It cannot be made by the use of Solvay process as potassium bicarbonate is more soluble than sodium bicarbonate. However, it can be prepared by **Le-Blanc process.** KCl is first converted into  $K_2SO_4$ . Potassium sulphate  $(K_2SO_4)$  is then heated with  $CaCO_3$  and carbon.

$$KCl + H_2SO_4 \longrightarrow KHSO_4 + HCl$$
  
 $KHSO_4 + KCl \longrightarrow K_2SO_4 + HCl$ 

$$K_2SO_4 + CaCO_3 + 2C \longrightarrow K_2CO_3 + CaS + 2CO_2$$

It is a white powder, deliquescent in nature. It is highly soluble in water.

Uses: It is used in the manufacture of hard glass. The mixture of  $K_2CO_3$  and  $Na_2CO_3$  is used as a fusion mixture in laboratory.

## **Example 3.** Explain the following:

- (a) Sodium carbonate is made by Solvay process but the same process is not extended to the manufacture of potassium carbonate.
- (b) On exposure to air, sodium hydroxide becomes liquid and after sometimes it changes to white powder.
- (c) Alkali metals are obtained by the electrolysis of the molten salts and not by the electrolysis of their aqueous solutions.

- (d) Calcium chloride is added to NaCl in the electrolytic manufacture of sodium.
- (e) An aqueous solution of iodine becomes colourless on adding excess of sodium hydroxide solution.

## **Solution:**

- (a) KHCO<sub>3</sub>, the intermediate, is very soluble in water and cannot be obtained in solid state as NaHCO<sub>3</sub> is formed in Na<sub>2</sub>CO<sub>3</sub> manufacture.
- (b) Sodium hydroxide continuously absorbs carbon dioxide and moisture of atmosphere and is converted into sodium carbonate solution.

A stage reaches when the solution becomes saturated and the crystals are formed. These crystals, with the passage of time, lose water of crystallisation (efflorescence) and crumble to white powder.

(c) The solutions of alkali metal salts contain metal cations, H<sup>+</sup>, OH<sup>-</sup> and the anions. The discharge potential of H<sup>+</sup> ions is lower than the metal cations and thus, on electrolysis of solutions of alkali metal salts, hydrogen is discharged at cathode rather than the metal.

However, on electrolysis of molten salt, the metal cation only present gets discharged at cathode.

- (d) Pure sodium chloride melts at about 800°C. At this temperature both sodium and chlorine (products of electrolysis) are corrosive in nature. Sodium also forms a metallic fog at this temperature. To remove these difficulties, the fusion temperature is reduced to 600°C by adding CaCl<sub>2</sub>.
- (e) Iodine reacts with NaOH forming colourless compounds. Thus, the colour of iodine disappears on addition of NaOH.

$$2NaOH \, + \, I_2 \longrightarrow \underbrace{NaI + NaIO}_{Colourless \; products} \, + \, H_2O$$

Example 4. How would you prepare the following?

- (a) Sodium thiosulphate from sodium carbonate.
- (b) Microcosmic salt from disodium hydrogen phosphate.
- (c) Sodium carbonate from sodium chloride.
- (d) Sodium thiosulphate from sodium sulphite.
- (e) Sodium cyanide from metallic sodium.

## **Solution:**

(a) Sodium carbonate is first converted into sodium sulphite by passing sulphur dioxide.

$$Na_2CO_3 + SO_2 \longrightarrow Na_2SO_3 + CO_2$$

The solution of Na<sub>2</sub>SO<sub>3</sub> is then boiled with sulphur for two hours.

$$Na_2SO_3 + S \longrightarrow Na_2S_2O_3$$

(b) It is prepared by dissolving NH<sub>4</sub>Cl in disodium hydrogen phosphate in molecular proportion in hot water.

(c) The conversion is made by Solvay process.

$$CO_2 + NH_3 + H_2O \longrightarrow NH_4HCO_3$$
  
 $NH_4HCO_3 + NaCl \longrightarrow NaHCO_3 + NH_4Cl$   
 $2NaHCO_3 \longrightarrow Na_2CO_3 + H_2O + CO_2$ 

(d) The solution of sodium sulphite is boiled with sulphur in an iron retort for two hours.

$$Na_2SO_3 + S \longrightarrow Na_2S_2O_3$$

(e) Sodium is first converted into sodamide by passing dry ammonia gas over heated sodium.

$$2Na + 2NH_3 \longrightarrow 2NaNH_2 + H_2 \uparrow$$

The liquid sodamide is then dropped over red hot charcoal.

$$2NaNH_2 + C \longrightarrow Na_2CN_2 + 2H_2$$
 Sod. cyanamide

$$Na_2CN_2 + C \longrightarrow 2NaCN$$

**Example 5.** 'A' is a binary compound of a univalent metal. 1.422 g of 'A' reacts completely with 0.321 g of sulphur in an evacuated and sealed tube to give 1.743 g of a white crystalline solid 'B', that forms a hydrated double salt 'C' with  $Al_2(SO_4)_3$ . Identify 'A', 'B' and 'C'. [I.I.T. 1994]

## Solution:

Since 'B' forms a hydrated double salt with  $Al_2(SO_4)_3$ . 'B' should be a sulphate of a monovalent metal, i.e.,  $M_2SO_4$ . As the sulphate  $(M_2SO_4)$  consists one sulphur atom per molecule, its molecular mass can be determined from the given data.

0.321 g of sulphur is present in 1.743 g of sulphate

32.1 g of sulphur is present in 
$$=\frac{1.743}{0.321} \times 32.1 = 174.3$$
 g

Thus, the molecular mass of the sulphate is 174.3. Let the atomic mass of the metal be x.

So 
$$2x + 32.1 + 64 = 174.3$$
  
 $2x = 174.3 - 96.1 = 78.2$   
 $x = 39.1$ 

Thus, 'B' is 
$$K_2SO_4$$
 and 'C' is  $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$   
2 [Oxide] + S  $\longrightarrow K_2SO_4$ 

Thus, the oxide is  $KO_2$  (potassium superoxide). The given data supports that 'A' is  $KO_2$ .

**Example 6.** (i) An inorganic compound (A) is formed on passing a gas (B) through a concentrated liquor containing sodium sulphide and sodium sulphite.

- (ii) On adding (A) into dilute solution of silver nitrate, a white precipitate appears which quickly changes into a black coloured compound (C).
- (iii) On adding two or three drops of ferric chloride into the excess of solution of (A), a violet coloured compound (D) is formed. This colour disappears quickly.
- (iv) On adding a solution of (A) into the solution of cupric chloride, a white precipitate is first formed which dissolves on adding excess of (A) forming a compound (E).

Identify (A) to (E) and give the chemical equations for the reactions at steps (i) to (iv). [Roorkee 1996]

## Solution:

The reactions indicate that the compound (A) is sodium thiosulphate. It is formed in step (i) by passing gas (B) which is either  $I_2$  or  $SO_2$ .

**Example 7.** A white solid is either  $Na_2O$  or  $Na_2O_2$ . A piece of red litmus paper turns white when it is dipped into a freshly made aqueous solution of the white solid.

- (i) Identify the substance and explain with balanced equation.
- (ii) Explain what would happen to the red litmus if the white solid were the other compound. [I.I.T. 1999]

### Solution:

(i) A piece of red litmus turns white when dipped into aqueous solution of white solid indicates that the solution has bleaching action on litmus. This is due to the presence of hydrogen peroxide in solution which is formed by action of water on sodium peroxide. Thus, the white solid is Na<sub>2</sub>O<sub>2</sub>.

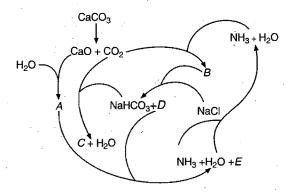

$$Na_2O_2 + 2H_2O \longrightarrow 2NaOH + H_2O_2$$

(ii) The other compound is Na<sub>2</sub>O which gives NaOH (sodium hydroxide) with water.

$$Na_2O + H_2O \longrightarrow 2NaOH$$

The solution, thus, turns red litmus to blue.

**Example 8.** The Solvay process can be represented by the following scheme:

Identify A, B, C, D and E.

[I.I.T. 1999]

## **Solution:**

 $(A): Ca(OH)_2$ 

$$CaO + H_2O \longrightarrow Ca(OH)_2$$
(A)

 $(B): NH_4HCO_3$ 

$$NH_3 + H_2O + CO_2 \longrightarrow NH_4HCO_3$$
(B)

(C):  $Na_2CO_3$ 

$$2$$
NaHCO<sub>3</sub>  $\longrightarrow$  Na<sub>2</sub>CO<sub>3</sub> + H<sub>2</sub>O + CO<sub>2</sub>

 $(D): NH_4Cl$ 

$$NH_4HCO_3 + NaCl \longrightarrow NaHCO_3 + NH_4Cl$$
(D)

(E): CaCl<sub>2</sub>

$$2NH_4Cl + Ca(OH)_2 \longrightarrow 2NH_3 + 2H_2O + CaCl_2$$
(E)

**Example 9.** (a) Sodium fire in the laboratory should not be extinguished by pouring water. Why?

- (b) Alkali metals are paramagnetic but their salts are diamagnetic. Explain.
- (c) Why superoxides of alkali metals are paramagnetic while normal oxides are diamagnetic?

### **Solution**:

- (a) Sodium being highly electropositive element reacts vigorously with water evolving hydrogen which also catches fire. As a result, the fire spreads. Therefore, water should not be used to extinguish sodium fire.
- (b) Alkali metals possess ns<sup>1</sup> configuration, i.e., one unpaired electron is present and hence are paramagnetic. Alkali metals when form salts, the unpaired electron is transferred to the non-metallic atom forming anion. In salts, both cations and anions have paired electrons and hence, alkali metal salts are diamagnetic in nature.

(c) Superoxides contain the ion,  $O_2^-$  which has the following structure:

It has a three electron bond, *i.e.*, one unpaired electron is present and hence, is paramagnetic. Normal oxides contain the ion, O<sup>2-</sup>, which does not has unpaired electron and thus, are diamagnetic in nature.

**Example 10.** Comment on each of the following observations:

- (a) Lithium is the only alkali metal which forms nitride directly.
- (b) LiF is almost insoluble in water while LiCl is soluble in water as well as in acetone.
- (c) The mobilities of alkali metal ions in aqueous solutions are:

$$Li^+ < Na^+ < K^+ < Rb^+$$

## **Solution:**

(a) As it shows diagonal relationship with magnesium, it directly combines with nitrogen like magnesium and forms nitride.

$$6Li + N_2 \longrightarrow 2Li_3N$$

- (b) Lattice energy of LiF is very large as both Li<sup>+</sup> and F ions are small in size. Hence, LiF is almost insoluble in water. LiCl is partially covalent in nature due to polarisation of chloride ion by Li<sup>+</sup>. Thus, it is soluble in water as well as in acetone.
- (c) The degree of hydration is more for smaller ions. Thus, the mass of the hydrated ions follows the following order,

$$[\text{Li}(aq)]^+ > [\text{Na}(aq)]^+ > [\text{K}(aq)]^+ > [\text{Rb}(aq)]^+.$$

Therefore, the ionic mobility follows the following order:

$$[\text{Li}(aq)]^+ < [\text{Na}(aq)]^+ < [\text{K}(aq)]^+ < [\text{Rb}(aq)]^+$$

## •

## **SUMMARY AND IMPORTANT POINTS TO REMEMBER**

- 1. The group 1 or IA of the periodic table consists of six elements-lithium, sodium, potassium, rubidium, caesium and francium besides hydrogen. These elements are called alkali metals as the hydroxides of these elements are soluble in water and these solutions are highly alkaline in nature. Alkali is an Arabic word 'Alquili' meaning the ashes of plants from which compounds of sodium and potassium were first isolated.
- 2. The alkali metals are s-block elements as the last electron enters ns-orbital. They have [noble gas] ns<sup>1</sup> electronic configuration. The first member lithium, shows somewhat abnormal properties then rest of the members of the group as the penultimate shell in Li has two electrons while in rest of the alkali elements eight electrons are present in the penultimate shell.
- 3. The alkali metals, being reactive in nature, are never found free in nature but always found in combined state. Sodium and potassium are found in abundance as they are seventh and eighth most abundant elements by mass in earth's crust. The last member, francium, is radioactive and occurs only in traces as its half life is very small, *i.e.*, 21 minutes.
- 4. Except first period, rest of the six periods of the periodic table start with a member of alkali group. It is a most homogeneous group. The members of this group show a marked resemblance in their properties. There is a gradual gradation in the properties with the increase of atomic number.

## 5. Physical properties

(a) Alkali metals are soft with low melting and boiling points. This is due to weak intermetallic bonding. All are light metals having low densities. Densities increase from I to Cs with exception of K.

- (b) Alkali metals have the largest size in their respective periods. Atomic as well as ionic size increases as the at. no. increases from Li to Cs. At. volume also increases as the atomic number increases.
- (c) The ionisation energy decreases from Li to Cs as their size increases. They are highly electropositive, metallic in nature and reactivity increases from Li to Cs. All except lithium show photoelectric effect.
- (d) All alkali metals are paramagnetic but their salts are diamagnetic in nature. The alkali metals show only one oxidation state, *i.e.*, +1 in their compounds.
- (e) Alkali metals and their compounds impart characteristic colour to flame.

Li Na K Rb Cs Crimson red Golden yellow Pale violet Reddish violet Sky blue

- (f) The salts of alkali metals are ionic and soluble in water. The solubility is due to hydration of  $M^+$  ions. Smaller the ion, the greater is the degree of hydration. The degree of hydration decreases from Li<sup>+</sup> to Cs<sup>+</sup>. Consequently, the radii of the hydrated ion decreases from Li<sup>+</sup> to Cs<sup>+</sup>.
- (g) Due to large negative electrode potentials, alkali metals are strong reducing agents. The reducing nature increases from Na to Cs but Li is the strongest reducing agent as its reduction potential is highest, i.e, -3.05. This is due to large heat of hydration of Li<sup>+</sup> ion.
- (h) The alkali metals are good conductors of heat and electricity.

## 6. Chemical properties

The alkali metals are highly reactive elements. The reactivity is due to:

- (i) low value of ionisation energy
- (ii) low heat of atomisation.

The reactivity increases from Li to Cs. The compounds of alkali metals are electrovalent, colourless and soluble in water. These are crystalline solids. Lithium compounds show some abnormal properties due to polarisation on account of small size of Li<sup>+</sup> ion and high lattice energies.

- (a) On exposure to moist air, all alkali metals except lithium tarnish quickly. These are, therefore, always kept in kerosene to protect them from air.
- (b) Alkali metals decompose water with evolution of hydrogen. The reactivity towards water increases from Li to Cs. The decomposition is highly exothermic and the evolved hydrogen sometimes catches fire.
- (c) Alkali metals combine directly with hydrogen to form crystalline solids of formula MH. The hydrides react with water liberating hydrogen.
- (d) Affinity towards oxygen increases when heated in atmosphere of oxygen, the alkali metals ignite and form oxides.

The peroxides and superoxides become more stable with increase in atomic number of the alkali metal. The basic nature of the normal oxides increases gradually as the atomic number increases. The hydroxides (MOH) are thermally stable except LiOH. The relative strength of the hydroxides increases from LiOH to CsOH.

 $Li_2O < Na_2O < K_2O < Rb_2O < Cs_2O$ LiOH < NaOH < KOH < RbOH < CsOH

Basic nature increases -----

The higher oxides, peroxides and superoxides are strong oxidising agents. They react with water and dilute acids forming H<sub>2</sub>O<sub>2</sub> and O<sub>2</sub>.

- (e) The alkali metals directly react with halogens forming halides (MX). With the exception of lithium halides, the alkali metal halides are ionic compounds. They are crystalline and have high melting and boiling points. The fused halides are good conductors of electricity. Alkali metal halides are colourless but on heating they turn yellow, blue, etc., due to crystal defects. Except LiF, all halides are soluble in water. The insolubility of LiF is due to high lattice energy. Halides of K, Rb and Cs have a property of combining with extra halogen atoms forming polyhalides.
- (f) Alkali metals directly combine with P and S when heated with them. Alkali metals, except lithium, do not combine directly with nitrogen.
- (g) All the alkali metals form carbonates of type  $M_2CO_3$ . Carbonates are stable towards heat and readily soluble in water. Li<sub>2</sub>CO<sub>3</sub> is an exception.

The aqueous solutions of carbonates are alkaline due to hydrolysis.

The bicarbonates (MHCO<sub>3</sub>) with the exception of LiHCO<sub>3</sub>, are known in solid state.

They are soluble in water and decompose on heating into corresponding carbonate with evolution of CO<sub>2</sub>.

- (h) Nitrates of the type, MNO<sub>3</sub>, are known. These are colour-less, soluble in water and electrovalent in nature. With the exception of LiNO<sub>3</sub>, the other nitrates decompose to nitrites and oxygen on heating. LiNO<sub>3</sub> decomposes to oxide with evolution of NO<sub>2</sub> and O<sub>2</sub>.
- (i) Sulphates of the type M<sub>2</sub>SO<sub>4</sub> are known with the exception of Li<sub>2</sub>SO<sub>4</sub>, other sulphates are soluble in water. Sulphates are reduced to corresponding sulphides when fused with carbon. Sulphates of alkali metals form double salts with the sulphates of trivalent metals like Fe, Al, Cr, etc.
- (j) The alkali metals dissolve in liquid ammonia without evolution of hydrogen. The colour of dilute solutions is blue. On heating colour changes to bronze. The colour is due to ammoniated electron.

 $M + (x + y) \text{ NH}_3 \longrightarrow [M(\text{NH}_3)_x]^+ + e(\text{NH}_3)_y$ These solutions are good conductors of electricity and have strong reducing properties. The solutions are paramagnetic in nature.

When dry ammonia is passed over hot metal, amides are formed.

7. The alkali metals form alloys amongst themselves and with other metals. These combine with mercury and form amalgams.

- **8.** Alkali metals have a very little tendency to form complexes. Lithium being small in size forms certain complexes but this tendency decreases as the size increases.
- 9. Alkali metals cannot be extracted by application of common processes used for the extraction of metals due to following reasons:
  - (i) Cannot be extracted by the reduction of their oxides and other compounds as being strong reducing agents.
  - (ii) Cannot be extracted by displacing them from their salt solutions by any other element as they are highly electropositive.
  - (iii) Cannot be extracted by electrolysis of the aqueous solutions of their salts as hydrogen is discharged at cathode instead of alkali metal.

The only successful method, therefore, is the electrolysis of their fused salts usually chlorides. Generally, another metal chloride is added to lower its fusion temperature.

- 10. Lithium shows abnormal properties due to its small size (atom and ion). Lithium ion on account of its small size exerts polarising effect on negative ions. Consequently, covalent character is developed in Li-salts. Li has highest ionisation energy and electronegativity as compared to other alkali metals.
  - (i) LiCl is more covalent than NaCl. LiCl is soluble in alcohol, pyridine, etc. Its melting point is lower than that of NaCl.
  - (ii) LiOH, Li<sub>2</sub>CO<sub>3</sub>, LiNO<sub>3</sub> behave differently than other alkali corresponding salts towards heating.

$$2\text{LiOH} \longrightarrow \text{Li}_2\text{O} + \text{H}_2\text{O}; \quad \text{Li}_2\text{CO}_3 \longrightarrow \text{Li}_2\text{O} + \text{CO}_2; 4\text{LiNO}_3 \longrightarrow 2\text{Li}_2\text{O} + 4\text{NO}_2 + \text{O}_2$$

Hydroxides and carbonates of other alkali metals are stable. The nitrates of other alkali metals decompose giving only oxygen.

(iii) Lithium directly combines with nitrogen.

$$.6 \text{ Li} + \text{N}_2 \longrightarrow 2 \text{Li}_3 \text{N}$$

- (iv) LiHCO3 is known only in solution but not in solid state.
- (v) Li<sub>2</sub>SO<sub>4</sub> does not form double sulphates.
- (vi) LiF, Li<sub>3</sub>PO<sub>4</sub>, Li<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, Li<sub>2</sub>CO<sub>3</sub> are sparingly soluble in water.
- (vii) LiOH is weaker base in comparison to NaOH or KOH.
- (viii) Although Li has the highest ionisation potential, yet it is strongest reducing agent because of its large heat of hydration.
- 11. Lithium shows resemblance with magnesium, an element of group II A. This resemblance is termed diagonal relationship. The reasons for this resemblance are: (i) nearly same electronegativity (ii) not much difference in atomic size and ionic size (iii) nearly same atomic volumes (iv) nearly same polarising power.
- 12. Important minerals of sodium are: (i) chile saltpetre (NaNO<sub>3</sub>) (ii) Glauber's salt (Na<sub>2</sub>SO<sub>4</sub>·10H<sub>2</sub>O) (iii) trona (Na<sub>2</sub>CO<sub>3</sub>·2NaHCO<sub>3</sub>·3H<sub>2</sub>O) (iv) natron (Na<sub>2</sub>CO<sub>3</sub>·H<sub>2</sub>O) (v) tincal or borax (Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O) (vi) cryolite (Na<sub>3</sub>AlF<sub>6</sub>) (vii) soda felspar (NaAlSi<sub>3</sub>O<sub>8</sub>) (viii) common salt or rock salt or sea salt (NaCl).
- 13. Sodium is obtained on large scale by two processes.
  - (a) Castner's process: Electrolysis of fused sodium hydroxide is carried at 330°C using iron as cathode and nickel as anode. Hydrogen is discharged at cathode also.

(b) **Down's process:** Now-a-days, this process is applied. It involves electrolysis of fused NaCl to which CaCl<sub>2</sub> and KF have been added to reduce the melting point of NaCl. Iron is used as cathode and graphite as anode.

The electrolysis is carried at 600°C. Chlorine is discharged at anode.

- 14. Sodium is used in the manufacture of chemicals like Na<sub>2</sub>O<sub>2</sub> (oxone), sodamide, sodium cyanide, etc. It is used for making lead tetraethyl employed as antiknock in petrol. In molten state, it is used in nuclear reactors as heat transfer medium. For extraction of C, Be, Mg, Si, etc., in sodium lamps and as a laboratory reagent, sodium metal is also used.
- 15. The main source of NaCl is sea water which contains 2.7-2.9 % of the salt. Table salt becomes wet in rainy season due to presence of impurities of MgCl<sub>2</sub> and CaCl<sub>2</sub>.
- **16.** Sodium carbonate (washing soda), Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O, is generally prepared by a process called ammonia-soda process or Solvay process. The raw materials are NaCl, NH<sub>3</sub> and limestone.

$$NH_3 + H_2O + CO_2 \longrightarrow NIH_4HCO_3$$
 $NaCl + NH_4HCO_3 \longrightarrow NaHCO_3 + NH_4Cl$ 
 $2NaHCO_3 \longrightarrow Na_2CO_3 + H_2O + CO_2$ 

Solvay process cannot be employed for the manufacture of  $K_2CO_3$  because KHCO<sub>3</sub> is fairly soluble in water.

A mixture of NaHCO<sub>3</sub> and potassium hydrogen tartrate is called baking powder while sodium bicarbonate alone is called baking soda.

A mixture of Na<sub>2</sub>CO<sub>3</sub> and K<sub>2</sub>CO<sub>3</sub> is called fusion mixture. Anhydrous Na<sub>2</sub>CO<sub>3</sub> is called soda ash and obtained by heating Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O above 100°C. Sodium carbonate is used in laundries and in softening of water. It is used in the manufacture of glass, sodium silicate, borax, paper, soap powders, caustic soda, etc.

NaHCO<sub>3</sub> is used for making baking powder, in making effervescent drinks, in fire extinguishers and as a medicine.

- **17.** Sodium hydroxide (caustic soda) is manufactured on a very large scale by the following processes:
  - (i) Gossage process: Sodium carbonate reacts with suspension of lime (milk of lime or calcium hydroxide).

 $Na_2CO_3 + Ca(OH)_2 \longrightarrow 2NaOH + CaCO_3$ Calcium carbonate being insoluble separates out and the solution on evaporation gives flakes of caustic soda.

(ii) Lowig's process: A mixture of sodium carbonate and ferric oxide is heated to redness. Sodium ferrite is formed. The cooled sodium ferrite is thrown into hot water when hydrolysis occurs forming a solution of NaOH and insoluble ferric oxide.

$$Na_2CO_3 + Fe_2O_3 \longrightarrow 2NaFeO_2 + CO_2$$
  
 $2NaFeO_2 + H_2O \longrightarrow 2NaOH + Fe_2O_3$ 

- (iii) Electrolytic process: The electrolysis of sodium chloride is carried out in an electrolytic cell. The following electrolytic cells are used:
- (a) Nelson cell: It consists a perforated steel tube lined inside with asbestos. The tube acts as a cathode. A graphite rod dipped in sodium chloride solution serves as anode.
- **(b) Castner-Kellner cell:** This is a common cell in which mercury is used as cathode. The cell consists of a large

rectangular trough divided into three compartments by slate partitions. The mercury can flow from one compartment to other but the solution kept in one compartment cannot flow into other. Sodium chloride solution is kept in two outer compartments and a dilute solution of NaOH in the inner compartment. Two graphite electrodes which act as anodes are fitted in outer compartments and a series of iron rods fitted in the inner compartment act as cathode. Mercury in the outer compartments acts as cathode while in the inner compartment it acts as an anode by induction. The cell is kept rocking with the help of an eccentric wheel. Sodium discharged at the Hg cathode in the outer compartments forms amalgam which comes into the inner compartment due to rocking. Here, NaOH is formed.

(c) Keliner-Solvay cell: This is the modified cell having no compartments. Flowing Hg acts as cathode and a number of graphite rods act as anode in sodium chloride solution. The sodium amalgam flows out of cell and treated with water to form NaOH.

Commercial NaOH is purified with the help of alcohol. The alcoholic filtrate is distilled to get pure NaOH.

- 18. NaOH is a white crystalline solid. It has a soapy touch. It is highly deliquescent. It is highly soluble in water. It is a strong alkali. It cannot be kept in atmosphere as it absorbs moisture and CO<sub>2</sub>. It reacts with acids, acidic oxides and amphoteric oxides to form salts. It attacks non-metals like S, P, Si, B, halogens, etc. Metals like Zn, Al, Sn, Pb react with NaOH evolving H<sub>2</sub>. A number of metallic salts react with NaOH to form corresponding hydroxides. Ammonium salts evolve ammonia with NaOH. NaOH combines with CO under pressure to form sodium formate.
- 19. NaOH is used as a laboratory reagent, in manufacture of soap, in manufacture of paper and rayon, dyes and drugs. It is an absorber of gases. It is used in petroleum refining and for the manufacture of various useful sodium compounds.
- 20. Sodium peroxide (oxone), Na<sub>2</sub>O<sub>2</sub>, is formed by heating sodium at about 350°C in excess of air free from moisture. It is a pale yellow powder. It is used as an oxidising agent, for purification of air, for production of oxygen under the name oxone and for the preparation of H<sub>2</sub>O<sub>2</sub> and benzoyl peroxide.
- 21. Potassium is not found in the native state. In combined state it is widely distributed in nature. All plants contain considerable amount of potassium compounds. Its compounds

occur as salt beds in rocks and in sea water. The important minerals of potassium are :

Carnallite (KCl-MgCl<sub>2</sub>·6H<sub>2</sub>O), Indian saltpetre (KNO<sub>3</sub>), feldspar ( $K_2O \cdot Al_2O_3 \cdot 6SiO_2$ ), sylvine (KCl), polyhalite ( $K_2SO_4 \cdot MgSO_4 \cdot CaSO_4 \cdot 6H_2O$ ), etc.

22. Potassium can be prepared by electrolysis of fused mixture of KCl and CaCl<sub>2</sub>. It is manufactured by reducing fluoride with calcium carbide at 1000°C.

$$2KF + CaC_2 \longrightarrow 2K + CaF_2 + 2C$$

Potassium is used in photoelectric cells. An alloy of potassium and sodium is used in special thermometers employed for measuring high temperatures.

23. Three oxides of potassium are known: (i) potassium monoxide, K<sub>2</sub>O (ii) potassium dioxide, KO<sub>2</sub> (iii) potassium sesquioxide, K<sub>2</sub>O<sub>3</sub>.

 $KO_2$  is prepared by burning potassium in excess of oxygen free from moisture. It is a chrome yellow powder. It dissolves in water giving  $H_2O_2$  and  $O_2$ . It is used as an oxidising agent, as air purifier in space capsules, submarines and breathing masks as it produces oxygen and removes  $CO_2$ .

KO<sub>2</sub> has bond order 1.5 and possesses paramagnetic nature due to the presence of one unpaired electron.

**24.** K<sub>2</sub>CO<sub>3</sub> is called potash or pearl ash. It is prepared by Le-Blanc process,

$$KCl \longrightarrow K_2SO_4 \xrightarrow{CaCO_3+C} K_2CO_3$$

it is used in the manufacture of hard glass.

KHCO<sub>3</sub> resembles NaHCO<sub>3</sub> in all respects except that it is more soluble in water. It is used in medicine and in baking powders.

- **25.** Caustic potash, KOH, is manufactured like NaOH, *i.e.*, by electrolysis of KCl. It is used for making soft soaps.
- Although both NaCN and KCN are poisonous but KCN is more poisonous than NaCN.
- 27. Na<sub>2</sub>SO<sub>4</sub>·10H<sub>2</sub>O is called Glauber's salt, anhydrous Na<sub>2</sub>SO<sub>4</sub> is called salt cake, NaHSO<sub>4</sub> is called nitre cake.
- **28.** Sodium thiosulphate, Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, is used as antichlor in bleaching.
- 29. Electric eye used in television contains an alloy of caesium and silver.
- **30.** All alkali metal azides are thermally unstable and liberate nitrogen and metal on heating. Lithium azide (LiN<sub>3</sub>) is an exception. It forms stable nitride on heating.

$$3\text{LiN}_3 \longrightarrow \text{Li}_3\text{N} + 4\text{N}_2$$

## ■ Subjective Type Questions

PRACTICE

## 1. Answer the following:

- (a) Why does table salt get wet in rainy season?
- (b) Which out of sodium or potassium has higher boiling point?
- (c) Why caesium is used in photoelectric cell while lithium cannot be?
- (d) What makes lithium to show properties different than other alkali metals?

#### 2. Give reasons:

- (a) LiCl is soluble in alcohol.
- (b) MgCl<sub>2</sub> is more covalent than NaCl.
- (c) LiBr has lower melting point than LiF.

## 3. Answer the following:

- (a) Name the alkali metals which form superoxides when heated in excess of air.
- (b) Which one is soluble in water?

(c) Which one is soluble in NaOH?

Al(OH)<sub>3</sub> or Fe(OH)<sub>3</sub>

- (d) Which alkali metal is radioactive in nature?
- (e) Name the alkali metal which shows diagonal relationship?
- (f) Which alkali metal is strongest reducing agent in aqueous solution.

## 4. Answer the following:

- (a) Which is the most abundant alkali metal in the earth's crust?
- (b) Which sodium salt is found in plenty in sea water?
- (c) Name one silicate and one phosphate ore of lithium.
- (d) Write the formulae of:
  - (i) Caustic potash (ii) Soda ash (iii) Chile saltpetre
- (e) Which compound of sodium is used for making baking powder?

## 5. Answer the following:

- (i) What is meant by black ash?
- (ii) What is the action of NaOH on ammonium salts?
- (iii) Which electrolyte is used to obtain sodium in Castner's process?
- (iv) What is washing soda?
- (v) Which electrolyte is used in Nelson's cell?
- (vi) What is the intermediate product in Solvay's process?
- (vii) Most abundant alkali metal in the earth's crust is :
- (viii) Which chloride of an alkali metal is soluble in alcohol?
- (ix) Which substance is added to sodium chloride as to reduce its fusion temperature during manufacture of sodium?
- (x) What product is formed when carbon monoxide is passed through sodium hydroxide under high pressure?
- **6.** What happens when following are heated?
  - (i) Potassium nitrate
- (ii) Sodium carbonate
- (iii) Microcosmic salt
- (iv) Sodium bicarbonate
- (v) Lithium hydroxide
- (vi) Lithium nitrate
- (vii) Lithium carbonate
- (viii) Sodium thiosulphate
- 7. What happens when?
  - (a) Hot and concentrated caustic soda solution reacts with iodine.
  - (b) White phosphorus is heated with caustic soda.
  - (c) Sodium thiosulphate is added to silver nitrate solution.
  - (d) Iodine is reacted with hypo solution.
  - (e) Excess of caustic soda reacts with zinc sulphate solution.
  - (f) Excess of NaOH is added to AlCl<sub>3</sub> solution.
  - (g) Anhydrous potassium nitrate is heated with excess of metallic potassium. [I.I.T. 1992]
  - (h) Copper sulphate reacts with potassium iodide.
  - (i) Copper sulphate is treated with hypo.
  - (j) Sodium is strongly heated in oxygen and the product is treated with H<sub>2</sub>SO<sub>4</sub>.
- 8. Complete and balance the following equations:
  - (i)  $KO_2 + H_2O \longrightarrow \dots + O_2$
  - (ii)  $NaNH_2 + C \longrightarrow \dots + H_2$
  - (iii)  $PbO_2 + NaOH \xrightarrow{Heat} \dots + H_2O$ (Conc.)

- (iv)  $KI + H_2SO_4 + H_2O_2 \longrightarrow I_2 + \dots + H_2O$
- (v) NaOH +  $I_2 \longrightarrow \dots + NaIO_3 + H_2O$ 9. Write the balanced equations of the reactions of:
  - (a) Caustic soda on the following:
    - (i) zinc, (ii) silver nitrate, (iii) phosphorus,
    - (iv) arsenious oxide
  - (b) Hypo on the following:
    - (i) FeCl<sub>3</sub>, (ii) AgCl, (iii) CuSO<sub>4</sub>, (iv) I<sub>2</sub>
- 10. Explain the following:
  - (i) Sodium is less reactive than potassium.
    - [**Hint**: Ionisation potential of potassium is less than sodium, *i.e.*, the tendency to lose valency electron is more in potassium than sodium.]
  - (ii) Alkali metals are paramagnetic but their salts are diamagnetic.
    - [Hint: In metals, the outermost energy shell is singly occupied but in cations, all the orbitals are doubly occupied (inert gas configuration).]
  - (iii) Sodium salts in aqueous solutions are either neutral or alkaline in nature.
    - [Hint: The anions in sodium salts are either from strong acids or weak acids. When anions from strong acids, there is no hydrolysis and aqueous solutions are neutral (NaCl soln.). On the other hand when anions from weak acids, there is hydrolysis of anions and the solutions are alkaline in nature (Na<sub>2</sub>CO<sub>3</sub> soln.).

$$CO_3^{2-} + H_2O \rightleftharpoons HCO_3^{-} + OH^{-}$$
  
 $HCO_3^{-} + H_2O \rightleftharpoons H_2CO_3^{-} + OH^{-}$ 

- (iv) Standard solution of NaOH cannot be prepared by direct weighing.
  - [Hint: NaOH is affected by atmosphere. It absorbs moisture and CO<sub>2</sub> from atmosphere. Thus, accurate weighing of NaOH is not possible.]
- (v) Commercial common salt becomes slightly damp on keeping.
  - [Hint: Pure NaCl is not hygroscopic. The commercial common salt consists small amounts of magnesium chloride and calcium chloride which absorb moisture from atmosphere making it damp.]
- (vi) Sodium metal can be used for drying diethyl ether but not ethanol.
  - [Hint: Sodium metal reacts with ethanol,  $2C_2H_5OH + 2Na \longrightarrow 2C_2H_5ONa + H_2$  and thus cannot be used for its drying.]
- (vii) A sodium fire in laboratory is not extinguished by water.
  - [Hint: Sodium reacts with water to produce hydrogen which is also inflammable. Pyrene (CCl<sub>4</sub>) can be used for this purpose.]
- (viii) The hydroxides of aluminium and iron are insoluble in water but NaOH is used to separate one from the other.

  [I.I.T. 1991]
  - [Hint: Al(OH)<sub>3</sub> dissolves in excess of NaOH forming a soluble compound, sodium meta aluminate.

    Al(OH)<sub>3</sub> + NaOH → NaAlO<sub>2</sub> + 2H<sub>2</sub>O]
- (ix) The inside surface of a glass bottle containing caustic soda becomes dull.

- [Hint: Silica is present in glass. It dissolves in NaOH slowly and forms soluble sodium silicate and thus inside surface becomes dull.]
- (x) Amongst LiF and LiI which has more covalent character and why?

[Hint: Lil is more covalent. According to Fajan's rule, Li+ will be able to polarise the bigger ion, I, more than the smaller ion, F-. More polarisation brings more covalent character.]

- 11. Give one test each to make distinction between the following pairs:
  - (i) NH<sub>4</sub>Cl and KCl
- (ii) Na<sub>2</sub>SO<sub>3</sub> and Na<sub>2</sub>SO<sub>4</sub>
- (iii) Na<sub>2</sub>SO<sub>3</sub> and Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> (iv) KNO<sub>3</sub> and KI
- (v) Na<sub>2</sub>SO<sub>3</sub> and Na<sub>2</sub>CO<sub>3</sub> (vi) NaCl and KCl
- 12. Arrange the following as specified:
  - (i) MgO, SrO, K2O, NiO and Cs2O (increasing order of basic character) [I.I.T. 1991]
  - (ii) LiCl, LiBr and LiI (decreasing order of covalent character)
  - (iii) KCl, KBr and KI (decreasing solubility in water)
  - (iv) NaHCO<sub>3</sub>, KHCO<sub>3</sub>, Mg(HCO<sub>3</sub>)<sub>2</sub> and Ca(HCO<sub>3</sub>)<sub>2</sub> (increasing solubility)
  - (v) LiF, NaF, KF, RbF and CsF (in order of increasing lattice
  - (vi) Li, Na and K (in order of decreasing reducing nature in solution)
- 13. Identify (A), (B), (C) and (D) and give their chemical formulae.

$$(A) + \text{NaOH} \xrightarrow{\text{Heat}} \text{NaCl} + \text{NH}_3 + \text{H}_2\text{O}$$

$$\text{NH}_3 + \text{CO}_2 + \text{H}_2\text{O} \longrightarrow (B)$$

$$(B) + \text{NaCl} \longrightarrow (C) + \text{NH}_4\text{Cl}$$

$$(C) \longrightarrow \text{Na}_2\text{CO}_3 + \text{H}_2\text{O} + (D)$$

14. From the reactions given below, identify (A), (B), (C) and (D)and give their formulae.

$$(A)_{(aq.)} + \operatorname{Zn} \longrightarrow (B)_{\operatorname{gas}}$$

$$(A)_{(aq.)} + (C) \xrightarrow{\operatorname{Heat}} \operatorname{PH}_{3}$$

$$(A)_{(aq.)} + \operatorname{NH}_{4}\operatorname{Cl} \longrightarrow (D)_{\operatorname{gas}}$$

- 15. A certain compound (X) imparts a golden yellow flame and shows the following reactions:
  - (i) Zinc powder when boiled with a concentrated solution of (X) dissolves and hydrogen is evolved.
  - (ii) When an aqueous solution of (X) is added to an aqueous solution of stannous chloride, a white precipitate is obtained first which dissolves in excess of solution of (X).

Identify (X) and write equations for reactions at steps (i) and (ii). [Roorkee 1991]

- **16.** A certain compound (X) is used in the laboratory for analysis, its aqueous solution gives the following reactions:
  - (i) On addition to copper sulphate, a brown precipitate is obtained which turns white on addition of excess of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> solution.

(ii) On addition of Ag+ ion solution, a yellow curdy precipitate is obtained which is insoluble in ammonium hydroxide.

Identify (X) and give equations for the reactions at steps (i)and (ii). [Roorkee 1991]

- 17. An unknown inorganic compound (X) loses its water of crystallization on heating and its aqueous solution gives the following reactions:
  - (a) It gives a white turbidity with dilute HCl solution.
  - (b) It decolourises a solution of iodine in potassium iodide.
  - (c) It gives a white precipitate with silver nitrate solution which turns black on standing.

Identify the compound (X) and give chemical equations for the reactions at steps (a), (b) and (c).

- 18. When 20.02 g of a white solid X is heated, 4.4 g of an acid gas (A) and 1.8 g of a neutral gas (B) are evolved, leaving behind a solid residue (Y) of weight 13.8 g. (A) turns lime water milky and (B) condenses into liquid which changes anhydrous copper sulphate blue. The aqueous solution-of (Y) is alkaline to litmus and gives 19.7 g white precipitate (Z)with barium chloride solution. (Z) gives carbon dioxide with an acid. Identify A, B, X, Y and Z.
- 19. When 16.78 g of a white solid X were heated, 4.4 g of acid gas A that turned lime water milky was driven off together with 1.8 g of a gas B which condensed to a colourless liquid. The solid that remained, Y, dissolved in water to give an alkaline solution, which with excess of barium chloride solution gave a white precipitate, Z. The precipitate effervesced with acid giving off carbon dioxide. Identify A, B and Y and write down the equation for the thermal decomposition of X.
- Gradual addition of potassium iodide solution to Bi(NO<sub>3</sub>)<sub>3</sub> solution initially produces a dark brown precipitate which dissolves in excess of KI to give a clear yellow solution. Write the chemical equations for the above reactions. [L.I.T. 1996]

## Answers: Subjective Type Questions

- (a) Table salt contains impurities such as Na<sub>2</sub>SO<sub>4</sub>, CaSO<sub>4</sub>, MgCl<sub>2</sub> and CaCl<sub>2</sub>. These being hygroscopic absorb moisture from atmosphere. As a result, table salt gets wet.
  - (b) The melting point of sodium is higher as it has greater metallic bonding than potassium.
  - (c) Caesium has low ionisation enthalpy in comparison to lithium. Caesium can lose electrons very easily.
  - (d) Lithium shows different properties than other alkali metals due to following reasons:
    - (i) small atomic and ionic size
    - (ii) high ionisation potential
    - (iii) high polarizing power
- (a) Li<sup>+</sup> ion, being small in size, has high polarising power and hence LiCl is a covalent compound and thus, it is soluble in alcohol.
  - (b) Mg<sup>2+</sup> ion, on account of higher charge than Na<sup>+</sup> ion, has greater polarising power. Hence, MgCl<sub>2</sub> is more covalent than NaCl.
  - (c) Br ion, on account of bigger size than F ion, is more polarisable than F ion. Hence, LiBr is more covalent than LiF and thus, it has lower melting point.
- 3. (a) K, Rb, Cs (b) KF (c) Al(OH)<sub>3</sub> (d) Fr (e) Li (f) Li
- (a) sodium (b) sodium chloride (c) Lepidolite (silicate ore),
   Triphylite (phosphate ore) (d) (i) KOH (ii) Na<sub>2</sub>CO<sub>3</sub>
   (iii) NaNO<sub>3</sub> (e) NaHCO<sub>3</sub>
- 5. (i) Black ash is impure sodium carbonate produced in Le-Blanc method when salt cake is reduced by coke. (ii) Ammonia is liberated: NH<sub>4</sub>Cl + NaOH NH<sub>3</sub> + NaCl + H<sub>2</sub>O (iii) Fused sodium hydroxide. (iv) Sodium carbonate decahydrate. (v) Sodium chloride solution. (vi) Sodium bicarbonate. (vii) Sodium. (viii) Lithium chloride. (ix) Calcium chloride. (x) Sodium formate.
- **6.** (i)  $2KNO_3 \longrightarrow 2KNO_2 + O_2$ 
  - (ii) Water of crystallisation is lost and the substance becomes anhydrous,

- (viii)  $4Na_2S_2O_3 \longrightarrow 3Na_2SO_4 + Na_2S_5$
- 7. (a)  $6\text{NaOH} + 3\text{I}_2 \longrightarrow 5\text{NaI} + \text{NaIO}_3 + 3\text{H}_2\text{O}$ 
  - (b)  $P_4 + 3NaOH + 3H_2O \longrightarrow 3NaH_2PO_2 + PH_3$
  - (c)  $2AgNO_3 + Na_2S_2O_3 \longrightarrow Ag_2S_2O_3 + 2NaNO_3$  $Ag_2S_2O_3 + H_2O \longrightarrow Ag_2S + H_2SO_4$
  - (d)  $I_2 + 2Na_2S_2O_3 \longrightarrow 2NaI + Na_2S_4O_6$
  - (e)  $ZnSO_4 + 2NaOH \longrightarrow Zn(OH)_2 + Na_2SO_4$
  - $Zn(OH)_2 + 2NaOH \longrightarrow Na_2ZnO_2 + 2H_2O$
  - (f)  $AlCl_3 + 3NaOH \longrightarrow Al(OH)_3 + 3NaCl$
  - $Al(OH)_3 + NaOH \longrightarrow NaAlO_2 + 2H_2O$
  - (g)  $2KNO_3 + 10K \longrightarrow 6K_2O + N_2$
  - (h)  $CuSO_4 + 2KI \longrightarrow CuI_2 + K_2SO_4$  $2CuI_2 \longrightarrow Cu_2I_2 + I_2$

(i) 
$$\text{CuSO}_4 + \text{Na}_2\text{S}_2\text{O}_3 \longrightarrow \text{CuS}_2\text{O}_3 + \text{Na}_2\text{SO}_4$$
  
 $2\text{CuS}_2\text{O}_3 + \text{Na}_2\text{S}_2\text{O}_3 \longrightarrow \text{Cu}_2\text{S}_2\text{O}_3 + \text{Na}_2\text{S}_4\text{O}_6$   
 $3\text{Cu}_2\text{S}_2\text{O}_3 + 2\text{Na}_2\text{S}_2\text{O}_3 \longrightarrow \text{Na}_4[\text{Cu}_6(\text{S}_2\text{O}_3)_5]$ 

$$\begin{array}{ccc} \text{(j)} & & 2\text{Na} + \text{O}_2 \xrightarrow{\text{Heat}} \text{Na}_2\text{O}_2 \\ & & \text{Na}_2\text{O}_2 + \text{H}_2\text{SO}_4 \longrightarrow \text{Na}_2\text{SO}_4 + \text{H}_2\text{O}_2 \end{array}$$

8. (i) 
$$4KO_2 + 2H_2O \longrightarrow 4KOH + 3O_2$$

(ii) 
$$2\text{NaNH}_2 + C \xrightarrow{\text{Heat}} \text{Na}_2\text{CN}_2 + 2\text{H}_2 \uparrow$$
  $\text{Na}_2\text{CN}_2 + C \longrightarrow 2\text{NaCN}$ 

- (iii)  $PbO_2 + 2NaOH \longrightarrow Na_2PbO_3 + H_2O$
- (iv)  $2KI + H_2SO_4 + H_2O_2 \longrightarrow I_2 + K_2SO_4 + 2H_2O_4$
- (v)  $6\text{NaOH} + 3\text{I}_2 \longrightarrow 5\text{NaI} + \text{NaIO}_3 + 3\text{H}_2\text{O}$
- 9. (a) See properties of NaOH.
  - (b) See properties of sodium thiosulphate.
- 11. (a) When heated with NaOH, NH<sub>4</sub>Cl evolves ammonia gas.

$$NH_4Cl + NaOH \longrightarrow NH_3 + NaCl + H_2O$$

(b) On treatment with dil. H<sub>2</sub>SO<sub>4</sub>, a pungent gas, SO<sub>2</sub>, is evolved which turns acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> green.

$$Na_2SO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O + SO_2$$

(c) On addition of AgNO<sub>3</sub> solution, sodium thiosulphate gives a white precipitate which turns black.

$$2AgNO_3 + Na_2S_2O_3 \longrightarrow Ag_2S_2O_3 + 2NaNO_3$$
  
 $Ag_2S_2O_3 + H_2O \longrightarrow Ag_2S + H_2SO_4$ 

(d) On addition of AgNO<sub>3</sub> solution, KI gives a yellow precipitate of AgI.

$$2AgNO_3 + 2KI \longrightarrow 2AgI + 2KNO_3$$

- (e) On addition of dil. HCl, Na<sub>2</sub>SO<sub>3</sub> gives pungent gas which turns acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> paper green.
- (f) Flame test.
- 12. (i) NiO < MgO < SrO <  $K_2O$  <  $Cs_2O$ 
  - (ii) LiI > LiBr > LiCl
  - (iii) KI > KBr > KCl, lattice energy of KI is lower than the lattice energy of KCl.
  - (iv)  $NaHCO_3 < KHCO_3 < Mg(HCO_3)_2 < Ca(HCO_3)_2$
  - (v) CsF < RbF < KF < NaF < LiF
  - (vi) Li > K > Na
- 13. (A) NH<sub>4</sub>Cl, ammonium chloride; (B) NH<sub>4</sub>HCO<sub>3</sub>, ammonium bicarbonate; (C) NaHCO<sub>3</sub>, sodium bicarbonate; (D) CO<sub>2</sub>, carbon dioxide.
- 14. (A) NaOH, sodium hydroxide; (B) H<sub>2</sub>, hydrogen; (C) P<sub>4</sub>, phosphorus; (D) NH<sub>3</sub>, ammonia.
- 15. (X) = NaOH

(i) 
$$Zn + 2NaOH \longrightarrow Na_2ZnO_2 + H_2$$
  
(ii)  $SnCl_2 + 2NaOH \longrightarrow Sn(OH)_2 + 2NaCl$   
 $Sn(OH)_2 + 2NaOH \longrightarrow Na_2SnO_2 + 2H_2O$ 

Soluble

16. 
$$X = KI$$
  
(i)  $2CuSO_4 + 4KI \longrightarrow 2CuI_2 + 2K_2SO_4$   
 $2CuI_2 \longrightarrow Cu_2I_2 + I_2$   
(White)  $I_2 + 2Na_2S_2O_3 \longrightarrow 2NaI + Na_2S_4O_6$   
(ii)  $Ag^+ + KI \longrightarrow AgI + K^+$   
Yellow ppt.  
Insoluble in NH<sub>4</sub>OH

17.  $X = Na_2S_2O_3.5H_2O$ .

(a) 
$$Na_2S_2O_3 + 2HCl \longrightarrow 2NaCl + H_2O + S + SO_2$$

(b) 
$$KI_3 + 2Na_2S_2O_3 \longrightarrow KI + 2NaI + Na_2S_4O_6$$

(c) 
$$2AgNO_3 + Na_2S_2O_3 \longrightarrow Ag_2S_2O_3 + 2NaNO_3$$
  
 $Ag_2S_2O_3 + H_2O \longrightarrow Ag_2S + H_2SO_4$ 

18. 
$$(X)$$

White solid

Acid gas

Neutral gas

Residue

20.02 g

4.4 g

1.8 g

13.8 g

H<sub>2</sub>O

Anhydrous

CuSO<sub>4</sub>

Alkaline to litmus

CuSO<sub>4</sub>·5H<sub>2</sub>O (Blue)

 $\downarrow$  BaCl<sub>2</sub> soln. White ppt. (Z) 19.7 g

 $CO_2 \stackrel{Acid}{\longleftarrow}$ 

(Z) is a carbonate as it evolves  $CO_2$  with acid. (Y) is also a carbonate of an alkali metal because its solution is alkaline to litmus and gives a white precipitate of  $BaCO_3$  with  $BaCl_2$  soln. (B) is  $H_2O$  and (A) is  $CO_2$ . Thus, (X) is a bicarbonate, MHCO<sub>3</sub>.

$$2MHCO_3 \longrightarrow CO_2 + H_2O + M_2CO_3$$

$$(X) \qquad (A) \qquad (B) \qquad (Y)$$

$$2[X + 61]$$

44 g  $CO_2$  is obtained from 2(X + 61) g of X

4.4 g CO<sub>2</sub> is obtained from 
$$\frac{2(X + 61)}{44} \times 4.4 = \frac{X + 61}{5}$$
 g of X

So, 
$$\frac{X+61}{5} = 20.02$$
 or  $X = 39.1$  g

Therefore, the alkali metal is K.

Thus, X is KHCO<sub>3</sub>

$$2KHCO_3 \longrightarrow K_2CO_3 + CO_2 + H_2O \\ (X) \qquad (Y) \qquad (A) \qquad (B)$$
 
$$K_2CO_3 + BaCl_2 \longrightarrow BaCO_3 + 2KCl$$

138.2 g of K<sub>2</sub>CO<sub>3</sub> forms 197 g BaCO<sub>3</sub>

13.8 g of  $K_2CO_3$  forms  $\frac{197}{138.2} \times 13.8$  g BaCO $_3$  or 19.7 g

This confirms the given data.

19. X is NaHCO<sub>3</sub>.

20. At first, Bi(NO<sub>3</sub>)<sub>3</sub> undergoes hydrolysis. Nitric acid is formed. Which oxidises KI to iodine. The liberated iodine dissolves in KI to form yellow solution of KI<sub>3</sub>.

$$\begin{array}{c} \text{Bi}(\text{NO}_3)_3 \ + \ \text{H}_2\text{O} \longrightarrow [\text{Bi}(\text{OH})(\text{NO}_3)_2] \ + \ \text{HNO}_3 \\ \\ 2\text{HNO}_3 \longrightarrow \text{H}_2\text{O} \ + \ 2\text{NO}_2 \ + \ \text{O} \\ \\ 2\text{KI} \ + \ \text{H}_2\text{O} \ + \ \text{O} \longrightarrow 2\text{KOH} \quad + \quad \text{I}_2 \\ \\ \text{Dark brown} \\ \\ \text{I}_2 \ + \ \text{KI} \longrightarrow \qquad \text{KI}_3 \\ \text{Yellow solution} \end{array}$$

Answers: Matching Type Questions

- [A] (a—viii); (b—vi); (c—i); (d—vii); (e—ii); (f—iv); (g—iii); (h—v);
- [B] (a—v); (b—viii); (c—vii); (d—vi); (e—ii); (f—iii); (g—iv); (h—i)

## ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. Which one of the following statements is true for all the alkali metals?
  - (a) Their nitrates decompose on heating to give  $NO_2$  and  $O_2$ .
  - (b) Their carbonates decompose on heating to give CO<sub>2</sub> and normal oxide.
  - (c) They react with halogens to give the halides of the type, MX.
  - (d) They react with oxygen to give mainly the oxide,  $M_2$ O. Ans. (c)
- 2. The electrolyte used in Castner's process of sodium extraction is:
  - (a) anhydrous Na<sub>2</sub>CO<sub>3</sub>
- (b) aqueous NaOH
- (c) NaCl + CaCl<sub>2</sub>
- (d) fused anhydrous NaOH

Ans. (d)

- 3. Based on lattice energy and other considerations which one of the following alkali metal chloride is expected to have highest melting point?
  - (a) LiCl

(b) NaCl

(c) KCl

(d) RbCl

Ans. (b)

[Hint: On the basis of lattice energy, the melting point decreases in the alkali group as lattice energy decreases with the

increase of the atomic number. However, LiCl has covalent character due to very small size of Li<sup>+</sup> ion. Hence, melting point of NaCl is highest amongst the above chlorides.]

- 4. Select correct statement:
  - (a) Oxides  $(M_2O)$  and peroxides  $(M_2O_2)$  of alkali metals are diamagnetic and colourless.
  - (b) Superoxides  $(MO_2)$  of alkali metals are paramagnetic.
  - (c) Li and Na do not form superoxides.
  - (d) All are correct.

Ans. (d)

- 5. Which of the following salts does not form any precipitate with excess of NaOH?
  - (a) ZnCl<sub>2</sub>
- (b) FeCl<sub>3</sub>
- (c) CrCl<sub>3</sub>
- (d) CuSO<sub>4</sub>

Ans. (a)  $[\text{Hint}: ZnCl_2 + NaOH \longrightarrow Zn(OH)_2 \xrightarrow{\text{NaOH}} Na_2ZnO_2$ Soluble

 $FeCl_3 + NaOH \longrightarrow Fe(OH)_3$  (brown ppt.)

 $CrCl_3 + NaOH \longrightarrow Cr(OH)_3$  (green ppt.)

 $CuSO_4 + NaOH \longrightarrow Cu(OH)_2$  (blue ppt.)]

**6.** Which of the following is best CO<sub>2</sub> absorber as well as source of O<sub>2</sub> in space capsule?

(a)	$KO_2$
(c)	KOH
An	s. (a)

(b)  $K_2O_2$ 

(d) LiOH

[Hint:  $4KO_2 + 2CO_2 \longrightarrow 2K_2CO_3 + 3O_2$ ]

Match the compounds given in (X) with their uses in (Y).

(Y)

- A. NaOH
- Glass 1.
- B. Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>
- 2. Germicide
- C. NaCN
- 3. Antichlor

D. Na<sub>2</sub>CO<sub>3</sub>

Soap

## Codes:

	Α	В	C	D
(a)	4	3	2	1
(b)	3	4	- 1	2
(c)	2	3	4	. 1
(d)	1	2	3	4

- Ans. (a)
- 8. On dissolving moderate amount of sodium metal in liquid ammonia at low temperature, which of the following does not occur?
  - (a) Blue coloured solution is obtained
  - (b) Na<sup>+</sup> ions are formed in solution
  - (c) Liquid ammonia becomes good conductor of electricity
  - (d) The liquid ammonia remains diamagnetic Ans. (d)
- The aqueous solutions of lithium salts are poor conductor of electricity rather than other alkali metals because of:
  - (a) high ionisation energy
  - (b) high electronegativity
  - (c) lower ability of Li<sup>+</sup> ions to polarise water molecules
  - (d) higher degree of hydration of Li<sup>+</sup> ions Ans. (d)
- 10. NaOH + CO $\xrightarrow{200^{\circ}\text{C}} X$ . The product X is :
  - (a) NaHCO<sub>3</sub>
- (b) Na<sub>2</sub>CO<sub>3</sub>
- (c) HCOONa
- (d)  $H_2CO_3$

- Ans. (c)
- 11. Which of the property of alkali metals is not listed correctly?
  - (a) The least electronegative metal: Cs
  - (b) A natural radioactive metal: Fr
  - (c) The alkali metal with lowest density: K
  - (d) The most abundant alkali metal in earth's crust : Na Ans. (c)

- 12. Which among the following is least soluble in water?
  - (a) NaF

(b) LiF

(c) KF

(d) RbF

Ans. (b)

[Hint: LiF has maximum lattice energy and hence least soluble.]

- 13. Which of the following metals is used for drying organic solvents?
  - (a) Magnesium
- (b) Sodium
- (c) Platinum
- (d) Nickel

Ans. (b)

- 14. Which of the following does not illustrate the anomalous behaviour of lithium?
  - (a) Lithium reacts with nitrogen to form a nitride
  - (b) Lithium is the hardest alkali metal
  - (c) Lithium reacts with oxygen to form normal oxide only
  - (d) Lithium carbonate decomposes on heating Ans. (b)
- 15. The correct order of stability of hydrides of alkali metals is:
  - (a) LiH > NaH > KH > RbH (b) NaH > KH > RbH > LiH
  - (c) RbH > KH > NaH > LiH (d) LiH > RbH > KH > NaH Ans : (a)

[Hint: Small anion forms stable compound with small cation.]

- 16. The correct order of mobility of alkali metal ions in aqueous solution is: [C.B.S.E. 2006]
  - (a)  $K^+ > Rb^+ > Na^+ > Li^+$
- (b)  $Rb^+ > K^+ > Na^+ > Li^+$
- (c)  $Li^+ > Na^+ > K^+ > Rb^+$
- (d)  $Na^+ > K^+ > Rb^+ > Li^+$

Ans : (b)

[Hint: Smaller the size of the ion, more is the hydration and therefore lesser is the mobility.]

- 17. Pick out statement(s) which is(are) not true about diagonal relationship of Li and Mg:
  - A Polarising powers of Li<sup>+</sup> and Mg<sup>2+</sup> ions are almost same
  - B Like Li, Mg decomposes water very fast
  - C LiCl and MgCl<sub>2</sub> are deliquescent
  - D Like Li, Mg readily reacts with liquid bromine at ordinary temperature
  - (a) A and D
- (b) B and C
- (c) Only B Ans : (d)
- (d) B and D

# **OBJECTIVE QUESTIONS**

12.				25.	An element having elec	tronic	c configuration $1s^2$ , $2s^2$	$2p^{6}$ ,
	due to the presence of:		U		$3s^2 3p^6$ , $4s^1$ will form:		-	_
	(a) sodium atoms	(b) sodium hydride			(a) acidic oxide		(b) basic oxide	
	(c) sodium amide	(d) solvated electrons			(c) amphoteric oxide		(d) neutral oxide	
					=			

26.	The products of electrolysis of concentrated common solution are:	salt	38.	Na <sub>2</sub> CO <sub>3</sub> + Fe <sub>2</sub> O <sub>3</sub> $\longrightarrow$ A + CO <sub>2</sub> , what is A in the reaction? (a) NaFeO <sub>2</sub> $\square$ (b) Na <sub>3</sub> FeO <sub>3</sub> $\square$
				(c) $Fe_3O_4$
	(a) $Na + Cl_2$		20	· / 2 2
	(c) NaOH + $H_2$ + $Cl_2$ $\Box$ (d) NaOH + $Cl_2$ + $O_2$		39.	When dry ammonia gas is passed over heated sodium (out
27.	Elements in the first column of the periodic table are c	alled		of contact of air) the product formed is:
	alkali metals. These metals have:	* .		(a) sodium hydride
	(a) a single valency electron			(c) sodamide $\Box$ (d) sodium cynamide $\Box$
	(b) one electron less than an inert gas configuration		40.	The name oxone is given to:
	(c) high melting points			(a) ozone $\Box$ (b) sodium peroxide $\Box$
	(d) high ionisation potentials			(c) sodium oxide $\Box$ (d) sodamide $\Box$
28.	One of the natural minerals of sodium is tincal. Its for	mula	41.	The principal products obtained on heating iodine with
	is:			concentrated caustic soda solution:
	(a) Na <sub>2</sub> CO <sub>3</sub> ·10H <sub>2</sub> O			(a) NaIO + NaI
	(c) $Na_2B_4O_7:10H_2O$ $\square$ (d) $NaCl$			(c) $NaIO_3 + NaI$ $\square$ (d) $NaIO_4 + NaI$ $\square$
29	Potassium when heated strongly in oxygen, it forms:	_	42.	When a concentrated solution of ammonia is saturated with
2).	(a) $K_2O$ $\Box$ (b) $KO_2$			sodium chloride in the presence of pieces of dry ice, a water
	(c) $K_2O_2$ $\square$ (d) $KO_2$			cloud is formed. This is due to :
20	*			(a) precipitation of sodium hydrogen carbonate from the
30.	The reaction of sodium is highly exothermic with water	. 1116		reaction mixture
	rate of reaction is lowered by:			(b) precipitation of ammonium carbonate
	(a) lowering the temperature			(c) precipitation of ammonium hydrogen carbonate from the
	(b) mixing with alcohol			
	(c) mixing with acetic acid			reaction mixture
	(d) making an amalgam			(d) precipitation of sodium carbonate from the reaction
31.	What product is obtained after electrolysis in Solvay tr	rough		mixture
	cell ?			[Hint: $NH_3 + H_2O + CO_2$ (dry ice) $\longrightarrow NH_4HCO_3$
	(a) NaOH			$NaCl + NH_4HCO_3 \longrightarrow NaHCO_3 + NH_4Cl]$
	(c) Na $\Box$ (d) Na <sub>2</sub> CO <sub>3</sub>		43.	A combustible gas is liberated when caustic soda solution
32.	RbO <sub>2</sub> is:			is heated with:
	(a) superoxide and paramagnetic	· 🗆		(a) S $\square$ (b) NH <sub>4</sub> Cl $\square$
•	(b) superoxide and diamagnetic			(c) $I_2$ $\square$ (d) $Z_n$
	(c) peroxide and paramagnetic		44.	Caustic soda is:
	(d) peroxide and diamagnetic			(a) efflorescent $\Box$ (b) deliquescent $\Box$
33.	KOH is preferably used to absorb CO <sub>2</sub> gas because:	`		(c) hygroscopic $\Box$ (d) oxidant $\Box$
	(a) KHCO <sub>3</sub> is soluble in water while NaHCO <sub>3</sub> is spar	ringly	45.	When ammonical common salt solution is saturated with
	soluble in water	Ő		carbon dioxide we obtain:
	(b) KOH is cheaper than NaOH			(a) $NH_4HCO_3$
	(c) KOH is stronger base than NaOH			(c) NaHCO <sub>3</sub>
	(d) KOH is more soluble than NaOH in water		46.	The compound called microcosmic salt is:
34.	What are the raw materials used in Solvay process?	-		(a) $Na_2HPO_4\cdot 2H_2O$ $\square$ (b) $Na(NH_4)HPO_4\cdot 4H_2O$ $\square$
51.	(a) NaCl, NH <sub>3</sub> , CaCO <sub>3</sub>			(c) $Na_2NH_4PO_4\cdot 2H_2O$ $\square$ (d) $(NH_4)_2HPO_4\cdot 2H_2O$ $\square$
	(c) NaCl, $CO_2$		47.	From a solution of zinc chloride, zinc carbonate can be
	(d) NaCl, CaCO <sub>3</sub> , C, H <sub>2</sub> SO <sub>4</sub>		"	obtained by adding:
25		<u></u>		(a) NaHCO <sub>3</sub>
35.	The solubility of iodine in water is increased by:	П		(c) $CaCO_3$
	(a) boiling the solution		48.	Sodium carbonate solution is alkaline due to:
	(b) cooling the solution		70.	(a) hydrolysis of Na <sup>+</sup>
	(c) adding acid			
	(d) adding potassium iodide			(-))
36.	Potassium nitrate is called:			(c) hydrolysis of both Na <sup>+</sup> and CO <sub>3</sub> <sup>-</sup> ions
	(a) Mohr's salt $\square$ (b) Indian saltpetre			(d) none of the above
	(c) Gypsum		49.	When chlorine is passed through concentrated solution o
37.	In the following reaction,			KOH, the compound formed is:
	$NaOH + S \longrightarrow A + Na_2S_5 + H_2O$ ,			(a) KClO
	A is:			(c) $KClO_3$
	(a) $Na_2SO_3$ $\square$ (b) $Na_2SO_4$		50.	If NaOH is added to an aqueous solution of Zn <sup>2+</sup> ions,
	(c) $Na_2S_2O_3$ $\square$ (d) $Na_2S$			white precipitate appears and on adding excess of NaOH

	the precipitate dissolves. In the solution, zinc exists in the:	62.	A white solid reacts with dil. HCl to give colourless gas to decolourises aqueous bromine. The solid is most likely	
	(a) anionic part		be:	Ю
	(b) cationic part		(a) sodium carbonate	
	(c) both in anionic and cationic parts		• •	
	(d) colloidal form	63	In the following sequence of reactions, identify	
51.	Which of the following has lowest thermal stability?	05.	compounds $(A)$ , $(B)$ , $(C)$ and $(D)$ :	u.c
J1.	(a) Li <sub>2</sub> CO <sub>3</sub>		SO <sub>2</sub> Na <sub>2</sub> CO <sub>3</sub> S AgNO <sub>3</sub>	
	(c) $K_2CO_3$ $\square$ (d) $Rb_2CO_3$ $\square$	. '	$Na_2CO_3 \xrightarrow{SO_2} (A) \xrightarrow{Na_2CO_3} (B) \xrightarrow{S} (C) \xrightarrow{AgNO_3} (A)$	D)
52.	Which salt on heating does not give brown coloured gas?		Solution (a) No SQ, NoUSQ, No S, A C S	
	(a) LiNO <sub>3</sub>		(a) Na <sub>2</sub> SO <sub>3</sub> , NaHSO <sub>3</sub> , Na <sub>2</sub> S, Ag <sub>2</sub> S	
	(c) $Pb(NO_3)_2$ $\square$ (d) $AgNO_3$ $\square$		(b) NaHSO <sub>3</sub> , Na <sub>2</sub> SO <sub>3</sub> , Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub> , Ag <sub>2</sub> S (c) NaHSO <sub>3</sub> , Na <sub>2</sub> SO <sub>4</sub> , Na <sub>2</sub> S, Ag <sub>2</sub> O	
53.	Fire extinguishers contain H <sub>2</sub> SO <sub>4</sub> and:			
	(a) NaHCO <sub>3</sub> and Na <sub>2</sub> CO <sub>3</sub> □ (b) NaHCO <sub>3</sub> solution □		(d) Na <sub>2</sub> SO <sub>3</sub> , Na <sub>2</sub> SO <sub>4</sub> , Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub> , Ag	ш
	(c) Na <sub>2</sub> CO <sub>3</sub>		[Hint: $Na_2CO_3 + 2SO_2 + H_2O \longrightarrow 2NaHSO_3 + CO_2$	
54.	Which of the following compound is used in gun powder?		$2\text{NaHSO}_3 + \text{Na}_2\text{CO}_3 \longrightarrow 2\text{Na}_2\text{SO}_3 + \text{H}_2\text{O} + \text{CO}_2$	
	(a) $LiNO_3$ $\Box$ (b) $NaNO_3$ $\Box$		(B)	
	(c) $Pb(NO_3)_2$ $\square$ (d) $KNO_3$ $\square$		$Na_2SO_3 + S \longrightarrow Na_2S_2O_3$	
55.	Which of the following compounds is(are) not soluble in		(C)	
	water?		$Na_2S_2O_3 + 2AgNO_3 \longrightarrow Ag_2S_2O_3 + 2NaNO_3$	
	(a) $\text{Li}_2\text{CO}_3$ $\square$ (b) $\text{Li}_7$		$Ag_2S_2O_3 + H_2O \longrightarrow Ag_2S + H_2SO_4$	
	(c) Li <sub>3</sub> PO <sub>4</sub>		(D)	
56.	When a standard solution of NaOH is left in air for a few	64	$ZnCl_2 + NaHCO_3 \xrightarrow{\text{Heat}} (A) \xrightarrow{\text{Heat}} (B) + (C) \uparrow + H_2$	n .
	hours:	04.		
	(a) a precipitate will form		$(B) + \text{NaOH} \longrightarrow D$	
	(b) strength will decrease □		Identify the compound $D$ present in the solution :	
	(c) strength will increase		(a) $ZnCO_3$ $\Box$ (b) $Zn(OH)_2$	
	(d) the concentration of $Na^+$ ions will remain constant $\square$		(c) ZnO $\square$ (d) Na <sub>2</sub> ZnO <sub>2</sub>	
57.	The pair of compounds which cannot exist together in		[Hint: $ZnCl_2 + 2NaHCO_3 \longrightarrow Zn(HCO_3)_2 + 2NaCl$	
	solution is:		$Zn(HCO_3)_2 \longrightarrow ZnCO_3 + H_2O + CO_2$ (B) (C)	
	(a) NaHCO <sub>3</sub> and NaOH $\Box$ (b) Na <sub>2</sub> CO <sub>3</sub> and NaHCO <sub>3</sub> $\Box$		$(B) \qquad \qquad (C)$	
	(c) $Na_2CO_3$ and $NaOH$ $\square$ (d) $NaHCO_3$ and $NaCl$ $\square$		$ZnCO_3 + 2NaOH \longrightarrow Zn(OH)_2 + Na_2CO_3$	
58.	Which of the following reaction/s is/are correct?			
	(i) $Cl_2 + NaOH \longrightarrow NaCl + NaClO_2 + H_2O$		$Zn(OH)_2 + 2NaOH \longrightarrow Na_2ZnO_2 + 2H_2O$ ]	
	(i) $Cl_2 + NaOH \longrightarrow NaCl + NaClO_3 + H_2O$ Conc. and hot	65.	LiAlH <sub>4</sub> is used as:	
	solution (ii) $P_4 + NaOH + H_2O \longrightarrow NaH_2PO_2 + PH_3$		(a) an oxidising agent	
	(ii) $P_4 + NaOH + H_2O \longrightarrow NaH_2PO_2 + PH_3$ (yellow)		(c) a mordant	
	(iii) $S + NaOH \xrightarrow{\text{Heat}} Na_2S_2O_3 + Na_2S + H_2O$	66.	Sodium sulphate is soluble in water whereas barium sulph	ate
	(m) 5 + NaO11		is sparingly soluble because:	
	(iv) $C + NaOH \xrightarrow{Heat} Na_2SiO_3 + H_2$		(a) the hydration energy of sodium sulphate is more that	han
	(a) (i) and (ii) $\square$ (b) (ii) and (iii) $\square$		its lattice energy	
	(c) (i), (ii) and (iii) $\Box$ (d) all are correct $\Box$		(b) the lattice energy of barium sulphate is less than	its
59.	The most abundant alkali metal in nature is:		hydration energy	
٥).	(a) lithium		(c) the lattice energy has no role to play is solubility	
	(c) potassium		(d) the hydration energy of sodium sulphate is less than	its
60.	When sodium hydroxide solution is electrolysed:		lattice energy	U ·
	(a) hydrogen is discharged at cathode □	67.	e e	mic
	(b) hydrogen is discharged at anode □	İ	number of alkali metals increases?	_
	(c) sodium is liberated at anode		(a) Electronegativity	닏
	(d) no hydrogen is liberated		(b) First ionisation potential	닏
61.	In the Castner process for the extraction of sodium, the anode		(c) Ionic radius	니
	is made of : [E.A.M.C.E.T. 2003]	60	(d) Melting point	
	(a) nickel	68.	, L	_
	(c) copper		(a) less electronegativity	
			(b) more ionisation potential	ш

	(c) larger atomic radius		83.	Thermal stability of hydrides of first group elements follows
	(d) lower melting point			the order: [C.B.S.E. 2008]
69.	Which of the following alkali metals does not form alun	ns?		(a) LiH > NaH > KH $\rightarrow$ RbH
	(a) Rb			(b) LiH > KH > NaH > RbH
	(c) Na			(c) LiH > RbH > KH > NaH
70.	Incorrect match is:	_		(d) LiH > KH > RbH > NaH
70.			84.	There occurs loss of mass when a mixture of Li <sub>2</sub> CO <sub>3</sub> and
	(a) Soda ash: $Na_2CO_3$			Na <sub>2</sub> CO <sub>3</sub> ·10H <sub>2</sub> O is heated strongly. The loss of mass is due
	(c) Pearl ash: $K_2CO_3$ $\square$ (d) Baking soda: NaHCC	-		to:
71.	The metallic lustre exhibited by sodium is explained by:			(a) decomposition of Li <sub>2</sub> CO <sub>3</sub> only
	(a) diffusion of sodium ions			(b) loss of water by Na <sub>2</sub> CO <sub>3</sub> ·10H <sub>2</sub> O
	(b) oscillation of mobile valence electrons			(c) both (a) and (b)
	(c) existence of free protons			(d) none of these
	(d) existence of body centred cubic lattice		95	In certain matters, lithium differs from other alkali metals, the
72.	Crude common salt is hygroscopic because of impurities	of:	65.	main reason for this is:
	(a) CaSO <sub>4</sub> and MgSO <sub>4</sub>			(a) small size of lithium atom and Li <sup>+</sup>
	(b) CaCl <sub>2</sub> and MgCl <sub>2</sub>			
	(c) CaBr <sub>2</sub> and MgBr <sub>2</sub>	<u> </u>		(b) extremely high electropositivity of Li
	(d) Ca(HCO <sub>3</sub> ) <sub>2</sub> and Mg(HCO <sub>3</sub> ) <sub>2</sub>	ā		(c) greater hardness of Li (d) hydration of Li <sup>+</sup> ion
73.	Which of the following compounds of potassium is known			(-))
13.	as 'pearl ash'?	JWII	86.	Identify the correct statement. Elemental sodium:
	-			(a) can be prepared and isolated by electrolysing an aqueous
	(a) $K_2CO_3$			solution of sodium chloride
	(c) KCl $\Box$ (d) KNO <sub>3</sub>			(b) is a strong oxidising agent
74.	•	e of		(c) is insoluble in ammonia
	NaOH, the ion discharged at cathode is:			(d) is easily oxidised $\Box$
	(a) $Na^+$		87.	
	(c) $H^+$			(a) Na
75.	When sodium is added in scanty water, it catches fire	. In		(c) K $\square$ (d) Rb $\square$
	this process which one of the following burns?		88.	Which of the following compounds on reaction with NaOH
	(a) Na $\Box$ (b) H <sub>2</sub> O			and H <sub>2</sub> O <sub>2</sub> gives yellow colour?
	(c) CO $\Box$ (d) $H_2$			(a) $Zn(OH)_2$ $\Box$ (b) $Cr(OH)_3$ $\Box$
76.	Among LiCl, RbCl, BeCl <sub>2</sub> and MgCl <sub>2</sub> the compounds	with	İ	(c) $Al(OH)_3$ $\Box$ (d) None of these $\Box$
	greatest and least ionic character respectively are:		89.	The stability of the following alkali metal chlorides follows
	(a) LiCl, RbCl			the order:
	(c) RbCl, MgCl <sub>2</sub> $\square$ (d) MgCl <sub>2</sub> , BeCl <sub>2</sub>			(a) LiCl > KCl > NaCl > CsCl
<i>7</i> 7.	Stable oxide is obtained by heating the carbonate of	_		(b) CsCl > KCl > NaCl > LiCl
,,,	element:	uic		(c) NaCl > KCl > LiCl > CsCl
	(a) Li			(d) KC1 > CsCl > NaCl > LiCl
	(c) K		90.	Which of the following has the highest melting point?
78.	The chloride that can be extracted with ether is:	<b></b>		(a) NaCl
70.				(c) NaBr
	(a) NaCl (b) KCl		91	Oxone is: [P.M.T. (Manipal) 2001]
70	(c) LiCl	<u></u>	71.	(a) CaO $\square$ (b) N <sub>2</sub> O $\square$
79.	Prefix 'alkali' for alkali metals denotes:	_	j	(c) $Na_2O_2$ $\square$ (d) $NaBO_3$ $\square$
	(a) silvery lustre		m	
	(c) active metals		92.	
80.	2 7			[P.M.T. (M.P.) 2002]
	(a) due to small size of lithium			(a) weak oxidising agents
	(b) due to high hydrogen number of lithium			(b) strong reducing agents
	(c) due to high ionisation energy of lithium			(c) strong oxidising agents $\square$
	(d) none of the above			(d) weak reducing agents $\square$
81.	For the preparation of sodium thiosulphate by "Spri	ng's	93.	Which of the following has lowest melting point?
	reaction", the reactants used are: [E.A.M.C.E.T.2	003]		[B.V. (Pune) 2002]
	(a) $Na_2S + Na_2SO_3 + Cl_2 \square$ (b) $Na_2S + SO_2$			(a) Li
	(c) $Na_2S + Na_2SO_3 + I_2$			(c) K
82.			94,	When sodium is treated with sufficient oxygen/air, the
	(a) decreases		77.	product obtained is: [A.F.M.C. 2002]
	(c) remains the same  (d) none of these	П	1	product obtained is. [A.F.W.C. 2002]

## **Objective Questions for IIT ASPIRANTS**

- Zinc on reaction with NaOH gives a salt (A) along with a gas (X) and (A) on reaction with a gas (Y) gives white precipitate (W). Which of the following is correct?
  - (a) (A) is  $Na_4ZnO_3$ , (Y) is  $H_2S$  (b) (X) is  $H_2$ , (W) is Zn (OH)<sub>2</sub> (c) (A) is  $Na_2ZnO_2$ , (X) is  $O_2$  (d) (W) is ZnS, (X) is  $H_2$

$$[\textbf{Hint}: Zn + 2NaOH \longrightarrow Na_2ZnO_2 + H_2 \ ;$$

$$Na_2ZnO_2 + H_2S \longrightarrow ZnS + 2NaOH]$$

$$(Y) \qquad (W)$$

- 2. For Na + NH<sub>3</sub>  $\longrightarrow$  (A)  $\xrightarrow{\text{N}_2\text{O}}$  (B)  $\xrightarrow{\text{Heat}}$  gas (X),
  - Which of the following is correct?
  - (a) (A) on reaction with water gives NaOH and N<sub>2</sub>
  - (b) (B) contains anion of linear geometry
  - (c) (X) is coloured
- (d) All are correct

(c) (X) is coloured (d) All are correct

[Hint: Na + NH<sub>3</sub> 
$$\longrightarrow$$
 NaNH<sub>2</sub>  $\xrightarrow{N_2O}$  NaN<sub>3</sub>  $\longrightarrow$  Na + N<sub>2</sub>
(A) (B) (X)

The anion in (B) is  $N_3^-$  which possesses a linear geometry.

- CO<sub>2</sub> gas along with solid (Y) is obtained when sodium salt (X) is heated. (X) is again obtained when  $CO_2$  gas is passed into aqueous solution of (Y). (X) and (Y) are:
  - (a) Na<sub>2</sub>CO<sub>3</sub>, Na<sub>2</sub>O
- (b) Na<sub>2</sub>CO<sub>3</sub>, NaOH
- (c) NaHCO<sub>3</sub>, Na<sub>2</sub>CO<sub>3</sub>
- (d) Na<sub>2</sub>CO<sub>3</sub>, NaHCO<sub>3</sub>

[Hint: 
$$2NaHCO_3 \xrightarrow{Heat} Na_2CO_3 + H_2O + CO_2$$
;  
 $(X)$   $(Y)$   
 $Na_2CO_3 + H_2O + CO_2 \longrightarrow 2NaHCO_3$ ]  
 $(X)$   $(Y)$ 

- For Na + PH<sub>3</sub>  $\longrightarrow$  (A) + gas(X), Na + NH<sub>3</sub>  $\longrightarrow$  (B) + gas
  - (X), which of the following is correct?
  - (a) The anion of (A) is trinegative while the anion of (B) on reaction with acetylene gives ammonia
  - (b) The anion of both (A) and (B) are uninegative
  - (c) The anion of both (A) and (B) are trinegative
  - (d) None of the above

[Hint: 
$$3\text{Na} + \text{PH}_3 \longrightarrow \text{Na}_3\text{P} + \frac{3}{2}\text{H}_2$$
;  
 $Na + \text{NH}_3 \longrightarrow \text{Na}_2\text{NH}_2 + \frac{1}{2}\text{H}_2$ ;  
 $(B)$ 

$$NaNH_2 + C_2H_2 \longrightarrow NaC_2H + NH_3$$

- 5. Sodium oxide can be obtained by heating:
  - (a) sodium carbonate alone
- (b) sodium nitrate alone
- (c) sodium nitrite with sodium (d) none of these
- [Hint:  $2NaNO_2 + 6Na \longrightarrow 4Na_2O + N_2$ ]
- **6.**  $A + \text{Na}_2\text{CO}_3 \longrightarrow B + C$

 $CO_2$  Milky cloud, C

The chemical formulae of A, B and C are:

$$A \qquad B \qquad C$$

- (a)  $Ca(OH)_2$ CaCO<sub>3</sub> NaOH
- Ca(OH)<sub>2</sub> CaCO<sub>3</sub> (b) NaOH
- (c) NaOH CaO CaCO<sub>3</sub>
- (d) CaO Ca(OH)2 NaOH

[Hint: 
$$Ca(OH)_2 + Na_2CO_3 \longrightarrow 2NaOH + CaCO_3$$

$$(B) \qquad (CO_2) \longrightarrow CaCO_3$$

- 7. An aqueous solution of an halogen salt of potassium reacts with same halogen X to give  $KX_3$ , a violet coloured solution which is used in volumetric exercises (iodimetric titrations). The halogen X is:
  - (a) fluorine
- (b) bromine
- (c) chlorine
- (d) iodine

[**Hint**:  $KI + I_2 \longrightarrow KI_3$  (violet coloured solution)]

- **8.** In LiAlH<sub>4</sub>, metal Al is present in:
  - (a) cationic part
  - (b) anionic part
  - (c) in both cationic and anionic parts
  - (d) neither in cationic nor in anionic part

[Hint: LiAlH<sub>4</sub> 
$$\rightleftharpoons$$
 Li<sup>+</sup> + AlH<sub>4</sub> | Anion

- 9. When sodium reacts with excess of oxygen, oxidation number of oxygen changes from:
  - (a) 0 to -1
- (b) 0 to -2
- (c) -1 to -2
- (d) + 1 to -1

- 10. Sodium is heated in air at 350°C to form X. X absorbs CO<sub>2</sub> and forms sodium carbonate and Y. Which of the following is Y?
  - (a) H<sub>2</sub>

(c)  $H_2O_2$ 

(d)  $O_3$ 

[Hint: 2Na  $\frac{O_2}{\text{(air)}}$  Na<sub>2</sub>O<sub>2</sub>; 2Na<sub>2</sub>O<sub>2</sub> + 2CO<sub>2</sub>  $\rightarrow$  2Na<sub>2</sub>CO<sub>3</sub> + O<sub>2</sub>]

- 11. Which disproportionates on heating with NaOH?
  - (a)  $P_4$

(c) Cl<sub>2</sub>

(d) All of these

[Hint: 
$$P_4$$
 + 3NaOH + 3H<sub>2</sub>O  $\longrightarrow$  3NaH<sub>2</sub>PO<sub>2</sub> + PH<sub>3</sub>

$$4S + 6NaOH \longrightarrow Na_2S + Na_2S_2O_3 + 3H_2O$$

$$(-2) \qquad (+2)$$

$$3Cl_2 + 6NaOH \longrightarrow 5NaCl + NaClO_3 + 3H_2O$$

- 12. On heating a mixture containing 1 mole each of Li<sub>2</sub>CO<sub>3</sub> and K<sub>2</sub>CO<sub>3</sub>.....is/are formed.
  - (a) 2 moles of CO<sub>2</sub>
- (b) 1 mole of CO<sub>2</sub>
- (c) 1.5 moles of CO<sub>2</sub>
- (d) no carbon dioxide

[Hint: Li<sub>2</sub>CO<sub>3</sub> decomposes while K<sub>2</sub>CO<sub>3</sub> is stable and does not decompose.

$$\begin{array}{ccc} \text{Li}_2\text{CO}_3 & \longrightarrow \text{Li}_2\text{O} & + \text{CO}_2 \text{ ]} \\ \text{I mole} & \text{I mole} \end{array}$$

13. When a substance A reacts with water it produces a combustible gas B and a solution of a substance C in water. When another substance D reacts with this solution of C, it also produces the same gas B on warming, but D can produce B on reaction with dilute sulphuric acid at room temperature. A imparts a deep golden yellow colour to a smokeless flame of Bunsen burner. A, B, C and D respectively are:

- (a) Na, H2, NaOH and Zn
- (b) K, H<sub>2</sub>, KOH and Al
- (c) Ca, H<sub>2</sub>, Ca (OH)<sub>2</sub> and Sn
- (d) CaC2, C2H2, Ca (OH)2 and Sn

[Hint: Na + H<sub>2</sub>O 
$$\longrightarrow$$
 NaOH + H<sub>2</sub>;  
(A) (C) (B)  
 $+Zn$   
(D)
$$Zn + H2SO4  $\longrightarrow$  ZnSO<sub>4</sub> + H<sub>2</sub>]$$

14. What is the heat of solution of sodium chloride from following data?

Hydration energy of Na<sup>+</sup> = -389.4 kJ mol<sup>-1</sup> Hydration energy of Cl<sup>-</sup> = -382.3 kJ mol<sup>-1</sup> Lattice energy of NaCl = -776 kJ mol<sup>-1</sup>

(a)  $+ 8.6 \text{ kJ mol}^{-1}$ 

(b) +  $4.3 \text{ kJ mol}^{-1}$ 

(c)  $-4.3 \text{ kJ mol}^{-1}$ 

(d)  $- 8.6 \, \text{kJ mol}^{-1}$ 

[Hint:  $\Delta H_{\text{sol.}}$  = Hydration energy - Lattice energy Hydration energy of NaCl = -389.4-382.3 = -771.7 kJ mol<sup>-1</sup>]

- **15.** There is loss in mass when mixture of Li<sub>2</sub>CO<sub>3</sub> and Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O is heated strongly. The loss is due to:
  - (a) Li<sub>2</sub>CO<sub>3</sub> only
  - (b) Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O only
  - (c) both Li<sub>2</sub>CO<sub>3</sub> and Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O
  - (d) none of the above
- 16. A colourless solid (X) on heating evolved CO<sub>2</sub> and also gave a white residue, soluble in water. Residue also gave CO<sub>2</sub> when treated with dilute acid (X) is:
  - (a) Na<sub>2</sub>CO<sub>3</sub>

(b) CaCO<sub>3</sub>

(c) NaHCO<sub>3</sub>

(d) Ca(HCO<sub>3</sub>)<sub>2</sub>

White ppt.

[Hint: 
$$2NaHCO_3 \longrightarrow Na_2CO_3 + H_2O + CO_2$$
]

- 18. Select the correct statement:
  - (a) Solubility of alkali hydroxides is in order: CsOH > RbOH > KOH > NaOH > LiOH
  - (b) Solubility of alkali carbonates is in order : Li<sub>2</sub>CO<sub>3</sub> > Na<sub>2</sub>CO<sub>3</sub> > K<sub>2</sub>CO<sub>3</sub> > Rb<sub>2</sub>CO<sub>3</sub> > Cs<sub>2</sub>CO<sub>3</sub>
  - (c) both are correct
  - (d) none of the above is correct
- 19.  $NH_4Cl + (A) \longrightarrow Microcosmic salt$

$$(B) \xrightarrow{\text{Heat} \atop +\text{MnO}} (C)$$
Violet bead

- (A), (B) and (C) are:
- (a) Na<sub>3</sub>PO<sub>4</sub>, NaPO<sub>3</sub>, (Mn)<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>
- (b) Na<sub>2</sub>HPO<sub>4</sub>, Na<sub>3</sub>PO<sub>4</sub>, Mn<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>
- (c) Na<sub>2</sub>HPO<sub>4</sub>, NaPO<sub>3</sub>, Mn(PO<sub>3</sub>)<sub>2</sub>
- (d) Na<sub>2</sub>HPO<sub>4</sub>, NaPO<sub>3</sub>, NaMnPO<sub>4</sub>

[Hint: NH<sub>4</sub>Cl + Na<sub>2</sub>HPO<sub>4</sub>  $\longrightarrow$  NaNH<sub>4</sub>HPO<sub>4</sub>
(A) Microcosmic salt

$$IaPO_3 \xrightarrow{Heat} MnNaPO_4$$
Violet bead

- **20.** The aqueous solution of an unknown sodium salt gives the following reactions:
  - (I) It gives white turbidity with dilute HCl solution.
  - (II) It decolourises a solution of iodine in potassium iodide.
  - (III) It gives a white precipitate with AgNO<sub>3</sub> solution which changes colours and finally becomes black on standing.

The unknown sodium salt is:

- (a) sodium sulphite
- (b) sodium sulphide
- (c) sodium bisulphite
- (d) sodium thiosulphate

 $[\textbf{Hint:} (i) \quad Na_2S_2O_3 + 2HCl \longrightarrow 2NaCl + SO_2 + H_2O + S$

# Assertion-Reason Type Questions

The following questions consist of an Assertion (A) and Reason (R). Use the following key to choose the appropriate

- answer. (a) If both (A) and (R) are correct and (R) is the correct
  - explanation of (A). (b) If both (A) and (R) are correct but (R) is not the correct explanation of (A).
  - If (A) is correct but (R) is not correct.
  - (d) If both (A) and (R) are not correct.
- 1. (A) Lithium resembles magnesium, diagonally placed in IIA
  - (R) The sizes of lithium and magnesium atoms and their ions (Li<sup>+</sup> and Mg<sup>2+</sup>) are nearly the same. [A.I.I.M.S. 1997]

- 2. (A) Lithium chloride is predominantly covalent compound.
  - (R) Electronegativity difference between Li and Cl is small.
    - [LLT. 1998]
- 3. (A) Alkali metals do not occur in native state.
  - (R) Alkali metals are highly reactive metals.
- **4.** (A) K<sub>2</sub>CO<sub>3</sub> cannot be prepared by Solvay process.
  - (R) K<sub>2</sub>CO<sub>3</sub> does not decompose on heating.
- 5. (A) Sodium metal when dissolved in liquid ammonia forms a blue coloured solution.
  - (R) The blue solution is a good conductor of electricity.
- 6. (A) Among the alkali metals, caesium salts exhibit the maximum electrical conductance in aqueous solutions.
  - (R) Bigger the radius of the hydrated cation, higher is the electrical conductance of the aqueous solution.

# POSITION OF ALKALINE EARTH METALS IN PERIODIC TABLE

The group IIA of the periodic table consists of six elements—beryllium, magnesium, calcium, strontium, barium and radium. These elements are collectively called as **alkaline earth metals** because their earths (the old name for oxide) are basic (alkaline) and group IIA is known as **alkaline earth group**. The oxides of three principal members calcium, strontium and barium were known much earlier than the metals themselves. These oxides were alkaline in nature and existed in the earth and were named **alkaline earths**. The metals when discovered were also called alkaline earths. This term is now applied to all the six elements of group IIA. The first member beryllium is less active than other members and shows some abnormal properties like lithium in IA group. However, it shows resemblance with aluminium (a member of IIIrd group), *i.e.*, diagonal relationship. The last member, radium\* is radioactive in nature. Each member of this group occupies a place just after the members of IA group in various periods of periodic table except first period.

IA	Li 3	Na 11	K 19	Rb 37	Cs 55	Fr 87
ΠA	Be 4	Mg 12	Ca 20	Sr 38	Ba 56	Ra 88

The members of this group show a marked resemblance in their properties and possess same electronic configuration. There is gradual gradation in the properties with the increase of atomic number. This justifies their inclusion in the same group of periodic table. The main properties are discussed below for this justification.

## 1. Electronic Configuration

The valence electron configuration of the atoms of the group IIA elements is  $ns^2$ , where n is the period number. The arrangement or the distribution of

<sup>\*</sup>Radium and its all isotopes are radioactive. The longest lived isotope being Ra<sup>226</sup> with half-life 1600 years. This isotope is formed in natural decay series of U<sup>238</sup>.

electrons on	various	subshells	in	the	atoms	of	alkaline	earth	metals:	s give	n below:	
--------------	---------	-----------	----	-----	-------	----	----------	-------	---------	--------	----------	--

Element	At. No.		Electronic Configuration	Configuration of the valency shell
Be	4	2, 2	$1s^2$ , $2s^2$	[He] 2s <sup>2</sup>
Mg	12	2, 8, 2	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$	[Ne] 3s <sup>2</sup>
Ca	20	2, 8, 8, 2	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ , $4s^2$	[Ar] $4s^2$
Sr	38	2, 8, 18, 8, 2	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ , $5s^2$	[Kr] $5s^2$
Ba	56	2, 8, 18, 18, 8, 2	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ , $5s^2$ $5p^6$ , $6s^2$	[Xe] $6s^2$
Ra	88	2, 8, 18, 32, 18, 8, 2	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ $4f^{14}$ , $5s^2$ $5p^6$ $5d^{10}$ , $6s^2$ $6p^6$ , $7s^2$	[Rn] 7s <sup>2</sup>

The outermost shell of these elements has two electrons and the penultimate shell contains 8 electrons except the first member which contains 2 electrons. Since, the last electron enters ns orbital, these are s-block elements. Beryllium shows somewhat abnormal properties as its electronic configuration is slightly different than the rest of the members. Because of their similarity in electronic configuration [noble gas]  $ns^2$ , they are included in the same group, *i.e.*, IIA of the periodic table and closely resemble each other in the physical and chemical properties.

## 3 2. Physical Properties

(a) **Physical state:** All the group IIA elements are metals and too reactive, so that cannot occur in the uncombined state in nature. They are all silvery white metals. They have greyish white lustre when freshly cut, but tarnish soon after their exposure in air due to surface oxidation (Fig. 7.1). They are

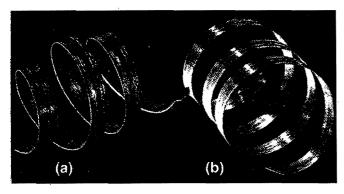

Fig. 7.1 Tarnished (a) and cleaned-up (b) magnesium

soft in nature but harder than alkali metals because metallic bonding is stronger than IA elements due to possession of 2 valency electrons. However, hardness decreases with increase in atomic number.

(b) Atomic and ionic radii: The size of the atom increases gradually from Be to Ra, on account of the presence of an extra energy shell at each step. The atoms are large but smaller than corresponding IA elements since the extra charge on the nucleus attracts the electron cloud inwards. Their ions are also large and size of the ion increases from Be<sup>2+</sup> to Ra<sup>2+</sup>.

•	Be	Mg	Ca	Sr	Ba	Ra
Atomic radii (pm)	112	160	197	215	222	
(Metallic radii) Ionic radii (pm) (M <sup>2</sup>	<sup>t</sup> ) 31	72	100	118	135	148

Atomic volume also increases as the atomic number increases.

(c) **Density:** These metals are denser than alkali metals in the same period because these can be packed more tightly due to their **greater nuclear charge and smaller size.** The density decreases slightly upto calcium and then increases considerably upto radium. Irregular trend is due to the difference in the crystal structure of these elements.

(d) Melting and boiling points: The melting and boiling points of these elements are higher than corresponding alkali metals. This is due to the presence of two electrons in the valency shell and thus, strongly bonded in the solid state. However, melting and boiling points do not show any regular trend because atoms adopt different crystal structures.

	Be	Mg	Ca	Sr	Ba	Ra
m.pt. (K)	1560	924	1124	1062	1002	973
b.pt. (K)	2745	1363	1767	1655	2078	

(e) Ionisation energies and electropositive character: The first and second ionisation energies of these metals decrease from Be to Ba. The second ionisation energy in each case is higher than the first, nearly double the first ionisation energy.

The ionisation energy of last member, radium, is slightly higher than that of barium and it is difficult to explain this anomalous behaviour.

Although, the ionisation energies of these elements are higher than those of alkali metals, yet these are sufficiently low to make these atoms to lose two electrons of their valency shell to form  $M^{2+}$  ions and achieve the inert gas configuration. These

## 7.3 DIFFERENCE BETWEEN ALKALINE EARTH METALS AND ALKALI METALS

Both alkaline earth metals and alkali metals are s-block elements as the last differentiating electron enters the ns-orbital. They resemble with each other in many respects but still there are certain dissimilarities in their properties on account of different number of electrons in the valency shell, smaller atomic radii, high ionisation potential, higher electronegativity, etc. The main points of difference between alkaline earth metals and alkali metals are given below:

	Properties	Alkaline earth metals	Alkali metals
(i)	Electronic configuration	Two electrons are present in the valency shell. The configurations is $ns^2$ .	One electron is present in the valency shell. The configuration is $ns^1$ .
(ii)	Valency	Bivalent.	Monovalent.
(iii)	Electropositive nature	Less electropositive.	More electropositive.
(iv)	Hydroxides	Weak bases, less soluble and decompose on heating.	Strong bases, highly soluble and stable towards heat.
(v)	Bicarbonates	These are not known in free state. Exist only in solution.	These are known in solid state.
(vi)	Carbonates	Insoluble in water. Decompose on heating.	Soluble in water. Do not decompose on heating (Li <sub>2</sub> CO <sub>3</sub> is an exception).
(vii)	Action of nitrogen	Directly combine with nitrogen and form nitrides.	Do not directly combine with nitrogen.
(viii)	Action of carbon	Directly combine with carbon and form carbides.	Do not directly combine with carbon.
(ix)	Nitrates	Decompose on heating evolving a mixture of NO <sub>2</sub> and oxygen.	Decompose on heating evolving only oxygen.
(x)	Solubility of salts	Sulphates, phosphates, fluorides, chromates, oxalates, etc., are insoluble in water.	Sulphates, phosphates, fluorides, chromates, oxalates, etc., are soluble in water.
(xi)	Physical properties	Are less reactive and comparatively harder metals. High melting points. Diamagnetic.	Soft, low melting points. Paramagnetic.
(xii)	Hydration of compounds	The compounds are extensively hydrated. MgCl <sub>2</sub> ·6H <sub>2</sub> O,	The compounds are less hydrated. NaCl, KCl and
(xiii)	Reducing power	CaCl <sub>2</sub> ·6H <sub>2</sub> O and BaCl <sub>2</sub> ·2H <sub>2</sub> O are hydrated chlorides. Weaker, as ionisation potential values are high and oxidation potential values are low.	RbCl form non-hydrated chlorides. Stronger, as ionisation potential values are low and oxidation potential values are high.

# 7.4 ABNORMAL BEHAVIOUR OF BERYLLIUM

Beryllium is a much less abundant alkaline earth metal, although masses of the mineral beryl (Be<sub>3</sub>Al<sub>2</sub>Si<sub>6</sub>O<sub>18</sub>) that weigh as much as a ton have been found. Pure beryl is colourless, but impurities give it colour; chromium as an impurity makes beryl into emerald (Fig. 7.2) and iron makes it aquamarine. Beryllium differs from rest of the alkaline earth metals on account of its small atomic size, high electronegativity and slight difference in electronic configuration. Be<sup>2+</sup> is very small. It exerts a high polarising effect on any anion associated with it. On account of this, beryllium compounds show covalent character. Its compounds have low melting points and are soluble in organic solvents. These are hydrolysed in water.

## The main points of difference are given below:

- (i) It is the hardest of all alkaline earth metals: This is due to the fact that maximum metallic bonding is present on account of the smallest size amongst alkaline earth metals.
- (ii) The melting and boiling points of the beryllium are the highest: This is also due to maximum metallic bonding.
- (iii) It is not affected by atmosphere: Be is least reactive as its ionisation potential is high. However, it does react with oxygen and nitrogen at high temperatures.
- (iv) It does not decompose water: This is due to low value of oxidation potential.

- (v) It has the tendency to form covalent compounds: The polarisation effect of Be<sup>2+</sup> ion is high due to its high charge density. The large distortion of electron cloud of the anion brings covalent character. Be has high value of electronegativity (1.5) and when it reacts with another element, the electronegativity difference is not so large and the bond is, therefore, covalent.
- (vi) It does not react directly with hydrogen: Beryllium hydride can, however, be formed by reducing BeCl<sub>2</sub> with LiAlH<sub>4</sub>. Beryllium hydride is a covalent compound. It is polymeric solid,  $(BeH_2)_n$ . It contains hydrogen bridges between beryllium atoms.

The hydrides of Ca, Sr and Ba are largely ionic due to greater electropositive character.

(vii) It dissolves in alkalies with evolution of hydrogen:

Be + 2NaOH + 2H<sub>2</sub>O 
$$\longrightarrow$$
 Na<sub>2</sub>BeO<sub>2</sub>·2H<sub>2</sub>O + H<sub>2</sub>  
Sodium beryllate

other alkaline earth metals do not react with alkalies.

- (viii) It does not liberate hydrogen from acids readily: This is due to the fact that Be has lowest oxidation potential amongst alkaline earth metals.
- (ix) Its oxide is amphoteric in nature: Be is thus weak electropositive in nature.

$$BeO + H2SO4 \longrightarrow BeSO4 + H2O$$

$$BeO + 2NaOH \longrightarrow Na2BeO2 + H2O$$

The oxide is sparingly soluble in water as it has high degree of covalency. It has high melting point (approx. 2500°C). The high melting point of BeO is due to its polymeric nature.

The oxides of other alkaline earth metals are basic, soluble and ionic in nature. The basic nature increases in moving down the group.

BeO has a 4:4 zinc sulphide (Wurtzite) structure, but all others have a 6:6 sodium chloride structure.

(x) Its hydroxide is amphoteric in nature: Be is thus weak electropositive in nature.

$$Be(OH)_2 + 2HCl \longrightarrow BeCl_2 + 2H_2O$$
  
 $Be(OH)_2 + 2NaOH \longrightarrow Na_2BeO_2 + 2H_2O$ 

The hydroxide is insoluble in water. It is covalent in nature. The hydroxides of other alkaline earth metals are basic, ionic and their solubility increases on moving from Mg(OH)<sub>2</sub> to Ba(OH)<sub>2</sub>.

## (xi) Its carbide (Be<sub>2</sub>C) on hydrolysis evolves methane : $Be_2C + 4H_2O \longrightarrow 2Be(OH)_2 + CH_4$

The carbides of other alkaline earth metals  $(MC_2)$  evolve acetylene on hydrolysis.

(xii) Its carbonate (BeCO<sub>3</sub>) is not stable towards heat:

The instability is due to strong polarising effect of small  $Be^{2+}$  ion on the large  $CO_3^{2-}$  ion.

- (xiii) Its nitride ( $Be_3N_2$ ) is volatile:  $Be_3N_2$  is covalent, while nitrides of other alkaline earth metals are ionic crystalline compounds.
- (xiv) Its sulphate is soluble in water: It is due to high degree of solvation of small  $Be^{2+}$  ions.
- (xv) BeCl<sub>2</sub> is a covalent compound: It does not conduct electricity in fused state. It is soluble in organic solvents and acts as a Lewis acid. It fumes in air.

The chlorides of other alkaline earth metals are ionic and good conductors of electricity in fused state and in solutions.

- (xvi) It is rendered passive by concentrated nitric acid: Nitric acid is an oxidising agent. It forms unreactive thin layer of oxide on its surface and makes the metal passive.
- (xvii) Its compounds do not impart any colour to flame: Very high energy is required to excite electron from lowest energy shell.
- (xviii) Its salts can never have more than four molecules of water of crystallisation as it has only four available orbitals in its valency shell.

Other alkaline earth metals can extend their coordination number to 6 by using d-orbitals.

(xix) It has strong tendency to form complex compounds: Beryllium ion, on account of its small size, forms stable complexes, such as  $[BeF_3]^-$  or  $[BeF_4]^{2-}$ . It forms many chelate like complexes specially with oxygen donors.

- (xx) It has the tendency to form alloys: The metal and its alloys have the following important applications.
  - (a) Low density of beryllium makes it important in the formation of missiles and satellites.
  - (b) Much of the metal that is produced is added in small amounts to copper, the small beryllium atoms pin the copper atoms together in an interstitial alloy that is more rigid than pure copper but still conducts electricity well.
  - (c) The hard electrically conducting alloy is formed for non-sparking tools for use in oil refineries and grain elevators, where there is a risk of explosions.
  - (d) Beryllium is used as windows for X-ray tubes, because beryllium atoms have so few electrons, thin sheets of the metal are transparent to X-rays and allows the rays to escape.

**Note:** The element beryllium occurs mainly as *beryl* 3BeO, Al<sub>2</sub>O<sub>3</sub>.6SiO<sub>2</sub>. Sometime the crystals are so big that they weigh several tonnes. The gemstone *emerald* is a form of *beryl*, its green colour is caused by the Cr<sup>3+</sup> ions present as impurities.

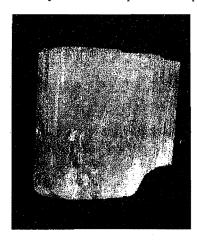

Fig. 7.2 An emerald is a crystal of *beryl* with some Cr<sup>3+</sup> ions which are responsible for the colour

# SIMILARITIES (DIAGONAL RELATIONSHIP) BETWEEN BERYLLIUM AND ALUMINIUM

Beryllium shows some similarities in properties with aluminium, the second typical element of group IIIA (next group in Mendeleev's periodic table) of the next higher period. This type of relationship between diagonally placed elements is called diagonal relationship (one of the characteristics of Mendeleev's periodic table).

$$3MgO + 2Al \longrightarrow 3Mg + Al_2O_3$$
  
 $3MgO + CaC_2 \longrightarrow 3Mg + CaO + 2CO$ 

The reduction is done at 2000°C in vacuum. The vapours of magnesium are condensed.

(ii) Electrolysis of anhydrous magnesium chloride: Carnallite (KCl-MgCl<sub>2</sub>·6H<sub>2</sub>O) is a hydrated compound. It cannot be dehydrated by heating because the water of crystallisation reacts chemically with magnesium chloride to form magnesium oxychloride and finally magnesium oxide.

$$\begin{array}{c} MgCl_2 \cdot 6H_2O \xrightarrow{Heated} MgCl_2 \cdot 2H_2O \xrightarrow{Heated} \\ Hexahydrate & Dihydrate \\ \hline \\ Mg_2OCl_2 \xrightarrow{Strongly} MgO \\ Oxychloride & heated in air \end{array}$$

To make it anhydrous, it is first heated in air and then in a current of HCl gas.

Anhydrous magnesium chloride can also be obtained from MgO or sea water. Chlorine is passed over red hot mixture of MgO and carbon.

$$MgO + C + Cl_2 \longrightarrow MgCl_2 + CO$$

Sea water contains magnesium compounds. It is treated with calcium hydroxide when magnesium hydroxide gets precipitated. It is dissolved in dilute HCl. The solution is then concentrated when hydrated magnesium chloride crystallises out. It is dehydrated as described above.

$$\begin{array}{c} Mg^{2+} + Ca(OH)_2 & \longrightarrow & Mg(OH)_2 + Ca^{2+} \\ (Sea \ water, \ MgCl_2 \ or \ MgSO_4) & ppt. \\ \\ Mg(OH)_2 + 2HCl & \longrightarrow & MgCl_2 \cdot 6H_2O \\ \\ MgCl_2 \cdot 6H_2O & \xrightarrow{Heated} & MgCl_2 + 6H_2O \\ \\ & & Anhydrous \\ \end{array}$$

Finally, the magnesium chloride is dried. The anhydrous magnesium chloride is fused with NaCl and anhydrous calcium

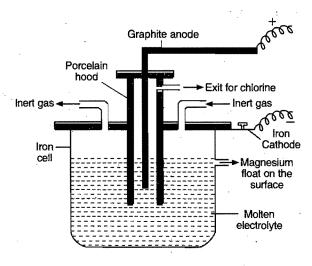

Fig. 7.3 An electrolytic cell

chloride in the ratio of 35% (MgCl<sub>2</sub>); 50% (NaCl) and 15% (CaCl<sub>2</sub>). The mixture is electrolysed at 700°C in presence of an inert gas in an electrolytic cell as shown in Fig. 7.3.

Magnesium is produced at cathode and chlorine at the anode.

$$MgCl_2 \xrightarrow{Electrolysis} Mg + Cl_2$$

Magnesium being lighter than the fused mass floats on the surface from where it is removed periodically by perforated ladles.

The purpose of addition of NaCl and CaCl<sub>2</sub> to anhydrous MgCl<sub>2</sub> is to lower the fusion temperature and make the fused mass good conductor of electricity.

## **Properties**

**Physical Properties:** Magnesium is a silvery-white metal. It is a light metal. It is fairly hard and is malleable and ductile. Its great advantage is its low density (1.74 g/cm<sup>3</sup>), which is only two-thirds that of aluminium 2.70 g/cm<sup>3</sup>. It is sold in the form of ribbons or wire. It melts at 650°C. It is good conductor of heat and electricity.

Chemical Properties: (i) Reaction with air: Pure magnesium metal is a relatively reactive element. It is not affected by dry air. It is slowly tarnished in moist air.

Once magnesium metal has been ignited, it burns vigorously in air to form the oxide with bright white light forming a dense smoke.

$$\begin{array}{ccc} 2Mg \, + \, \mathrm{O}_2 & \longrightarrow & 2Mg\mathrm{O} \\ 3Mg \, + \, N_2(\mathrm{Air}) & \longrightarrow & Mg_3N_2 \end{array}$$

(ii) Reaction with water: Magnesium is not affected by cold water. It decomposes steam or boiling water with evolution of hydrogen.

$$Mg + 2H_2O \longrightarrow Mg(OH)_2 + H_2$$

(iii) Reaction with acids: It displaces hydrogen from dilute acids.

$$Mg + 2HCl \longrightarrow MgCl_2 + H_2$$
  
 $Mg + H_2SO_4 \longrightarrow MgSO_4 + H_2$   
 $Mg + 2HNO_3 \longrightarrow Mg(NO_3)_2 + H_2$ 

With hot concentrated H<sub>2</sub>SO<sub>4</sub>, it evolves SO<sub>2</sub>.

$$\begin{array}{ccc} H_2SO_4 & \longrightarrow & H_2O + SO_2 + O \\ Mg + O & \longrightarrow & MgO \\ MgO + H_2SO_4 & \longrightarrow & MgSO_4 + H_2O \\ \hline Mg + 2H_2SO_4 & \longrightarrow & MgSO_4 + SO_2 + 2H_2O \\ \end{array}$$

(iv) Reaction with halogens: Magnesium on heating with halogens, readily form halides.

$$Mg + X_2 \longrightarrow MgX_2$$
 $(X \text{ may be F, Cl, Br or I})$ 

(v) Reducing property: Magnesium acts as a strong reducing agent as it has great affinity for oxygen at high temperature. It even burns in the atmosphere of CO<sub>2</sub>, CO, SO<sub>2</sub>, NO, etc.

## The following are the causes of diagonal relationship:

- (a) The polarising power of Be<sup>2+</sup> and Al<sup>3+</sup> ions is high. Consequently the compounds develop covalent nature.
- (b) The standard oxidation potential values of both the elements are very close to each other.
- (c) The electronegativity values of both the elements are the same.

## The similarities in properties are listed below:

- (i) In nature, both the elements occur together in the mineral, beryl, 3BeO·Al<sub>2</sub>O<sub>3</sub>·6SiO<sub>2</sub>.
  - (ii) Both are not affected by atmosphere.
  - (iii) They do not decompose water.
- (iv) Both become passive when treated with concentrated HNO<sub>3</sub>.
  - (v) Both dissolve in caustic alkalies liberating hydrogen.

$$Be + 2NaOH \longrightarrow Na_2BeO_2 + H_2$$

$$2AI + 2NaOH + 2H_2O \longrightarrow 2NaAIO_2 + 3H_2$$
Sod. meta

(vi) Both BeO and Al<sub>2</sub>O<sub>3</sub> are amphoteric in nature.

$$BeO + H_2SO_4 \longrightarrow BeSO_4 + H_2O$$

$$BeO + 2NaOH \longrightarrow Na_2BeO_2 + H_2O$$

$$Al_2O_3 + 6HCl \longrightarrow 2AlCl_3 + 3H_2O$$

$$Al_2O_3 + 2NaOH \longrightarrow 2NaAlO_2 + H_2O$$

Oxides are extremely hard, non-volatile and have high melting points.

(vii) The hydroxides are also amphoteric in nature.

$$Be(OH)_2 + 2HCl \longrightarrow BeCl_2 + 2H_2O$$

$$Be(OH)_2 + 2NaOH \longrightarrow Na_2BeO_2 + 2H_2O$$

$$Al(OH)_3 + 3HCl \longrightarrow AlCl_3 + 3H_2O$$

$$Al(OH)_3 + NaOH \longrightarrow NaAlO_2 + 2H_2O$$

The hydroxides are insoluble in water and decompose on heating into corresponding oxides.

$$Be(OH)_2 \longrightarrow BeO + H_2O$$

$$2Al(OH)_3 \longrightarrow Al_2O_3 + 3H_2O$$

(viii) Beryllium carbide ( $Be_2C$ ) and aluminium carbide ( $Al_4C_3$ ) both evolve methane on treatment with water.

$$Be_2C + 2H_2O \longrightarrow 2BeO + CH_4$$
  
 $Al_4C_3 + 6H_2O \longrightarrow 2Al_2O_3 + 3CH_4$ 

(ix) Both the metals react with halogens and form halides. Chlorides can also be formed in a similar way.

$$BeO + C + Cl_2 \longrightarrow BeCl_2 + CO$$

$$Al_2O_3 + 3C + 3Cl_2 \longrightarrow 2AlCl_3 + 3CO$$

The halides (except fluorides) are covalent in nature. They have low melting points and are hydrolysed by water. They dissolve in organic solvents and fume in moist air. The halides behave as Lewis acids.

(x) Beryllium and aluminium both form polymeric covalent hydrides.

(xi) Both combine with nitrogen when strongly heated in its atmosphere.

$$3Be + N_2 \longrightarrow Be_3N_2$$

$$2Al + N_2 \longrightarrow 2AlN$$

Nitrides on action with water evolve ammonia.

$$Be_3N_2 + 6H_2O \longrightarrow 3Be(OH)_2 + 2NH_3$$
  
 $AlN + 3H_2O \longrightarrow Al(OH)_3 + NH_3$ 

- (xii) Both the metals are obtained by the electrolysis of their fused salts in the presence of fluorides.
- (xiii)  $Be^{2+}$  and  $Al^{3+}$  ions have strong tendency to form chelate type complexes. Both form fluoride complexes, like  $[BeF_4]^{2-}$ ,  $[AlF_6]^{3-}$  respectively.
  - (xiv) The carbonates of both the metals are unstable.
- (xv) Both the ions give hydrated ions in solution (aqueous) like  $[Be(H_2O)_4]^{2+}$  and  $[Al(H_2O)_6]^{3+}$  respectively.
- (xvi) The salts of both Be and Al do not impart a colour to the flame when heated in it.

## 7 MAGNESIUM

**Occurrence:** Magnesium does not occur free in nature. The british chemist Humphry Davy discovered the pure element magnesium in 1808. The name magnesium comes from the name of the mineral **magnesite.** In addition to minerals such as magnesite (MgCO<sub>3</sub>), dolomite (MgCO<sub>3</sub>·CaCO<sub>3</sub>), kieserite (MgSO<sub>4</sub>·H<sub>2</sub>O), epsom salt (MgSO<sub>4</sub>·7H<sub>2</sub>O), carnallite (KCl·MgCl<sub>2</sub>·6H<sub>2</sub>O), asbestos [CaMg<sub>3</sub>(SiO<sub>3</sub>)<sub>4</sub>], it is found in sea water. However magnesium ion, Mg<sup>2+</sup>, is the third most abundant dissolved ion in the oceans, after Cl<sup>-</sup> and Na<sup>+</sup>. The oceans, therefore, are a great source for the supply of the magnesium ion, from which the metal can be obtained easily. It is an essential constituent of chlorophyll, the green colouring matter of plants.

**Extraction:** It is usually extracted by the electrolysis of fused oxide or fused anhydrous magnesium chloride.

(i) From magnesite: The magnesite ore (MgCO<sub>3</sub>) is calcined into magnesium oxide (magnesia).

$$MgCO_3 \xrightarrow{Heated} MgO + CO_2$$

Magnesium may be obtained either by electrolysis or by thermal reduction of magnesium oxide. The oxide is dissolved in a mixture of molten fluorides of magnesium, barium and sodium. The electrolysis of molten mixture is done by using carbon rods as anodes which suspend in molten mass and cast iron rods as cathodes at 650°C. On electrolysis magnesium is obtained in molten state.

The thermal reduction of magnesium oxide can be done by using reducing agents like carbon, silicon, aluminium or calcium carbide.

$$MgO + C \longrightarrow Mg + CO$$
  
 $2MgO + Si \longrightarrow 2Mg + SiO_2$ 

## The following are the causes of diagonal relationship:

- (a) The polarising power of Be<sup>2+</sup> and A1<sup>3+</sup> ions is high. Consequently the compounds develop covalent nature.
- (b) The standard oxidation potential values of both the elements are very close to each other.
- (c) The electronegativity values of both the elements are the same.

## The similarities in properties are listed below:

- (i) In nature, both the elements occur together in the mineral, beryl, 3BeO·Al<sub>2</sub>O<sub>3</sub>·6SiO<sub>2</sub>.
  - (ii) Both are not affected by atmosphere.
  - (iii) They do not decompose water.
- (iv) Both become passive when treated with concentrated HNO<sub>3</sub>.
  - (v) Both dissolve in caustic alkalies liberating hydrogen.

$$Be + 2NaOH \longrightarrow Na_2BeO_2 + H_2$$

$$2Al + 2NaOH + 2H_2O \longrightarrow 2NaAlO_2 + 3H_2$$
Sod. meta

(vi) Both BeO and Al<sub>2</sub>O<sub>3</sub> are amphoteric in nature.

$$\begin{array}{ccc} BeO + H_2SO_4 & \longrightarrow & BeSO_4 + H_2O \\ BeO + 2NaOH & \longrightarrow & Na_2BeO_2 + H_2O \\ Al_2O_3 + 6HCl & \longrightarrow & 2AlCl_3 + 3H_2O \\ Al_2O_3 + 2NaOH & \longrightarrow & 2NaAlO_2 + H_2O \end{array}$$

Oxides are extremely hard, non-volatile and have high melting points.

(vii) The hydroxides are also amphoteric in nature.

$$Be(OH)_2 + 2HCl \longrightarrow BeCl_2 + 2H_2O$$

$$Be(OH)_2 + 2NaOH \longrightarrow Na_2BeO_2 + 2H_2O$$

$$Al(OH)_3 + 3HCl \longrightarrow AlCl_3 + 3H_2O$$

$$Al(OH)_3 + NaOH \longrightarrow NaAlO_2 + 2H_2O$$

The hydroxides are insoluble in water and decompose on heating into corresponding oxides.

$$\begin{array}{ccc} Be(OH)_2 & \longrightarrow & BeO + H_2O \\ 2Al(OH)_3 & \longrightarrow & Al_2O_3 + 3H_2O \end{array}$$

(viii) Beryllium carbide ( $Be_2C$ ) and aluminium carbide ( $Al_4C_3$ ) both evolve methane on treatment with water.

$$Be_2C + 2H_2O \longrightarrow 2BeO + CH_4$$
  
 $Al_4C_3 + 6H_2O \longrightarrow 2Al_2O_3 + 3CH_4$ 

(ix) Both the metals react with halogens and form halides. Chlorides can also be formed in a similar way.

$$BeO + C + Cl_2 \longrightarrow BeCl_2 + CO$$
  
 $Al_2O_3 + 3C + 3Cl_2 \longrightarrow 2AlCl_3 + 3CO$ 

The halides (except fluorides) are covalent in nature. They have low melting points and are hydrolysed by water. They dissolve in organic solvents and fume in moist air. The halides behave as Lewis acids.

(x) Beryllium and aluminium both form polymeric covalent hydrides.

(xi) Both combine with nitrogen when strongly heated in its atmosphere.

$$3Be + N_2 \longrightarrow Be_3N_2$$

$$2Al + N_2 \longrightarrow 2AlN$$

Nitrides on action with water evolve ammonia.

$$Be_3N_2 + 6H_2O \longrightarrow 3Be(OH)_2 + 2NH_3$$
  
 $AlN + 3H_2O \longrightarrow Al(OH)_3 + NH_3$ 

- (xii) Both the metals are obtained by the electrolysis of their fused salts in the presence of fluorides.
- (xiii) Be<sup>2+</sup> and Al<sup>3+</sup> ions have strong tendency to form chelate type complexes. Both form fluoride complexes, like [BeF<sub>4</sub>]<sup>2-</sup>, [AlF<sub>6</sub>]<sup>3-</sup> respectively.
  - (xiv) The carbonates of both the metals are unstable.
- (xv) Both the ions give hydrated ions in solution (aqueous) like  $[Be(H_2O)_4]^{2+}$  and  $[Al(H_2O)_6]^{3+}$  respectively.
- (xvi) The salts of both Be and AI do not impart a colour to the flame when heated in it.

## **MAGNESIUM**

**Occurrence:** Magnesium does not occur free in nature. The british chemist Humphry Davy discovered the pure element magnesium in 1808. The name magnesium comes from the name of the mineral **magnesite.** In addition to minerals such as magnesite (MgCO<sub>3</sub>), dolomite (MgCO<sub>3</sub>·CaCO<sub>3</sub>), kieserite (MgSO<sub>4</sub>·H<sub>2</sub>O), epsom salt (MgSO<sub>4</sub>·7H<sub>2</sub>O), camallite (KCl·MgCl<sub>2</sub>·6H<sub>2</sub>O), asbestos [CaMg<sub>3</sub>(SiO<sub>3</sub>)<sub>4</sub>], it is found in sea water. However magnesium ion, Mg<sup>2+</sup>, is the third most abundant dissolved ion in the oceans, after Cl<sup>-</sup> and Na<sup>+</sup>. The oceans, therefore, are a great source for the supply of the magnesium ion, from which the metal can be obtained easily. It is an essential constituent of chlorophyll, the green colouring matter of plants.

**Extraction:** It is usually extracted by the electrolysis of fused oxide or fused anhydrous magnesium chloride.

(i) From magnesite: The magnesite ore (MgCO<sub>3</sub>) is calcined into magnesium oxide (magnesia).

$$MgCO_3 \xrightarrow{Heated} MgO + CO_2$$

Magnesium may be obtained either by electrolysis or by thermal reduction of magnesium oxide. The oxide is dissolved in a mixture of molten fluorides of magnesium, barium and sodium. The electrolysis of molten mixture is done by using carbon rods as anodes which suspend in molten mass and cast iron rods as cathodes at 650°C. On electrolysis magnesium is obtained in molten state.

The thermal reduction of magnesium oxide can be done by using reducing agents like carbon, silicon, aluminium or calcium carbide.

$$MgO + C \longrightarrow Mg + CO$$
  
 $2MgO + Si \longrightarrow 2Mg + SiO_2$ 

$$3MgO + 2Al \longrightarrow 3Mg + Al_2O_3$$
  
 $3MgO + CaC_2 \longrightarrow 3Mg + CaO + 2CO$ 

The reduction is done at 2000°C in vacuum. The vapours of magnesium are condensed.

(ii) Electrolysis of anhydrous magnesium chloride: Carnallite (KCl·MgCl $_2$ ·6H $_2$ O) is a hydrated compound. It cannot be dehydrated by heating because the water of crystallisation reacts chemically with magnesium chloride to form magnesium oxychloride and finally magnesium oxide.

$$\begin{array}{c} MgCl_2 \cdot 6H_2O \xrightarrow{Heated} MgCl_2 \cdot 2H_2O \xrightarrow{Heated} \\ Hexahydrate & Dihydrate \\ \hline \\ Mg_2OCl_2 \xrightarrow{Strongly} MgO \\ Oxychloride & heated in air \end{array}$$

To make it anhydrous, it is first heated in air and then in a current of HCl gas.

Anhydrous magnesium chloride can also be obtained from MgO or sea water. Chlorine is passed over red hot mixture of MgO and carbon.

$$MgO + C + Cl_2 \longrightarrow MgCl_2 + CO$$

Sea water contains magnesium compounds. It is treated with calcium hydroxide when magnesium hydroxide gets precipitated. It is dissolved in dilute HCl. The solution is then concentrated when hydrated magnesium chloride crystallises out. It is dehydrated as described above.

$$\begin{array}{c} \text{Mg}^{2+} + \text{Ca}(\text{OH})_2 & \longrightarrow & \text{Mg}(\text{OH})_2 + \text{Ca}^{2+} \\ \text{(Sea water, MgCl}_2 \text{ or MgSO}_4) & \text{ppt.} \\ \\ \text{Mg}(\text{OH})_2 + 2\text{HCl} & \longrightarrow & \text{MgCl}_2 \cdot 6\text{H}_2\text{O} \\ \\ \text{MgCl}_2 \cdot 6\text{H}_2\text{O} & \xrightarrow{\text{Heated}} & \text{MgCl}_2 + 6\text{H}_2\text{O} \\ \hline \\ \text{HCl}(g) & \text{Anhydrous} \end{array}$$

Finally, the magnesium chloride is dried. The anhydrous magnesium chloride is fused with NaCl and anhydrous calcium

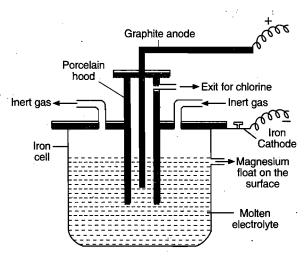

Fig. 7.3 An electrolytic cell

chloride in the ratio of 35% (MgCl<sub>2</sub>); 50% (NaCl) and 15% (CaCl<sub>2</sub>). The mixture is electrolysed at 700°C in presence of an inert gas in an electrolytic cell as shown in Fig. 7.3.

Magnesium is produced at cathode and chlorine at the anode.

$$MgCl_2 \xrightarrow{Electrolysis} Mg + Cl_2$$

Magnesium being lighter than the fused mass floats on the surface from where it is removed periodically by perforated ladles.

The purpose of addition of NaCl and CaCl<sub>2</sub> to anhydrous MgCl<sub>2</sub> is to lower the fusion temperature and make the fused mass good conductor of electricity.

## **Properties**

**Physical Properties:** Magnesium is a silvery-white metal. It is a light metal. It is fairly hard and is malleable and ductile. Its great advantage is its low density (1.74 g/cm<sup>3</sup>), which is only two-thirds that of aluminium 2.70 g/cm<sup>3</sup>. It is sold in the form of ribbons or wire. It melts at 650°C. It is good conductor of heat and electricity.

Chemical Properties: (i) Reaction with air: Pure magnesium metal is a relatively reactive element. It is not affected by dry air. It is slowly tarnished in moist air.

Once magnesium metal has been ignited, it burns vigorously in air to form the oxide with bright white light forming a dense smoke.

$$2Mg + O_2 \longrightarrow 2MgO$$

$$3Mg + N_2(Air) \longrightarrow Mg_3N_2$$

(ii) Reaction with water: Magnesium is not affected by cold water. It decomposes steam or boiling water with evolution of hydrogen.

$$Mg + 2H_2O \longrightarrow Mg(OH)_2 + H_2$$

(iii) Reaction with acids: It displaces hydrogen from dilute acids.

 $Mg + 2HCl \longrightarrow MgCl_2 + H_2$ 

$$\begin{array}{cccc} Mg + H_2SO_4 & \longrightarrow & MgSO_4 + H_2 \\ Mg + 2HNO_3 & \longrightarrow & Mg(NO_3)_2 + H_2 \\ \end{array}$$
 With hot concentrated  $H_2SO_4$ , it evolves  $SO_2$ .
$$\begin{array}{cccc} H_2SO_4 & \longrightarrow & H_2O + SO_2 + O \\ Mg + O & \longrightarrow & MgO \end{array}$$

$$\frac{\text{MgO} + \text{H}_2\text{SO}_4 \longrightarrow \text{MgSO}_4 + \text{H}_2\text{O}}{\text{Mg} + 2\text{H}_2\text{SO}_4 \longrightarrow \text{MgSO}_4 + \text{SO}_2 + 2\text{H}_2\text{O}}$$

(iv) Reaction with halogens: Magnesium on heating with halogens, readily form halides.

$$Mg + X_2 \longrightarrow MgX_2$$
(X may be F, Cl, Br or I)

(v) Reducing property: Magnesium acts as a strong reducing agent as it has great affinity for oxygen at high temperature. It even burns in the atmosphere of CO<sub>2</sub>, CO, SO<sub>2</sub>, NO, etc.

$$2Mg + CO_2 \longrightarrow 2MgO + C$$
  
 $2Mg + SO_2 \longrightarrow 2MgO + S$   
 $5Mg + 2NO \longrightarrow 2MgO + Mg_3N_2$ 

It reduces oxides of metals and non-metals

$$B_2O_3 + 3Mg \longrightarrow 3MgO + 2B$$

With KClO<sub>3</sub>, it burns with explosion

$$3Mg + KClO_3 \longrightarrow 3MgO + KCl$$

(vi) Formation of Grignard reagent: Magnesium dissolves in ether solution of alkyl halides and forms organometallic compounds known as Grignard reagents. These reagents are used in organic synthesis.

$$Mg + RI \longrightarrow Mg \stackrel{R}{\swarrow}$$

Alkyl magnesium iodide

(vii) Displacement reactions: Since, magnesium is highly electropositive metal, it displaces less electropositive metals from their salts solutions.

$$Mg + 2AgNO_3 \longrightarrow Mg(NO_3)_2 + 2Ag$$

(viii) Reaction with FeCl<sub>3</sub> or  $NH_4Cl$  solution: Magnesium dissolves in FeCl<sub>3</sub> or  $NH_4Cl$  solution with evolution of hydrogen.

$$[FeCl_3 + 3H_2O \longrightarrow Fe(OH)_3 + 3HCl] \times 2$$

$$[Mg + 2HCl \longrightarrow MgCl_2 + H_2] \times 3$$

$$3Mg + 2FeCl_3 + 6H_2O \longrightarrow 3MgCl_2 + 2Fe(OH)_3 + 3H_2$$

$$Mg + 2NH_4Cl \longrightarrow MgCl_2 + 2NH_3 + H_2$$

## Uses

- (i) It is used for the extraction of boron and silicon.
- (ii) Magnesium ribbon alongwith barium peroxide is used as ignition mixture in aluminothermite process.
- (iii) Magnesium powder mixed with potassium chlorate is used in flash bulbs for photography.
  - (iv) It is used for making Grignard reagents.
- (v) It is employed as a deoxidiser in metallurgy and for the removal of last traces of air from radio-valves.
- (vi) Large quantities of magnesium oxide are used in animal feed supplements because magnesium ion is an important nutrient for animals. The ion is also important for human nutrition.
- (vii) Magnesium metal is also used as a reducing agent in the manufacture of titanium and zirconium from their tetrachlorides.

$$ZrCl_4 + 2Mg \longrightarrow Zr + 2MgCl_2$$

(viii) Most commercial aluminium metal contains some percentage of magnesium, which improves the hardness and corrosion resistance of the aluminium.

(ix) Its alloys, however, contain aluminium and small quantities of other metals to impart both strength and corrosion resistance. Magnesium alloys are used to make automobile, aircraft parts, as well as power-tools. The important alloys are:

Magnalium 95% Al Used in the construction of airships, 5% Mg balances and pistons of motor engines. Electron metal 95% Mg 4.5% Zn Used in the construction of air-crafts. 0.5% Cu 95% Al Duralumin Its strength and toughness is comp-0.5% Mg arable with mild steel. It is used for 0.5% Mn making airships. 4% Cu

## COMPOUNDS OF MAGNESIUM

## 1. Magnesium Oxide, MgO, (Magnesia)

**Preparation:** It can be prepared by following reactions.

$$2Mg + O_{2} \xrightarrow{Burning} 2MgO$$

$$Mg(OH)_{2} \xrightarrow{Heated} MgO + H_{2}O$$

$$2Mg(NO_{3})_{2} \xrightarrow{Heated} 2MgO + 4NO_{2} + O_{2}$$

$$MgCO_{3} \xrightarrow{Heated} MgO + CO_{2}$$

**Properties:** It is a light infusible white powder. It fuses at 2800°C. It is quite stable at high temperature and is a good thermal insulator. It is slightly soluble in water and forms magnesium hydroxide.

$$MgO + H_2O \longrightarrow Mg(OH)_2$$

It is basic in nature. It reacts with acids to form corresponding salts.

$$\begin{array}{ccc} MgO + 2HCl & \longrightarrow & MgCl_2 + H_2O \\ MgO + H_2SO_4 & \longrightarrow & MgSO_4 + H_2O \end{array}$$

It is reduced by carbon at very high temperature.

$$MgO + C \longrightarrow Mg + CO$$

Magnesium oxide when mixed with a saturated solution of magnesium chloride sets to a hard mass like cement known as **magnesia cement** or **Sorel cement**. The composition is MgCl<sub>2</sub>·5MgO·xH<sub>2</sub>O.

Uses: It is used:

- (i) in medicine as antacid.
- (ii) refractory bricks for furnaces.
- (iii) as an insulator when mixed with asbestos for lagging steam pipes and boilers.
- (iv) as an adsorbent in the manufacture of dynamite and in the vulcanization of rubber.
- (v) for making Sorel cement which is employed in dental filling, in cementing glass and porcelain, in plaster casting, etc.

## ■ 2. Magnesium Hydroxide, Mg(OH)<sub>2</sub>

**Preparation:** It is prepared by dissolving magnesium oxide in water or by treating magnesium salt with an alkali.

$$\begin{array}{ccc} MgO + H_2O & \longrightarrow & Mg(OH)_2 \\ MgCl_2 + Ca(OH)_2 & \longrightarrow & Mg(OH)_2 + CaCl_2 \\ MgCl_2 + 2NaOH & \longrightarrow & Mg(OH)_2 + 2NaCl_2 \end{array}$$

**Properties:** It is a white powder. It is sparingly soluble in water. It is basic in nature and forms salts with acids. It decomposes on heating. It readily dissolves in strong solution of  $NH_4Cl$ .

$$Mg(OH)_2 + 2NH_4Cl \iff MgCl_2 + 2NH_4OH$$

Uses: A suspension of Mg(OH)<sub>2</sub> in water is used in medicine as an antacid under the name, *milk of magnesia*, because the magnesium hydroxide reacts to neutralize excess of hydrochloric acid present in the stomach.

## 3. Magnesium Carbonate, MgCO<sub>3</sub>

It is found in nature as magnesite (MgCO<sub>3</sub>) and dolomite (MgCO<sub>3</sub>·CaCO<sub>3</sub>).

**Preparation:** It can be prepared by adding sodium bicarbonate to a hot solution of magnesium salt.

$$MgSO_4 + 2NaHCO_3 \longrightarrow MgCO_3 + Na_2SO_4 + H_2O + CO_2$$

The magnesium carbonate cannot be obtained by the addition of sodium carbonate to the solution of magnesium salt. A white precipitate of a basic carbonate of composition  $3MgCO_3 Mg(OH)_2 3H_2O$  is obtained. It is known as **magnesia alva.** It is suspended in water and  $CO_2$  is passed when magnesium bicarbonate known as **fluid magnesia** is formed.

The solution is boiled when normal magnesium carbonate separates out.

$$2MgSO_4 + 2Na_2CO_3 + H_2O \longrightarrow \\ MgCO_3 \cdot Mg(OH)_2 + 2Na_2SO_4 + CO_2 \\ MgCO_3 \cdot Mg(OH)_2 + 3CO_2 + H_2O \longrightarrow 2Mg(HCO_3)_2 \\ Mg(HCO_3)_2 \longrightarrow MgCO_3 + CO_2 + H_2O$$

**Properties:** It is a white powder, insoluble in water. It dissolves readily in water containing excess of carbon dioxide.

$$MgCO_3 + CO_2 + H_2O \longrightarrow Mg(HCO_3)_2$$

It dissolves in acids forming salts with evolution of CQ2.

$$MgCO_3 + 2HCl \longrightarrow MgCl_2 + H_2O + CO_2$$

$$MgCO_3 + H_2SO_4 \longrightarrow MgSO_4 + H_2O + CO_2$$

On heating, it decomposes with evolution of CO2.

$$MgCO_3 \longrightarrow MgO + CO_2$$

It forms double carbonates with alkali carbonates.

$$MgCO_3 + Na_2CO_3 \longrightarrow Na_2Mg(CO_3)_2$$
  
Soluble

Uses: It is used:

(i) as a filler for paper, rubber and pigments.

- (ii) in the form of basic magnesium carbonate (magnesia alva) for making tooth powders, cosmetics and in medicine as antacid.
  - (iii) in the form of magnesite as a refractory material.
  - (iv) in glass manufacture, ceramics and inks.

## 4. Magnesium Chloride, MgCl<sub>2</sub>.6H<sub>2</sub>O

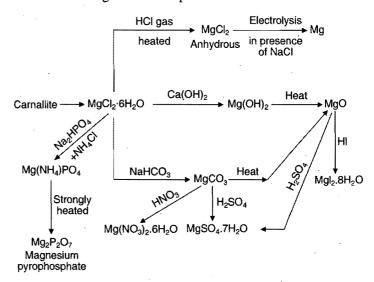

It occurs as mineral carnallite, KCl·MgCl<sub>2</sub>·6H<sub>2</sub>O and bischofite, MgCl<sub>2</sub>·H<sub>2</sub>O. It is found in sea water, mineral springs, etc.

**Preparation:** (a) It is extracted from carnallite mineral. The mineral is fused and cooled to 176°C when whole of KCl is deposited while MgCl<sub>2</sub>·6H<sub>2</sub>O remains in the fused state.

(b) It can also be obtained by dissolving Mg, MgO,Mg(OH)<sub>2</sub> or MgCO<sub>3</sub> in dilute hydrochloric acid.

The preparation of anhydrous magnesium chloride has already been described in the extraction of magnesium.

**Properties:** It is a colourless crystalline solid, highly deliquescent and highly soluble in water. It is the starting material for various magnesium compounds.

Uses: It is used:

- (i) for making Mg, MgO and other magnesium compounds.
- (ii) for making Sorel cement.
- (iii) in lubrication of cotton threads for spinning.
- (iv) in the preparation of **xylotite** which is used as covering for floors, laboratory tables, etc.

## ■ 5. Magnesium Sulphate, MgSO<sub>4</sub>·7H<sub>2</sub>O

It occurs in nature as minerals kieserite (MgSO<sub>4</sub>·H<sub>2</sub>O), epsom salt (MgSO<sub>4</sub>·7H<sub>2</sub>O) and kainite (KCl·MgSO<sub>4</sub>·3H<sub>2</sub>O).

**Preparation:** It is formed by reacting magnesite (MgCO<sub>3</sub>) or dolomite with dilute sulphuric acid.

$$\begin{array}{c} MgCO_3 + H_2SO_4 \rightarrow MgSO_4 + H_2O + CO_2 \\ MgCO_3 \cdot CaCO_3 + 2H_2SO_4 \rightarrow MgSO_4 + CaSO_4 + 2CO_2 + 2H_2O \\ \text{Dolomite} & \text{(Insoluble)} \end{array}$$

It is commercially prepared by boiling kieserite mineral in water. The crystals are obtained when the solution is cooled.

$$MgSO_4 \cdot H_2O + 6H_2O \longrightarrow MgSO_4 \cdot 7H_2O$$

**Properties:** It is a colourless crystalline compound, soluble in water. The crystals are efflorescent and bitter in taste. It is isomorphous with ZnSO<sub>4</sub>·7H<sub>2</sub>O. It forms double sulphates with alkali metal sulphates, K<sub>2</sub>SO<sub>4</sub>·MgSO<sub>4</sub>·6H<sub>2</sub>O (Schonite).

**Heating effect:** When heated to 150°C, it changes to monohydrate. On further heating, it becomes anhydrous at 200°C. On strong heating, it decomposes into MgO.

$$MgSO_4 \cdot 7H_2O \xrightarrow{150^{\circ}C} MgSO_4 \cdot H_2O \xrightarrow{200^{\circ}C} MgSO_4 \xrightarrow{Strong} MgO + SO_2 + \frac{1}{2}O_2$$

Magnesium sulphate is reduced by lampblack at 800°C.

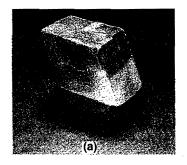

$$2MgSO_4 + C \longrightarrow 2MgO + 2SO_2 + CO_2$$

Uses: It is used:

- (a) as fertilizer.
- (b) as a laxative and analgesic in medicine.
- (c) as a filler for paper.
- (d) as a mordant in dyeing and tanning industry.
- (e) in the manufacture of paints and soaps and in fire-proofing fabrics.

### 7.7 CALCIUM

**Occurrence:** Calcium is a common element. In the combined state it is widely distributed in nature. Calcium is a rather abundant element specially in the form of its carbonate, CaCO<sub>3</sub>. This single compound takes on many different forms in nature appearing as chalk, limestone, marble, or crystalline **calcite** and **aragonite** under different geological circumstances.

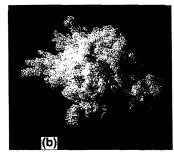

Fig. 7.4 Calcium carbonate (CaCO<sub>3</sub>) occurs in two crystalline forms: calcite (a) and aragonite (b). Limestone is an aggregate of small crystals

It is present in the earth's crust as silicates, which weather to give free calcium ion Ca<sup>++</sup>. The ion is about as abundant in sea water as magnesium ions. Calcium ion is an important nutrient for living organisms. Seashells are principally calcium carbonate. Corals are marine organisms that grow in colonies;

their calcium carbonate skeletons eventually form enormous coral reefs in warm water. It occurs as:

- (i) Carbonate—Limestone, marble, chalk, iceland spar and calcite as CaCO<sub>3</sub> and dolomite as MgCO<sub>3</sub>·CaCO<sub>3</sub>.
- (ii) Sulphate—Gypsum  $CaSO_4 \cdot 2H_2O$  and anhydrite  $CaSO_4$ .
  - (iii) Fluoride—Fluorspar CaF<sub>2</sub>,

Fluorapatite 3Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>·CaF<sub>2</sub>.

(iv) Phosphate—Phosphorite Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>.

It is present in natural water and causes hardness in water. It is an essential constituent of bones and teeth. Egg and seashells contain calcium carbonate.

**Extraction:** Calcium is obtained by electrolysis of a fused mass consisting six parts calcium chloride and one part calcium fluoride at about 700°C in an electrolytic cell made of graphite which acts as anode and a water cooled cathode of iron which is suspended from the top in the fused mass. On passing current, calcium is discharged at cathode. It gets solidified as cathode is water cooled.

 $CaCl_2 \Longrightarrow Ca^{2+} + 2Cl^{-}$ At anode:  $2Cl^{-} \longrightarrow Cl_2 + 2e$ At cathode:  $Ca^{2+} + 2e \longrightarrow Ca$ 

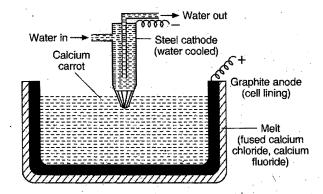

Fig. 7.5 Electrolytic extraction of calcium

Since metallic calcium is soluble in fused CaCl<sub>2</sub> at electrolysis temperature, it should be removed as soon as it is deposited. This is achieved by raising the cathode during electrolysis so that only the extreme tip of the deposited cathode remains in contact with the fused CaCl<sub>2</sub>.

[Note: Na or K is obtained by doing electrolysis of fused NaOH or KOH respectively but calcium cannot be obtained in the same manner as Ca(OH)<sub>2</sub> decomposes into CaO (quick lime) which is difficult to fuse.]

**Properties:** (i) It is a silvery white metal. It is malleable and ductile. It is good conductor of heat and electricity. Its specific gravity is 1.5.

(ii) On exposure, it is covered with a white powder consisting  $Ca(OH)_2$  and  $Ca_3N_2$ . It burns in air forming quick lime (CaO) and calcium nitride ( $Ca_3N_2$ ). It decomposes water evolving hydrogen.

$$2Ca + O_2 \longrightarrow 2CaO$$
  
 $3Ca + N_2 \longrightarrow Ca_3N_2$ 

Calcium reacts gently with water at room temperature to produce hydrogen and calcium hydroxide.

$$Ca + 2H_2O \longrightarrow Ca(OH)_2 + H_2$$

(iii) It has affinity for non-metals.

$$\begin{array}{c} 2\text{Ca} + \text{O}_2 \longrightarrow 2\text{CaO} \text{ (Calcium oxide)} \\ \text{Ca} + \text{H}_2 \stackrel{\text{Heat}}{\longrightarrow} \text{CaH}_2 \text{ (Calcium hydride)} \\ \text{Ca} + \text{Cl}_2 \stackrel{\text{Heat}}{\longrightarrow} \text{CaCl}_2 \text{ (Calcium chloride)} \\ \text{Ca} + 2\text{C} \stackrel{\text{Heat}}{\longrightarrow} \text{CaC}_2 \text{ (Calcium carbide)} \\ 3\text{Ca} + \text{N}_2 \stackrel{\text{Heat}}{\longrightarrow} \text{Ca}_3\text{N}_2 \text{ (Calcium nitride)} \\ \text{Ca} + \text{S} \longrightarrow \text{CaS} \text{ (Calcium sulphide)} \\ \end{array}$$

- (iv) It reacts violently with acids evolving hydrogen.
- (v) It reduces many metal oxides.

$$Cr_2O_3 + 3Ca \longrightarrow 2Cr + 3CaO$$
  
 $V_2O_5 + 5Ca \longrightarrow 2V + 5CaO$ 

(vi) When heated in atmosphere of CO<sub>2</sub>, it forms calcium carbide and calcium oxide.

$$5Ca + 2CO_2 \xrightarrow{Heat} CaC_2 + 4CaO$$

(vii) It dissolves in liquid ammonia. On evaporation, calcium ammoniate is formed.

$$Ca + 6NH_3 \longrightarrow Ca(NH_3)_6$$

On heating Ca(NH<sub>3</sub>)<sub>6</sub>, calcium amide is first formed which then changes into nitride.

$$Ca(NH_3)_6 \xrightarrow{\text{Heat}} Ca(NH_2)_2 + 4NH_3 \uparrow + H_2 \uparrow$$

$$3Ca(NH_2)_2 \xrightarrow{\text{Heat}} Ca_3N_2 + 4NH_3$$

Uses: (i) It is used as a deoxidiser for copper, cast iron and steel.

- (ii) It removes sulphur during petroleum refining.
- (iii) The metal is used in preference to sodium for the removal of last traces of water from alcohol as it does not react with alcohol.
  - (iv) It is also used as a reducing agent.

### COMPOUNDS OF CALCIUM

### 1. Quick Lime, CaO

Limestone, CaCO<sub>3</sub> found in nature is the starting material of almost all the compounds of calcium. Calcium oxide (CaO) is also called **quick lime** or **burnt lime**. It is obtained on large scale by heating limestone (CaCO<sub>3</sub>) in specially designed kilns (Fig. 7.6). The decomposition of calcium carbonate is a reversible process.

$$CaCO_3 \Longrightarrow CaO + CO_2$$

The reaction moves towards right hand direction if  $\rm CO_2$  formed is immediately removed from the kiln by allowing a blast of air to enter the kiln through fire boxes. The temperature for the decomposition of limestone should be near about  $\rm 1000^{\circ}C$  otherwise at higher temperature, the clay present in the limestone as impurity will react with it to form silicate.

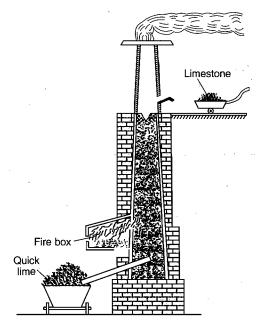

Fig. 7.6 Continuous vertical lime kiln with separate feed

Calcium oxide is a white amorphous solid. It is the cheapest form of alkali. It has a melting point of 2870 K. On exposure to atmosphere, it absorbs moisture and carbon dioxide.

$$CaO + H_2O \longrightarrow Ca(OH)_2$$
  
 $CaO + CO_2 \longrightarrow CaCO_3$ 

Being basic in nature, it combines with acidic oxides at high temperature.

$$\begin{array}{c} \text{CaO} + \text{SiO}_2 \longrightarrow \text{CaSiO}_3 \\ \text{6CaO} + \text{P}_4\text{O}_{10} \longrightarrow \text{2Ca}_3(\text{PO}_4)_2 \end{array}$$

### Slaked lime, $Ca(OH)_2(s)$ and lime water, $Ca(OH)_2(aq)$

Lime is sparingly soluble in water. When water is added to lime, a hissing sound is produced alongwith clouds of steam. In this process a large amount of heat energy is given out. The lime cracks with the formation of a powder called **slaked lime**  $[Ca(OH)_2]$ .

$$CaO + H_2O \longrightarrow Ca(OH)_2 + Heat energy$$
Ouick lime Slaked lime

The process is known as **slaking of lime**. The paste of lime in water is called **milk of lime** while the filtered and clear solution is known as **lime water**. Chemically both are Ca(OH)<sub>2</sub>.

$$\begin{array}{c} \text{Limestone} \xrightarrow{1000^{\circ}\text{C}} \text{Quick lime} \xrightarrow{\text{H}_2\text{O}} \text{Slaked lime} \\ & (\text{CaO}) & & [\text{Ca}(\text{OH})_2] \\ & & \downarrow \\ & & \text{Suspension} \longleftarrow \text{Suspended in water} \\ & & (\text{Milk of lime}) & & \downarrow \text{Filter} \\ & & \text{Ca}(\text{OH})_2 & & \text{Clear solution} \\ & & & (\text{Lime water}) \\ & & & \text{Ca}(\text{OH})_2 & & \\ \end{array}$$

**Properties:** It is a white amorphous powder and is sparingly soluble in water. When  $CO_2$  is passed through lime water, it turns milky due to the formation of calcium carbonate. On passing excess of  $CO_2$ , the precipitate dissolves forming calcium bicarbonate,  $Ca(HCO_3)_2$ .

$$\begin{array}{c} \text{Ca(OH)}_2 + \text{CO}_2 \longrightarrow \text{CaCO}_3 + \text{H}_2\text{O} \\ \text{Insoluble} \\ \text{CaCO}_3 + \text{H}_2\text{O} + \text{CO}_2 \longrightarrow \text{Ca(HCO}_3)_2 \\ \text{Soluble} \end{array}$$

This reaction, with its formation of milky precipitate, is the basis of a simple test for carbon dioxide.

It reacts with Cl<sub>2</sub> to form bleaching powder.

$$2Ca(OH)_2 + 2Cl_2 \longrightarrow \underbrace{CaCl_2 + Ca(OCl)_2}_{Bleaching powder} + 2H_2O$$
or
$$Ca(OH)_2 + Cl_2 \longrightarrow CaOCl_2 + H_2O$$
Bleaching powder

### **■** Uses

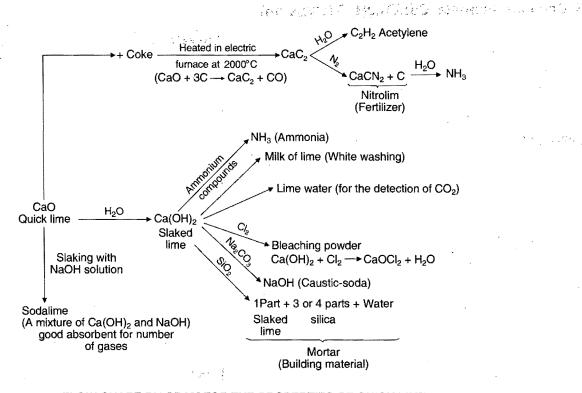

Quick lime is a commercial compound being used in various chemical industries as caustic soda, in the purification of sugar, manufacture of dye stuffs, bleaching powder, calcium carbide, calcium salts, mortar, cement, glass, etc.

Other uses of quick lime: (i) As it has high melting point (2600°C), it is used for furnace linings.

(ii) It is used as a basic flux in metallurgy as it combines with acidic impurities.

$$CaO + SiO_2 \longrightarrow CaSiO_3$$

- (iii) It is used as a disinfectant and germicide, as a drying agent for ammonia and alcohol.
- (iv) It is employed for the purification of coal gas and softening of water.
- (v) In the construction of buildings slaked lime is mixed with three to four times its weight of sand. The mixture is made into a thick paste with gradual addition of water. This paste is called **brick laying mortar** and is used in building construction. It sets to a hard mass by loss of water and gradual absorption of CO<sub>2</sub> from the air. Sometimes coal ash is mixed with lime instead of sand. A mortar obtained from hydraulic lime is called **hydraulic mortar**. It has greater strength and is used for construction of bridges.

Birth Small at a

### FLOW CHART DIAGRAM FOR THE PROPERTIES OF QUICK LIME

### 2. Calcium Carbonate, CaCO<sub>3</sub>

Limestone is one of the most important raw material for the chemicals and building industries. It is found in nature in huge quantities in various forms such as limestone, marble, chalk, etc.

Infact calcium carbonate is the second most abundant material in the earth's crust after silicate like clay, sand and sandstone.

Chalk is the softest form of calcium carbonate. Deposits of chalk have formed from the shells of dead sea creations that lived million of years ago. In some places the chalk covered with other rocks and put under great pressure. This changed the soft chalk into harder **rock-limestone**. In other places the chalk was under pressure and heat. This changed the soft chalk into **marble**, the hardest form of calcium carbonate.

It can be obtained by passing carbon dioxide through lime water or by adding sodium carbonate solution to CaCl<sub>2</sub>.

$$Ca(OH)_2 + CO_2 \longrightarrow CaCO_3 + H_2O$$
  
 $CaCl_2 + Na_2CO_3 \longrightarrow CaCO_3 + 2NaCl$ 

The precipitate of CaCO<sub>3</sub> thus obtained is known as **precipitated chalk**, a pure form of the finely divided compound.

It is a white powder, insoluble in water. It dissolves in presence of CO<sub>2</sub> due to formation of calcium bicarbonate.

$$CaCO_3 + H_2O + CO_2 \longrightarrow Ca(HCO_3)_2$$

- **Uses:** (i) Precipitated chalk is used in tooth pastes, tooth powders, and face powders, in medicine for indigestion, in adhesives in cosmetics and as a filler for paper.
  - (ii) Chalk is used in paints and distempers.
- (iii) Marble is used, (a) for building purposes, (b) in the production of CO<sub>2</sub> in laboratory.
- (iv) Limestone is used, (a) in the manufacture of quick lime, slaked lime, cement, washing soda and glass, (b) as a flux in the smelting of iron and lead ores.

### 3. Calcium Sulphate, CaSO<sub>4</sub>.2H<sub>2</sub>O (Gypsum)

It is found in nature as anhydride (CaSO<sub>4</sub>) and gypsum (CaSO<sub>4</sub>·2H<sub>2</sub>O).

It can be prepared by reacting any calcium salt with either sulphuric acid or a soluble sulphate.

$$CaCl_2 + H_2SO_4 \longrightarrow CaSO_4 + 2HCl$$
  
 $CaCl_2 + Na_2SO_4 \longrightarrow CaSO_4 + 2NaCl$ 

**Properties:** (i) It is a white crystalline solid. It is sparingly soluble in water and solubility decreases as temperature increases.

- (ii) It dissolves in dilute acids. It also dissolves in ammonium sulphate due to the formation of double sulphate,  $(NH_4)_2SO_4\cdot CaSO_4\cdot H_2O$ .
- (iii) Gypsum when heated first changes from monoclinic form to orthorhombic form without loss of water. At 120°C, it loses three-fourth of its water of crystallisation and forms hemihydrate, (2CaSO<sub>4</sub>·H<sub>2</sub>O) which is commonly known as **plaster of Paris.** At 200°C, it becomes anhydrous. The anhydrous form is known as **burnt plaster** or **dead plaster**.

$$\begin{split} 2[\text{CaSO}_4\text{·}2\text{H}_2\text{O}] &\xrightarrow{-120^{\circ}\text{C}} \quad [2\text{CaSO}_4\text{·}\text{H}_2\text{O}] + \quad 3\text{H}_2\text{O} \\ [2\text{CaSO}_4\text{·}\text{H}_2\text{O}] &\xrightarrow{-200^{\circ}\text{C}} \quad 2\text{CaSO}_4 + \quad \text{H}_2\text{O} \end{split}$$

When strongly heated, it decomposes to give calcium oxide.

$$\begin{array}{c} 2\text{CaSO}_4 \xrightarrow{\text{Strongly}} 2\text{CaO} + 2\text{SO}_2 + \text{O}_2 \\ \\ \text{CaSO}_4.2\text{H}_2\text{O} \xrightarrow{\text{Heated}} \text{CaSO}_4.2\text{H}_2\text{O} \xrightarrow{\text{120°C}} 2\text{CaSO}_4.\text{H}_2\text{O} \xrightarrow{\text{200°C}} \text{CaSO}_4 \\ \\ \text{Gypsum} \\ \text{(monoclinic)} & \text{(Orthorhombic)} & \text{Plaster of Paris} & \text{Anhydrous} \\ \\ \text{(burnt plaster)} & \text{Strongly} \\ \text{heated} & \text{O}_2 + \text{SO}_2 + \text{CaO} & \text{(lime)} \\ \end{array}$$

(iv) A suspension of gypsum when saturated with ammonia and carbon dioxide forms ammonium sulphate, a nitrogenous fertilizer.

$$2NH_3 + CaSO_4 + CO_2 + H_2O \longrightarrow (NH_4)_2SO_4 + CaCO_3$$

(v) When strongly heated with carbon, it forms calcium sulphide.

$$CaSO_4 + 4C \longrightarrow CaS + 4CO$$

Uses: It is used:

- (i) for the manufacture of plaster of Paris, cement, ammonium sulphate, sulphuric acid, etc.
  - (ii) for preparing blackboard chalk.
  - (iii) in anhydrous form as drying agent.

### 4. Plaster of Paris, 2CaSO<sub>4</sub>.H<sub>2</sub>O

(Calcium sulphate hemihydrate)

**Preparation:** It is obtained when gypsum, calcium sulphate dihydrate (CaSO<sub>4</sub>·2H<sub>2</sub>O), is heated at 120°C.

$$\begin{array}{cccc} 2[CaSO_4 \cdot 2H_2O] & \longrightarrow & 2CaSO_4 \cdot H_2O + 3H_2O \\ Calcium & sulphate & dihydrate & Calcium & sulphate \\ & & & & & hemihydrate \\ & & & & (Plaster of Paris) \end{array}$$

Properties: (i) Plaster of Paris is a white powder.

(ii) It has the property of setting to a hard mass when a paste with water is allowed to stand aside for sometime. Slight expansion occurs during the setting as water is absorbed to reform CaSO<sub>4</sub>·2H<sub>2</sub>O (gypsum). The setting process is exothermic. The process of setting takes place in two stages. In the first stage, there is conversion of plaster of Paris into orthorhombic form of gypsum (setting step) and in the second stage orthorhombic form changes into monoclinic form (hardening step).

$$2CaSO_4 \cdot H_2O \xrightarrow[H_2O]{Setting} CaSO_4 \cdot 2H_2O \xrightarrow[M_2O]{Hardening} CaSO_4 \cdot 2H_2O$$
Plaster of Paris Orthorhombic Monoclinic

The setting of plaster of Paris may be catalysed by sodium chloride while it is retarded by borax or alum. Addition of alum to plaster of Paris makes the setting very hard. The mixture is known as **Keene cement.** 

(iii) When plaster of Paris is heated at 200°C, it forms anhydrous calcium sulphate which is known as **dead plaster**. It has no setting property as it takes up water only very slowly.

Uses: It is used:

- (i) in surgery for setting broken or dislocated bones.
- (ii) in making casts for statues, toys, surgical instruments, etc.
  - (iii) in making casts in dentistry.
  - (iv) in making blackboard chalk.

### 3 4. Portland Cement

Portland cement is one of the most important building materials at the present time. It is used in the construction of buildings, roads, bridges, dams, etc. It was discovered, in 1824, by an English Mason, Joseph Aspdin who observed that when strongly heated mixture of limestone and clay was mixed with water and allowed to stand, it hardened to a stone-like mass which resembled portland rock—a famous building stone of England. Since then the name **portland cement** has been given to a mixture containing high percentage of lime with silica, iron oxide, alumina, etc.

Cement is a dirty greyish heavy powder containing calcium aluminates and silicates. The silicates and aluminates which form more than 90% of the cement are:

(i) Tricalcium silicate	3CaO·SiO <sub>2</sub>
(ii) Dicalcium silicate	2CaO⋅SiO <sub>2</sub>
(iii) Tricalcium aluminate	3CaO·Al <sub>2</sub> O <sub>3</sub>
(iv) Tetracalcium alumino-ferrite	4CaO·Al <sub>2</sub> O <sub>3</sub> ·Fe <sub>2</sub> O <sub>3</sub>

Of these, tricalcium silicate is most important.

**Composition of portland cement :** The approximate composition of portland cement is given below:

Oxide		Percentage by mass
Lime (Calcium oxide)	(CaO)	61.69%
Silica	(SiO <sub>2</sub> )	18.24%
Alumina	(Al <sub>2</sub> O <sub>3</sub> )	4-8%
Ferric oxide	$(Fe_2O_3)$	1-8%
Minor oxides	(MgO, Na <sub>2</sub> O, K <sub>2</sub> O, SO <sub>3</sub> )	2-4%

The essential constituents are lime, silica and alumina. These are generally kept in the following ratio:

$$\frac{\% \text{ Silica}}{\% \text{ Al}_2 \text{O}_3} = 2.5 - 4.0 ;$$

$$\frac{\% \text{ CaO}}{\% \text{ SiO}_2 + \% \text{ Al}_2 \text{O}_3 + \% \text{ Fe}_2 \text{O}_3} = 1.9 - 2.1$$

The cement containing no iron is white.

**Raw materials:** The important raw materials needed for the manufacture of cement are:

- (i) Limestone—This provides lime.
- (ii) Clay-This provides alumina and silica.
- (iii) Gypsum, (CaSO<sub>4</sub>·2H<sub>2</sub>O).

**Manufacture:** There are two processes in use for the manufacture of cement (i) Dry process and (ii) Wet process.

**Dry process:** The process is used when limestone is hard in nature. The limestone is first broken into small pieces. It is then mixed with clay in proper proportions. The mixture is finally pulverised to such an extent that it passes through a 100 mesh sieve. This homogeneous mixture is known as raw meal.

Wet process: The process is used when limestone and clay both are soft in nature. The clay is washed with water in wash mill to remove foreign materials like flint. The powdered limestone is mixed with clay paste in the ratio of 75% (limestone) and 25% (clay). The mixture is finely ground and made homogeneous. The homogeneous paste is known as slurry. It contains 40% (approximately) water.

**Calcination in rotary kiln:** This step is mainly responsible for the formation of cement. The heating of raw meal (dry process) or slurry (wet process) is done in a rotary kiln at a very high temperature 1400–1600°C. The kiln consists of a long cylinder 6 to 10 feet in diameter and 100 to 250 feet in length. It is made of steel and lined inside with fire bricks (Fig.7.7).

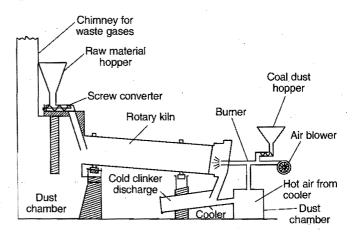

Fig. 7.7

The charge (raw meal or slurry) is introduced in the kiln with the help of a screw conveyer. It moves forward with the rotary motion given to the kiln. The charge is heated by burning coal dust which is blown in from the other side with the help of a blower. In the upper portion of the kiln, the temperature is about 750°C where whole of moisture is eliminated. In the middle portion, the temperature is about 1000°C. The limestone decomposes with evolution of CO<sub>2</sub>. At the lower end, the temperature is 1600°C. The following reactions occur:

$$\begin{array}{c} \text{CaCO}_{3} \longrightarrow \text{CaO} + \text{CO}_{2} \\ 2\text{CaO} + \text{SiO}_{2} \longrightarrow 2\text{CaO} \cdot \text{SiO}_{2} \\ 3\text{CaO} + \text{SiO}_{2} \longrightarrow 3\text{CaO} \cdot \text{SiO}_{2} \\ 3\text{CaO} + \text{Al}_{2}\text{O}_{3} \longrightarrow 3\text{CaO} \cdot \text{Al}_{2}\text{O}_{3} \\ 4\text{CaO} + \text{Al}_{2}\text{O}_{3} + \text{Fe}_{2}\text{O}_{3} \longrightarrow 4\text{CaO} \cdot \text{Al}_{2}\text{O}_{3} \cdot \text{Fe}_{2}\text{O}_{3} \end{array}$$

The product formed is technically called as clinker. It is cooled and mixed with 2 or 3% of its weight of gypsum. It is then ground to an exceedingly fine powder. The powder is packed in air tight bags.

The purpose of the addition of gypsum (CaSO<sub>4</sub>·2H<sub>2</sub>O) is to increase the setting time of the cement.

**Setting of cement:** When cement is mixed with water and left as such for some time, it becomes a hard mass. This is known as setting of cement. The exact mechanism of this setting process is not known. It is believed that various aluminates and silicates present in the cement form hydrates with water which separate in the form of gel.

$$3\text{CaO·Al}_2\text{O}_3 + 6\text{H}_2\text{O} \xrightarrow{\text{Hydration}} 3\text{CaO·Al}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$$
Colloidal gel

$$\begin{array}{c} 2\text{CaO·SiO}_2 + x\text{H}_2\text{O} \xrightarrow{\text{Hydration}} 2\text{CaO·SiO}_2 \cdot x\text{H}_2\text{O} \\ & \text{Colloidal gel} \\ 4\text{CaO·Al}_2\text{O}_3 \cdot \text{Fe}_2\text{O}_3 + 6\text{H}_2\text{O} \xrightarrow{\text{Hydration}} \\ & 3\text{CaO·Al}_2\text{O}_3 \cdot 6\text{H}_2\text{O} + \text{Fe}_2\text{O}_3 \cdot \text{CaO} \\ & \text{Colloidal gel} \end{array}$$

At the same time some Ca(OH)<sub>2</sub> and Al(OH)<sub>3</sub> are formed as precipitates due to hydrolysis.

$$3\text{CaO·SiO}_2 + \text{H}_2\text{O} \xrightarrow{\text{Hydrolysis}} \text{Ca(OH)}_2 + 2\text{CaO·SiO}_2$$
  
 $3\text{CaO·Al}_2\text{O}_3 + 6\text{H}_2\text{O} \xrightarrow{\text{Hydrolysis}} 3\text{Ca(OH)}_2 + 2\text{Al(OH)}_3$ 

Gypsum combines with tricalcium aluminate to form calcium sulpho-aluminate.

$$3\text{CaO} \cdot \text{A1}_2\text{O}_3 + 3\text{CaSO}_4 + 2\text{H}_2\text{O} \rightarrow 3\text{CaO} \cdot \text{A1}_2\text{O}_3 \cdot 3\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$$

This reaction slows down the setting.

The gels formed start losing water partly by evaporation and partly by forming hydrates with unhydrated constituents. This results in the formation of a hard mass. Ca(OH)<sub>2</sub> binds the particles of calcium silicate together, while Al(OH)<sub>3</sub> fills the interstices resulting in hardening the mass.

Setting of cement is an exothermic process. Hence, cement structures have to be cooled during setting by sprinkling water.

Concrete: A mixture of cement, sand, gravel or small pieces of stone and water is known as concrete. It sets to an exceedingly hard structure. It is mainly used for construction of floors. If the cement concrete is filled in and around a wire netting or skeleton of iron rods and allowed to set, the resulting structure is known as reinforced concrete. These structures have great strength and are used for construction of roofs, bridges, etc.

Cement industry in India: Cement industry was started in India with the establishment of first factory in 1904 in Tamil Nadu. India is, at present, one of top ten cement producing countries in the world. There are about 60 cement factories in public and private sectors producing near about 2.5 crore tons cement annually.

### 7.8 COMPOUNDS OF BARIUM

**Preparation:** Barium is found in nature mainly in the form of sulphate, BaSO<sub>4</sub>, called barytes or heavy spar. Barytes is a source for the preparation of various compounds of barium which are of industrial importance.

The natural barytes is ground, mixed with coke and the mixture is heated in a rotary kiln, barium sulphate is reduced to barium sulphide.

$$BaSO_4 + 4C \longrightarrow BaS + 4CO$$

The kiln clinker is extracted with water. The solution is treated with sodium carbonate to precipitate barium carbonate.

$$BaS + Na_2CO_3 \longrightarrow BaCO_3 + Na_2S$$

Barium carbonate is used further for barium compounds and the filtrate is concentrated for sodium sulphide crystals, Na<sub>2</sub>S·9H<sub>2</sub>O. Barium carbonate cannot be decomposed by heat. It is mixed with carbon and heated in a furnace to form barium oxide.

$$BaCO_3 + C \longrightarrow BaO + 2CO$$

The barium oxide when heated at 540°C in purified air is oxidised to barium peroxide.

$$2BaO + O_2 \xrightarrow{540^{\circ}C} 2BaO_2$$

Barium carbonate is used for the preparation of other salts as acetate, chloride and nitrate.

$$BaCO_3 + 2CH_3COOH \longrightarrow (CH_3COO)_2Ba + CO_2 + H_2O$$

$$BaCO_3 + 2HC1 \longrightarrow BaCl_2 + CO_2 + H_2O$$

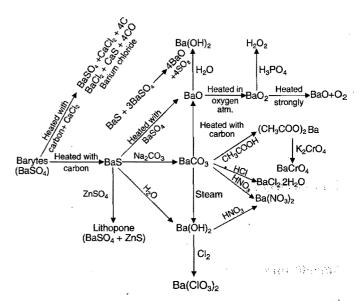

$$BaCO_3 + 2HNO_3 \longrightarrow Ba(NO_3)_2 + CO_2 + H_2O$$

When barium carbonate is heated to red heat in a current of steam, barium hydroxide is formed with evolution of carbon dioxide.

$$BaCO_3 + H_2O \longrightarrow Ba(OH)_2 + CO_2$$

Barium chlorate, Ba(ClO<sub>3</sub>)<sub>2</sub> can be prepared by the action of chlorine on barium hydroxide solution (hot and concentrated). Barium chlorate being less soluble, separates out.

$$6Ba(OH)_2 + 6Cl_2 \longrightarrow Ba(ClO_3)_2 + 5BaCl_2 + 6H_2O$$

Uses: Uses of barium compounds:

- (i) BaO is an excellent drying agent especially for organic bases like pyridine.
- (ii)  $BaO_2$  is used in the preparation of  $H_2O_2$  and ignition mixture used in thermite process. It is also used as an oxidising agent.
- (iii) Ba(OH)<sub>2</sub> is used for the preparation of a standard alkali solution for titrating acids.
- (iv) BaCl<sub>2</sub> is used as a laboratory reagent for the test of sulphate radical.
- (v) Ba(ClO<sub>3</sub>)<sub>2</sub> is used for producing green fire and for the preparation of chloric acid.

- (vi) BaSO<sub>4</sub> is used as a white pigment either as such or mixed with zinc sulphide under the name of lithopone (BaSO<sub>4</sub> + ZnS). It is also used as a filler in rubber and paper industry.
- (vii) Barium titanate (BaTiO<sub>3</sub>) is **piezoelectric**, which means that it becomes electrically charged when it is mechanically distorted. This property leads to its use for underwater sound detection, in which a mechanical vibration is converted into an electrical signal.

(viii) When barium hydroxide octahydrate.  $Ba(OH)_2 \cdot 8H_2O$ , and ammonium thiocyanate,  $NH_4SCN$ , are ground together, one moderately, endothermic reaction takes place. An endothermic reaction absorbs heat. The reaction mixture becomes so cold that moisture from the air forms a layer of frost on the outside of the beaker.

 $Ba(OH)_2 \cdot 8H_2O + 2NH_4SCN \longrightarrow Ba(SCN)_2 + 2NH_3 + 10H_2O - Heat$ 

### SOME SOLVED PROBLEMS

### **Example 1.** Explain the following:

(i) Beryllium chloride fumes in air.

or

Beryllium chloride is acidic when dissolved in water.

- (ii) Barium ion,  $Ba^{2+}$ , is poisonous, yet  $BaSO_4$  is given to patients prior to taking stomach X-ray. Why is it safe to use  $BaSO_4$  internally?
- (iii) Alkaline alkali metals.
  - (iv) Alkaline earth metal salts are diamagnetic in nature.
  - (v) Magnesium oxide is used as a refractory material.

#### Solution:

(i) BeCl<sub>2</sub> undergoes hydrolysis being a salt of a weak base and a strong acid. Fumes of HCl gas are evolved in presence of moisture in atmosphere.

or

When dissolved in water, strong acid HCl is formed in solution.

$$BeCl_2 + 2H_2O \longrightarrow Be(OH)_2 + 2HCl$$

- (ii) BaSO<sub>4</sub> is extremely insoluble and does not pass from digestive system into the circulatory system.
- (iii) Alkaline earth metals have high values of atomisation and ionisation potentials in comparison to alkali metals. The oxidation potentials have lower values than alkali metals and hence, alkaline earth metals are weaker reducing agents.
- (iv) The ions of alkaline earth metals,  $M^{2+}$ , have inert gas configuration, *i.e.*, all the orbitals are doubly occupied.

Hence, alkaline earth metal salts are diamagnetic in nature.

(v) MgO has very high melting point and does not decompose as its lattice energy is very high. It is, thus, used as refractory material.

### **Example 2.** Give reasons for the following:

- (i) Solubility of the sulphates of alkaline earth metals decreases from top to bottom in the group.
- (ii) Solubility of hydroxides of alkaline earth metals increases from top to bottom in the group.
- (iii) Sodium chloride is added during electrolysis of fused anhydrous MgCl<sub>2</sub>.
- (iv) Alkaline earth metal salts are less soluble than the corresponding alkali metal salts.

- (v) Beryllium oxide is insoluble but BaO is soluble.
- (vi) BeCl<sub>2</sub> can be easily hydrolysed.

(TTT 1000

### **Solution:**

- (i) Lattice energies of the sulphates are nearly the same. The size of sulphate ion is large and small changes in cation size do not affect the lattice energies. However, the hydration energies decrease from Be<sup>2+</sup> to Ba<sup>2+</sup>. Hence, solubility of sulphates decreases from top to bottom.
- (ii) Lattice energies of hydroxides decrease as the size of cation increases. It overcomes the effect of decrease in hydration energy and hence, the solubility of hydroxides increases from top to bottom.
- (iii) NaCl is added as to lower the fusion temperature of MgCl<sub>2</sub> and to make the mixture as good conductor of electricity.
- (iv) Lattice energies of the salts of alkaline earth metals are very high in comparison to alkali metal salts. High lattice energies are responsible for low solubility.
- (v) The lattice energy of BeO is higher than BaO due to small size of Be<sup>2+</sup> ion. The other reason may be that BeO is covalent and polymeric while BaO is ionic in nature.
- (vi) The Be<sup>2+</sup> ions are easily hydrated because of high charge size ratio. The hydrolysis occurs because Be—O bond is very strong.

**Example 3.** Give the names and formula of the compounds indicated in the following statements:

- (a) A compound of Ca used in setting fractured bones.
- (b) A compound of Mg, S, O and H used as a purgative in medicine.
- (c) A compound of Ca and C used for the production of acetylene.
  - (d) A compound of Ca, C and N used as a fertilizer.
- (e) A triatomic compound which on treatment with water gives  $H_2$ .

Solution: (a) Plaster of Paris, 2CaSO<sub>4</sub>·H<sub>2</sub>O

- (b) Magnesium sulphate, MgSO<sub>4</sub>·7H<sub>2</sub>O
- (c) Calcium carbide, CaC<sub>2</sub>

$$CaC_2 + 2H_2O \longrightarrow Ca(OH)_2 + C_2H_2$$

- (d) Calcium cyanamide (nitrolim), CaCN<sub>2</sub>
- (e) Calcium hydride (hydrolith), CaH2

**Example 4.** 0.3 g of magnesium ribbon was placed in a crucible and heated with the lid on until the magnesium began to burn brilliantly. At the end of the experiment there was 0.45 g of the white powder left. Show that this result does not agree with the equation,

$$2Mg(s) + O_2(g) \longrightarrow 2MgO(s)$$

What might have gone wrong?

**Solution:** The given equation is,

$$2Mg(s) + O_2(g) \longrightarrow 2MgO(s)$$
  
2×24=48 g 2×(24+16)=80 g

The equation shows that 48 g of magnesium should give 80 g of magnesium oxide. Therefore, 0.3 g of magnesium should give  $\frac{80 \times 0.3}{48} = 0.5$  g of the oxide. The actual amount of MgO obtained is 0.45 g. Perhaps some of the oxide escaped as smoke or the magnesium did not react completely or the magnesium may have combined with nitrogen to make magnesium nitride instead.

**Example 5.** Beryllium gives a compound with the following percentage composition: Be, 6.1%; N, 37.8%; Cl, 48%; H, 8.1%. One mole of the compound had a mass of 148 g. M(Be) = 9 g  $mol^{-1}$ .

- (i) What is the molecular formula of the compound?
- (ii) In water, 1 mole of the compound reacts with 2 moles of  $Ag^+$  ions.

Suggest a structural formula for the compound.

#### Solution:

Determination of empirical formula

Element	Percentage	At. mass	Relative number atom	Simplest ratio
Be	6.1	9.0	$\frac{6.1}{9} = 0.68$	$\frac{0.68}{0.68} = 1$
N	37.8	14.0	$\frac{37.8}{14} = 2.7$	$\frac{2.7}{0.68} = 4$
Cl	48.0	35.5	$\frac{48.0}{35.5} = 1.35$	$\frac{1.35}{0.68} = 2$
Н	8.1	1.0	$\frac{8.1}{1.0} = 8.1$	$\frac{8.1}{0.68} = 12$

Empirical formula =  $BeN_4Cl_2H_{12}$ 

Empirical mass =  $9 + 4 \times 14 + 2 \times 35.5 + 12 \times 1 = 148$ Hence, molecular formula = BeN<sub>4</sub>Cl<sub>2</sub>H<sub>12</sub>

The reaction with silver ions suggests that 2 chlorine atoms are present as chloride ions. Thus, the structural formula of the compound is [Be(NH<sub>3</sub>)<sub>4</sub>]Cl<sub>2</sub>.

**Example 6.** Compare the thermal stability of the following compounds of the alkali metals with those of alkaline earth metals: (a) nitrates (b) carbonates (c) sulphates.

#### **Solution:**

(a) Nitrates: Nitrates of both alkali and alkaline earth metals decompose on heating.

Nitrates of alkali metals decompose to form metal nitrites and  $O_2$ .

$$2MNO_3 \longrightarrow 2MNO_2 + O_2$$
 (M = Na, K, Rb or Cs)

Nitrates of alkaline earth metals decompose forming corresponding metal oxides, NO<sub>2</sub> and O<sub>2</sub>.

$$M(NO_3)_2 \longrightarrow MO + 2NO_2 + O_2$$
  
(M = Be, Mg, Ca, Sr or Ba)

Lithium nitrate behaves like Mg(NO<sub>3</sub>)<sub>2</sub> due to diagonal relationship.

$$4\text{LiNO}_3 \longrightarrow 2\text{Li}_2\text{O} + 4\text{NO}_2 + \text{O}_2$$

**(b) Carbonates:** Carbonates of alkali metals are stable and do not decomposes on heating.

Carbonates of alkaline earth metals decompose on heating. However, stability increases as the decomposition temperature indicate which increase from BeCO<sub>3</sub> to BaCO<sub>3</sub>.

$$MCO_3 \longrightarrow MO + CO_2$$

Li<sub>2</sub>CO<sub>3</sub> like MgCO<sub>3</sub> also decomposes on heating.

$$\text{Li}_2\text{CO}_3 \longrightarrow \text{Li}_2\text{O} + \text{CO}_2$$

**(c) Sulphates:** Sulphates of alkali metals are stable and do not decompose on heating.

Sulphates of alkaline earth metals decompose on heating into oxides and SO<sub>3</sub>.

$$MSO_4 \longrightarrow MO + SO_3$$

The stability increases as the temperature of decomposition of these sulphates increase gradually.

Li<sub>2</sub>SO<sub>4</sub> like MgSO<sub>4</sub> also decomposes on heating.

**Example 7.** (a) Why  $BaSO_4$  is insoluble whereas  $BeSO_4$  is soluble in water?

(b) What is the hybrid state of Be in BeCl<sub>2</sub>? What will be the change in the hybrid state of BeCl<sub>2</sub> in the solid state?

[C.B.S.E. (P.M.T.) 2005]

#### **Solution:**

- (a) The lattice energy of BaSO<sub>4</sub> is much more than its hydration energy and hence it is insoluble in water. The hydration energy of BeSO<sub>4</sub> is much higher than its lattice energy because of small size of Be<sup>2+</sup> ions. Hence, it is soluble in water.
- (b) In the vapour state,  $BeCl_2$  is linear as Be is sp hybridized. However, in solid state,  $BeCl_2$  is polymeric. In the polymeric structure, each Be has two covalent and two co-ordinate bonds, *i.e.*, Be is  $sp^3$  hybridized.
- **Example 8.** (a)  $Mg_3N_2$  when reacted with water gives off ammonia but HCl is not obtained when  $MgCl_2$  reacts with water at room temperature. Give reason.
- (b) Chlorination of calcium hydroxide produces bleaching powder. Write the chemical equation.

#### **Solution:**

(a) Mg<sub>3</sub>N<sub>2</sub> is a salt of a strong base, Mg(OH)<sub>2</sub>, and a weak acid (NH<sub>3</sub>) and hence gets hydrolysed to give NH<sub>3</sub>.

$$Mg_3N_2 + 6H_2O \longrightarrow 3Mg(OH)_2 + 2NH_3$$

MgCl<sub>2</sub> is a salt of a strong base and a strong acid (HCl) and hence, its hydrolysis does not occur.

$$\begin{array}{c} \text{(b)} \quad \text{Ca(OH)}_2 + \text{Cl}_2 & \longrightarrow \text{Ca(OCl)Cl} + \text{H}_2\text{O} \\ & \text{Slaked} & \text{Bleaching} \\ & \text{lime} & \text{powder} \end{array}$$

Bleaching powder is also considered as a mixture of Ca(OCl)<sub>2</sub>, CaCl<sub>2</sub> and Ca(OH)<sub>2</sub>.

$$3Ca(OH)_2 + 2Cl_2 \longrightarrow Ca(OCl)_2 \cdot Ca(OH)_2 \cdot CaCl_2 \cdot 2H_2O$$
Bleaching powder

**Example 9.** Draw the structure of (i) BeCl<sub>2</sub> (vapour state) (ii) BeCl<sub>2</sub> (solid).

#### Solution.

In vapour state, it has chlorobridged dimer structure which dissociates into linear monomer at 1000°C.

In the solid state, it has a polymeric structure with dichlorobridges in which a halogen atom bonded to one beryllium atom uses a lone pair of electrons to form a co-ordinate bond to other beryllium atom.

**Example 10.** (a) Halides of Be dissolve in organic solvents while those of barium do not. Why is it so?

- (b) What is the difference between milk of lime and lime water?
- (c) Why is calcium preferred over sodium to remove last traces of moisture from alcohol?

### Solution.

- (a) Halides of beryllium are covalent due to small size of Be<sup>2+</sup> ion while halides of barium are ionic.
- (b) The suspension of Ca(OH)<sub>2</sub> in water is termed milk of lime while clear solution of Ca(OH)<sub>2</sub> is called lime water.
- (c) Both Ca and Na can remove moisture from alcohol but sodium reacts with alcohol also readily. Calcium reacts with alcohol very slowly.

**Example 11.** (a) State any one reason for alkaline earth metals, why they have a greater tendency to form complexes than alkali metals.

(b) Alkaline earth metals cannot be obtained by chemical reduction.

#### Solution.

- (a) Alkaline earth metal cations have smaller size and higher charge in comparison to alkali metal cations. These factors are responsible for greater tendency to form complexes.
- (b) Alkaline earth metals cannot be obtained by chemical reduction as they themselves are stronger reducing agents than common reducing agents. With carbon, they form carbides.

### Example 12. How would you explain?

- (i) BeO is insoluble but BeSO<sub>4</sub> is soluble in water.
- (ii) BaO is soluble but BaSO<sub>4</sub> is insoluble in water.
- (iii) What is the difference between milk of lime and lime water?
  - (iv) Why do halides and hydrides of beryllium polymerise? Solution.
- (i) The lattice enthalpy of BeO is higher than its hydration enthalpy and thus it is insoluble in water. BeSO<sub>4</sub> on the other hand has lower lattice enthalpy than hydration enthalpy and hence it is soluble in water. The lower lattice enthalpy is due to bigger size of  $SO_4^{2-}$  ion.
- (ii) In BaO, the lattice enthalpy is less than hydration enthalpy and thus it is soluble in water while in BaSO<sub>4</sub>, the lattice enthalpy is more than hydration enthalpy and hence, it is insoluble in water.
- (iii) Both milk of lime and lime water are chemically same *i.e.*, Ca(OH)<sub>2</sub>. The suspension of slaked lime in water is called milk of lime while clear solution of slaked lime is know as lime water. Slaked lime is sparingly soluble in water.
- (iv) The monomeric molecules BeH<sub>2</sub> and BeCl<sub>2</sub> formed with normal bonds will result in only four electrons in the outer shell of beryllium atom making it electron deficient. By polymerising, each atom shares its electrons with several neighbours and receives a share in their electrons making the situation more favourable. Therefore, the halides and hydrides of Be polymerise.

### O

### SUMMARY AND IMPORTANT POINTS TO REMEMBER

- IIA group of the periodic table consists of six elementsberyllium, magnesium, calcium, strontium, barium and radium. These elements are called alkaline earth metals. The oxides of these elements are alkaline and exist in the earth-so they are called alkaline earth metals. The last member is radioactive.
- The first element, beryllium, is less active than other elements and shows abnormal properties like lithium in IA group on account of small atomic and ionic size and high electronegativity. It shows resemblance with aluminium (an element of IIIrd group), i.e., diagonal relationship.
- 3. The outermost shell of these elements has two electrons, *i.e.*,  $ns^2$  configuration. Because of their similarity in electronic configuration [noble gas]  $ns^2$ , they are included in the same group and closely resemble each other. There is a gradual gradation in their properties from top to bottom as atomic number increases.

#### 4. Physical characteristics

(i) All are silvery white metals. They are soft but harder than alkali metals. Softness increases from Be to Ba.

16. Plaster of Paris has the property of setting to a hard mass—CaSO<sub>4</sub>·2H<sub>2</sub>O, slight expansion occurs during setting. Addition of alum to plaster of Paris makes the setting very hard. The mixture is known as **Keene cement.** 

Plaster of Paris is used for setting broken or dislocated bones, casts for statues, toys and in dentistry.

When plaster of Paris is heated at 200°C, it forms anhydrous calcium sulphate which is known as **dead plaster**. It has no setting property.

- 17. (a) Anhydrous CaCl<sub>2</sub> is a good drying agent. It cannot be used for drying ammonia and alcohol as it forms addition products with them.
  - (b) Hydroxyapatite, Ca<sub>5</sub>(PO<sub>4</sub>)<sub>3</sub> OH is the main component of tooth enamel. Cavities are formed when acids decompose this enamel. This can be prevented by converting the hydroxyapatite to more resistant enamel–fluorapatite, Ca<sub>5</sub>(PO<sub>4</sub>)<sub>3</sub>·F.
  - (c) Most of the kidney stones consist of calcium oxalate, CaC<sub>2</sub>O<sub>4</sub>·H<sub>2</sub>O.
  - (d) Mg<sup>2+</sup> and Ca<sup>2+</sup> ions present in water are responsible for hardness of water.
  - (e) CaC<sub>2</sub> is obtained by heating a mixture of CaO and carbon. It reacts with nitrogen forming nitrolim, used as a fertilizer.

$$CaC_2 + N_2 \longrightarrow \underbrace{CaCN_2 + C}_{\text{nitrolim}}$$

18. Cement is an important building material. The average composition of portland cement is: CaO 61.5%, SiO<sub>2</sub> 22.5%, Al<sub>2</sub>O<sub>3</sub> 7.5%. Cement is a dirty greyish heavy powder containing calcium silicates and aluminates. Cement consists of:

Tricalcium silicate 3CaO·SiO<sub>2</sub>

Dicalcium silicate 2CaO·SiO<sub>2</sub>

Tricalcium aluminate 3CaO · Al<sub>2</sub>O<sub>3</sub>

Tetracalcium alumino-ferrite 4CaO·Al<sub>2</sub>O<sub>3</sub>·Fe<sub>2</sub>O<sub>3</sub>

For manufacture, limestone and clay are fused at 1400–1600°C in a rotary kiln. The product obtained is called **clinker.** It is mixed with 2–3% gypsum and powdered.

When cement is mixed with water, it sets to a hard mass, this is called setting. Setting is an exothermic process. During setting hydration occurs.

- **19.** Be shows diagonal relationship with aluminium, the second element of III A group.
  - (a) The polarising power of Be<sup>2+</sup> and Al<sup>3+</sup> ions is high. Consequently the compounds are covalent.
  - (b) The electronegativity of both the elements is nearly the same.
  - (c) Both do not decompose water.
  - (d) Both become passive when treated with conc. HNO<sub>3</sub>.
  - (e) Both dissolve in caustic alkalies liberating H<sub>2</sub>.
  - (f) The oxides and hydroxides are amphoteric.
  - (g) Be<sub>2</sub>C and Al<sub>4</sub>C<sub>3</sub> on hydrolysis evolve CH<sub>4</sub>.
  - (h) Both combine with nitrogen.
  - (i) Both form polymeric hydrides.
  - (j) Halides are formed in similar fashion.

Oxide + C + 
$$Cl_2 \longrightarrow Chloride$$

Halides except fluorides are covalent in nature.

**20.** Solutions of beryllium salts are acidic and dissolve appreciable quantities of Be(OH)<sub>2</sub>. In alkali solution [Be(OH)<sub>4</sub>]<sup>2-</sup> is formed.

$$\begin{split} \left[ \text{Be}(\text{H}_2\text{O})_4 \right]^{2+} & \rightleftharpoons \left[ \text{Be}(\text{H}_2\text{O})_3(\text{OH}) \right]^+ + \text{H}^+ \\ \left[ \text{Be}(\text{H}_2\text{O})_3(\text{OH}) \right]^+ & \rightleftharpoons \left[ \text{Be}(\text{H}_2\text{O})_2(\text{OH})_2 \right] + \text{H}^+ \\ \left[ \text{Be}(\text{H}_2\text{O})_2(\text{OH})_2 \right] & \rightleftharpoons \left[ \text{Be}(\text{H}_2\text{O})(\text{OH})_3 \right]^- + \text{H}^+ \\ \left[ \text{Be}(\text{H}_2\text{O})(\text{OH})_3 \right]^- & \rightleftharpoons \left[ \text{Be}(\text{OH})_4 \right]^{2-} + \text{H}^+ \end{split}$$

- 21. SrCO<sub>3</sub> is used in the manufacture of glass for colour TV picture tube.
- 22. BaSO<sub>4</sub> is used in medicine as a contrast medium for stomach and intestinal X-rays.

### - • • • - PRACTICE PROBLEMS - • • • -

### **■** Subjective Type Questions

#### 1. Give reasons:

- (a) Halides of Beryllium are soluble in organic solvents.
- (b) Beryllium chloride fumes in moist air.
- (c) CaCO<sub>3</sub> dissolves in water in excess of CO<sub>2</sub>.
- (d) A piece of burning magnesium ribbon continues to burn in SO<sub>2</sub>.
- (e) CaCl<sub>2</sub> cannot be used for drying ammonia.

### 2. Answer the following:

- (i) Name three natural forms of calcium carbonate.
- (ii) Which alkaline earth metal is found in abundance in earth's crust?
- (iii) Name the alkaline earth metal which is radioactive in nature.
- (iv) Name the natural carbonate mineral in which both calcium and magnesium are present.

- (v) Name two ores of magnesium.
- (vi) Which element of alkaline earth metal has least density?
- (a) Name the element which is invariable bivalent and whose oxide is soluble in excess of NaOH.
  - (b) Name the alkaline earth metal which shows resemblance with aluminium.
  - (c) Name the alkaline metal hydroxide which is amphoteric.
  - (d) Which elements of group 2 do not give characteristic flame colouration?
  - (e) Which out of Mg<sup>2+</sup>, Ba<sup>2+</sup>, Ca<sup>2+</sup> has maximum ionic mobility?
  - (f) What is dead burnt plaster?
  - (g) What is fly ash?
- 4. Give the name and formula of the compounds as indicated in the following statements:
  - A compound of calcium and hydrogen which is used as a portable source of hydrogen for filling balloons.

- (ii) A compound of Mg, O, Cl and H used as a cement for joining cracked teeth.
- (iii) A compound of Ca, O, Cl and H used as a germicide.
- (iv) A compound of Mg, Cl and O used as drying agent.
- (v) A compound of Ca and O which when heated in oxycoal gas flame gives lime light.
- 5. How do the following properties of the alkaline earth metals change when we move from Be to Ba?
  - Size of the atoms and ions
  - (ii) Ionisation energies
- (iii) Electronegativity
- (iv) Hardness
- (v) Oxidation potential
- (vi) Basic character of hydroxides
- (vii) Solubility of hydroxides (viii) Solubility of sulphates
- (ix) Stability of carbonates
- (x) Reducing nature
- **6.** Write the chemical formula of the following:
  - (a) Quick lime
- (b) Slaked lime
- (c) Anhydrone

- (d) Baryta water
- (e) Marble
- (f) Anhydrite

- (g) Gypsum
- (h) Plaster of Paris
- (i) Asbestos

- (j) Hydrolith.
- 7. Write formulae of the following minerals:
  - (i) Beryl, (ii) Magnesite, (iii) Kieserite, (iv) Witherite,
  - (v) Celestine, (vi) Epsom salt, (vii) Chrysoberyl, (viii) Baryta,
  - (ix) Strontianite, (x) Fluorspar.
- **8.** What happen when the following are heated?
  - (i) Hydrated magnesium chloride, (ii) Gypsum, (iii) Bicarbonates of alkaline earth metals, (iv) Epsom salt, (v) Barium nitrate.
- **9.** What is the action of water on the following?
  - (i) Beryllium carbide, (ii) Calcium carbide, (iii) Calcium nitride, (iv) Calcium cyanamide, (v) Hydrolith.
- 10. What happens when?
  - (i) Magnesium is burnt in air and the products treated
  - (ii) Water is added, to CaC<sub>2</sub> and the resulting gas is passed through dilute H<sub>2</sub>SO<sub>4</sub> containing HgSO<sub>4</sub>.
  - (iii) Hydrated magnesium chloride is heated in presence of ammonium chloride.
  - (iv) FeCl<sub>3</sub> is treated with magnesium.
  - (v) NH<sub>4</sub>Cl is heated with magnesium.
  - (vi) CO<sub>2</sub> is passed through lime water.
  - (vii) SO<sub>2</sub> is passed through lime water.
  - (viii) Cl<sub>2</sub> reacts with slaked lime under different conditions.
- 11. Complete and balance the following equations:
  - (a)
  - (b)
  - (c)
  - $BaCO_3 + H_2O(steam) \xrightarrow{Heat} \dots + CO_2$
  - (e)  $BeCl_2 + LiAlH_4 \longrightarrow ..... + LiCl + .....$
  - (f) CaO + C  $\xrightarrow{\text{High temp.}} \dots + \text{CO} \xrightarrow{\text{High temp.}} \dots + \dots$
- 12. How will you prepare the following? Give chemical equations also:
  - (a) Bleaching powder from CaCO<sub>3</sub>.
  - (b) Calcium sulphate from CaCO<sub>3</sub>.

- (c) Calcium nitrate from calcium sulphate.
- (d) Anhydrous MgCl<sub>2</sub> from hydrated magnesium chloride.
- (e) Plaster of Paris from gypsum.
- 13. Arrange the following:
  - (i) Mg<sup>2+</sup>, Sr<sup>2+</sup>, Be<sup>2+</sup>, Ca<sup>2+</sup> and Ba<sup>2+</sup> ions in the increasing order of their heats of hydration.
  - (ii) CaI<sub>2</sub>, CaF<sub>2</sub>, CaCl<sub>2</sub> and CaBr<sub>2</sub> in order of decreasing melting points.
  - (iii) CaCl<sub>2</sub>, BeCl<sub>2</sub>, MgCl<sub>2</sub>, BaCl<sub>2</sub> and SrCl<sub>2</sub> in order of decreasing ionic character.
  - (iv) MgO, SrO, K<sub>2</sub>O and Cs<sub>2</sub>O in order of increasing basic character. [I.J.T. 1991]
  - (v) CaSO<sub>4</sub>, BaSO<sub>4</sub> and MgSO<sub>4</sub> in order of decreasing solubility in water.
  - (vi) BeCO<sub>3</sub>, MgCO<sub>3</sub>, CaCO<sub>3</sub> and BaCO<sub>3</sub> in order of increasing stability.
  - (vii) Sr, Ba, Ca, Mg in order of increasing reducing nature.
  - (viii) BeSO<sub>4</sub>, MgSO<sub>4</sub>, CaSO<sub>4</sub>, SrSO<sub>4</sub> in order of decreasing [I.I.T. 1997] thermal stability.
- **14.** Answer with giving reason:
  - (i) Which are more electropositive alkali metals or alkaline earth metals?
  - (ii) Which one is a covalent hydride?

BeH2, NaH, CaH2

(iii) Which is more hydrated?

(iv) The solution of which one is acidic?

(v) Which has least hardness?

Na, Be, Li, Ca

(vi) Which has the maximum lattice energy?

(vii) Which one are strong reducing agents?

Alkali metals or alkaline earth metals.

- 15. Describe the preparation, properties and uses of the following compounds:
  - (i) Slaked lime
- (ii) Plaster of Paris
- (iii) Calcium carbide
- (iv) Calcium cyanamide
- (v) Magnesium chloride
- (vi) Magnesium sulphate
- **16.** (a) How can magnesium be extracted from magnesite?
  - (b) How can magnesium be extracted from sea water?
  - (c) How various compounds of barium are obtained from barytes?
  - (d) How portland cement is manufactured?
  - (e) How metal calcium is manufactured?
- 17. Explain the following:
  - (i) Magnesium oxide is used for lining of steel making furnace.

[Hint: MgO is a basic flux and helps in the removal of acidic impurities from steel through slag formation.

$$Si + O_2 \longrightarrow SiO_2;$$
  $MgO + SiO_2 \longrightarrow MgSiO_3$ 

$$4P + 5O_2 \longrightarrow P_4O_{10}; 6MgO + P_4O_{10} \longrightarrow 2Mg_3(PO_4)_2$$
  

$$S + O_2 \longrightarrow SO_2; \qquad MgO + SO_2 \longrightarrow MgSO_3]$$

(ii) Anhydrous calcium sulphate (anhydrite) cannot be used as plaster of Paris.

[Hint: Anhydrous calcium sulphate in presence of water does not set like plaster of Paris. However, it is directly changed to gypsum.]

(iii) Anhydrous magnesium chloride is prepared by heating MgCl<sub>2</sub>·6H<sub>2</sub>O in a current of HCl.

[Hint: Magnesium chloride undergoes hydrolysis with its own water of crystallisation. This hydrolysis is prevented in presence of HCl.]

(iv) The reaction between marble and dilute H<sub>2</sub>SO<sub>4</sub> is not used to prepare carbon dioxide.

[Hint: Insoluble CaSO<sub>4</sub> is formed which deposits on the surface of marble and prevents further action of dilute H<sub>2</sub>SO<sub>4</sub>, so the evolution of CO<sub>2</sub> ceases after some-

(v) Lime water becomes turbid on passing CO<sub>2</sub> through it, but becomes clear when more CO<sub>2</sub> is passed.

[Hint: Insoluble CaCO<sub>3</sub> is first precipitated which dissolves in excess of CO<sub>2</sub> in the form of Ca(HCO<sub>3</sub>)<sub>2</sub>.

$$\begin{array}{ccc} \text{Ca(OH)}_2 + \text{CO}_2 & \longrightarrow & \text{CaCO}_3 + \text{H}_2\text{O}; \\ & & \text{(Insoluble)} \\ \text{CaCO}_3 + \text{H}_2\text{O} + \text{CO}_2 & \longrightarrow & \text{Ca(HCO}_3)_2] \\ & & & \text{(Soluble)} \end{array}$$

(vi) In the manufacture of Mg by carbon reduction of MgO, the product is cooled in the stream of an inert gas.

[Hint: The reduction of MgO is a reversible process. In order to prevent the reaction between Mg and CO, the temperature of the products is reduced in a stream of an inert gas. Inert gas does not permit the reaction of Mg with air.

$$MgO + C \iff Mg + CO$$

(vii) Magnesium metal burns in air to give a white ash. When this ash is treated with water, the odour of ammonia can be detected. What is the reason? [B.I.T. 1990]

**Hint:** The white ash consists small amount of magnesium nitride which is formed along with MgO when Mg burns in air. Magnesium nitride is hydrolysed with water and NH<sub>3</sub> is evolved.]

(viii) The first ionisation potential of alkaline earth metals is low and hence they should prefer to form  $M^+$  ions. In fact they form  $M^{2+}$  ions.

**Hint:**  $M^{2+}$  ions are extensively hydrated to form hydrated ions and a large amount of energy is released. This energy more than counter balances the higher value of second ionisation energy.]

(ix) Alkaline earth metals have higher melting points than alkali metals.

[Hint: Metallic bonding is much stronger in alkaline earth metals as two electrons are present in valence shell.]

(x) Why gypsum is added to cement?

**Hint:** The purpose of adding gypsum is to increase the setting time of the cement.]

(xi) Beryllium sulphate is soluble but BaSO<sub>4</sub> is insoluble.

[Hint: Because of high hydration energy of beryllium ion, its sulphate is soluble. Barium being a larger cation has much lower hydration energy.]

(xii) Beryllium does not exhibit a covalency beyond 4.

[Hint: The outermost energy shell in beryllium is the second. It cannot accommodate more than 8 electrons and hence a covalency limit 4 cannot be exceeded.]

(xiii) The crystalline salts of alkaline earth metals contain more water of crystallisation than the corresponding alkali metal salts. Why? H.I.T. 19971

[Hint: The ionic radii of alkaline earth metal ions are smaller than alkali metal ions.]

18. Element A burns in nitrogen to give an ionic compound B. Compound B reacts with water to give C and D. A solution of C becomes milky on bubbling carbon dioxide. Identify A, B, C and D. [I.I.T. 1997]

[Hint: The element A is calcium.

### Matching Type Questions

#### Match the following:

[A] (a) Anhydrite

(b) Carnallite

(c) Dolomite

(d) Epsomite

(e) Fluorapatite

[B] (a) Gypsum

(b) Hydrolith

(c) Marble

(d) Bone ash

(e) Slaked lime

(f) Quick lime

[C] (a) Nitrolim

(b) Green flame

(c) Brick red flame

(d) Asbestos

(e) Electron

(f) Sorel cement

(i) CaSO<sub>4</sub>

(ii) KCl·MgCl<sub>2</sub>·6H<sub>2</sub>O

(iii) MgSO<sub>4</sub>·7H<sub>2</sub>O

(iv) Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>·CaF<sub>2</sub>

(v) MgCO<sub>3</sub>·CaCO<sub>3</sub>

(i) CaH<sub>2</sub>

(ii) CaO

(iii) Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>

(iv) CaSO<sub>4</sub>·2H<sub>2</sub>O

(v) CaCO<sub>3</sub>

(vi) Ca(OH)2

(i) Calcium salts

(ii) CaMg<sub>3</sub>(SiO<sub>4</sub>)<sub>4</sub>

(iii) MgCl<sub>2</sub>·5MgO·xH<sub>2</sub>O

(iv) 95% Mg, 5% Zn

(v)  $CaCN_2 + C$ 

(vi) Barium salts

### Answers

### Answers: Subjective Type Questions

- 1. (a) Beryllium halides are somewhat covalent in nature.
  - (b) Beryllium chloride undergoes hydrolysis. HCl is given out.

$$BeCl_2 + 2H_2O \longrightarrow Be(OH)_2 + 2HCl$$

(c) CaCO3 is converted into soluble calcium bicarbonate.

$$CaCO_3 + H_2O + CO_2 \longrightarrow Ca(HCO_3)_2$$

(d) Mg reacts with SO2 forming MgO and S.

$$2Mg + SO_2 \longrightarrow 2MgO + S$$

(e) CaCl2 reacts with ammonia.

$$CaCl_2 + 8NH_3 \longrightarrow CaCl_2 \cdot 8NH_3$$
Addition product

- 2. (i) (a) Limestone (b) Chalk (c) Marble
  - (ii) Calcium (iii) Radium (iv) Dolomite
  - (v) Magnesite, Epsom salt (vi) Calcium
- 3. (a) Be; BeO dissolved in NaOH
  - (b) Be (c) Be(OH)<sub>2</sub> (d) Be and Mg (e)  $Ba^{2+}$
  - (f) Anhydrous calcium sulphate (CaSO<sub>4</sub>)
  - (g) It is a waste product from steel industry and has properties similar to cement. It mainly consists calcium silicate.
- 4. (i) Calcium hydride, CaH<sub>2</sub>, (ii) Sorel cement, MgCl<sub>2</sub>·5MgOxH<sub>2</sub>O,
  - (iii) Bleaching powder, CaOCl<sub>2</sub>·H<sub>2</sub>O, (iv) Anhydrone, Mg(ClO<sub>4</sub>)<sub>2</sub>.

[Hint: It has strong affinity for water giving Mg(ClO<sub>4</sub>)<sub>2</sub>·6H<sub>2</sub>O.

It loses whole of water when heated at 250°C and drying property is regenerated.]

- (v) Calcium oxide, CaO.
- 5. (i) increases, (ii) decreases, (iii) decreases, (iv) decreases,
  - (v) increases, (vii increases, (viii) decreases,
  - (ix) increases, (x) increases.
- **6.** (a) CaO, (b)  $Ca(OH)_2$ , (c)  $Mg(ClO_4)_2$ , (d)  $Ba(OH)_2$ , (e)  $CaCO_3$ ,
  - (f)  $CaSO_4$ , (g)  $CaSO_4 \cdot 2H_2O$ , (h)  $2CaSO_4 \cdot H_2O$ , (i)  $CaMg_3(SiO_4)_4$ ,
  - (j) CaH<sub>2</sub>.
- 7. (i) 3BeO·Al<sub>2</sub>O<sub>3</sub>·6SiO<sub>2</sub>, (ii) MgCO<sub>3</sub>, (iii) MgSO<sub>4</sub>·H<sub>2</sub>O, (iv) BaCO<sub>3</sub>,
  - (v) SrSO<sub>4</sub>, (vi) MgSO<sub>4</sub>·7H<sub>2</sub>O<sub>7</sub>, (vii) BeO·Al<sub>2</sub>O<sub>3</sub>, (viii) BaSO<sub>4</sub>,
  - (ix)  $SrCO_3$ , (x)  $CaF_2$ .
- 8. (i)  $MgCl_2 \cdot 6H_2O \xrightarrow{Heat} MgCl_2 \cdot 2H_2O \xrightarrow{Heat} Mg(OH)Cl + HCl + H_2O$

1100

#### MgO

(ii)  $CaSO_4 \cdot 2H_2O \xrightarrow{Heat} CaSO_4 \cdot 2H_2O \xrightarrow{120^{\circ}C} 2CaSO_4 \cdot H_2O$ (Monoclinic) (Orthorhombic) Plaster of Paris

$$CaO + SO_2 + \frac{1}{2}O_2 \xleftarrow{Strongly}_{Heated} \quad CaSO_4 \xleftarrow{Heat}_{Burnt \ plaster}$$

(iii)  $M(HCO_3)_2 \longrightarrow MCO_3 + H_2O + CO_2$ 

- (v)  $Ba(NO_3)_2 \longrightarrow BaO + NO_2 + O_2$
- 9. (i) Methane is evolved. Be<sub>2</sub>C +  $4H_2O \longrightarrow 2Be(OH)_2 + CH_4$ 
  - (ii) Acetylene is evolved.  $CaC_2 + 2H_2O \longrightarrow Ca(OH)_2 + C_2H_2$

- (iii) Ammonia is evolved.  $Ca_3N_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2NH_3$
- (iv) Ammonia is evolved.  $CaCN_2 + 3H_2O \longrightarrow CaCO_3 + 2NH_3$
- (v) Hydrogen is evolved.  $CaH_2 + 2H_2O \longrightarrow Ca(OH)_2 + 2H_2$
- 10. (i) Magnesium forms magnesium oxide and magnesium nitride.

$$2Mg + O_2 \longrightarrow 2MgO$$

$$3Mg + N_2 \longrightarrow Mg_3N_2$$

MgO combines with water very slowly forming magnesium hydroxide. Mg<sub>3</sub>N<sub>2</sub> reacts with water evolving ammonia.

$$MgO + H_2O \longrightarrow Mg(OH)_2$$

$$Mg_3N_2 + 6H_2O \longrightarrow 3Mg(OH)_2 + 2NH_3$$

(ii) Acetylene is evolved. This is passed through dilute H<sub>2</sub>SO<sub>4</sub> when acetaldehyde is formed.

$$\begin{aligned} &\text{CaC}_2 + 2\text{H}_2\text{O} & \longrightarrow \text{Ca(OH)}_2 + \text{C}_2\text{H}_2 \\ &\text{C}_2\text{H}_2 + \text{H}_2\text{O} & \xrightarrow{\text{H}_2\text{SO}_4} & \text{CH}_3\text{CHO} \end{aligned}$$

(iii) Anhydrous ammonium chloride is obtained.

$$MgCl_2 \cdot 6H_2O + NH_4Cl \longrightarrow MgCl_2 \cdot NH_4Cl \cdot 6H_2O$$

 $\mathsf{MgCl}_2 \cdot \mathsf{NH}_4 \mathsf{Cl} \cdot \mathsf{6H}_2 \mathsf{O} \xrightarrow[-6H_2\mathsf{O}]{\mathsf{Heat}} \mathsf{MgCl}_2 \cdot \mathsf{NH}_4 \mathsf{Cl} \xrightarrow[-6H_2\mathsf{O}]{\mathsf{Heat}} \mathsf{MgCl}_2 + \mathsf{NH}_4 \mathsf{Cl}$ 

(iv) 
$$FeCl_3 + 3H_2O \longrightarrow Fe(OH)_3 + 3HCl$$
.

$$Mg \,+\, 2HCl \,\longrightarrow MgCl_2 \,+\, H_2$$

(v) 
$$Mg + 2NH_4Cl \longrightarrow MgCl_2 + 2NH_3 + H_2$$

(vi) The solution becomes milky due to formation of CaCO<sub>3</sub>. The solution again becomes colourless in excess of CO<sub>2</sub> as CaCO<sub>3</sub> dissolves in the form of calcium bicarbonate.

$$Ca(OH)_2 + CO_2 \longrightarrow CaCO_3 + H_2O$$

$$CaCO_3 + H_2O + CO_2 \longrightarrow Ca(HCO_3)_2$$

(vii) 
$$Ca(OH)_2 + SO_2 \longrightarrow CaSO_3 + H_2O$$

$$CaSO_3 + SO_2 + H_2O \longrightarrow Ca(HSO_3)_2$$

(viii) (a) With cold milk of lime, calcium hypochlorite is formed.

$$2Ca(OH)_2 + 2Cl_2 \longrightarrow CaCl_2 + Ca(ClO)_2 + 2H_2O$$

(b) With hot conc. solution of Ca(OH)<sub>2</sub>, calcium chlorate is formed

$$6Ca(OH)_2 + 3Cl_2 \longrightarrow 5CaCl_2 + Ca(ClO_3)_2 + 6H_2O$$

(c) With cold solid Ca(OH)2, bleaching powder is formed.

$$Ca(OH)_2 + Cl_2 \longrightarrow CaOCl_2 + H_2O$$

11. (a) 
$$Mg(HCO_3)_2 + Ca(OH)_2 \longrightarrow MgCO_3 + CaCO_3 + 2H_2O$$

(b) 
$$MgO + CaC_2 \xrightarrow{Heat} Mg + CaO + 2C$$

- (c)  $Be(OH)_2 + 2NaOH \longrightarrow Na_2BeO_2 + 2H_2O$
- (d)  $BaCO_3 + H_2O(steam) \longrightarrow Ba(OH)_2 + CO_2$
- (e)  $2BeCl_2 + LiAlH_4 \longrightarrow 2BeH_2 + LiCl + AlCl_3$

(f) 
$$CaO + 3C \longrightarrow CaC_2 + CO$$

$$CaC_2 + N_2 \longrightarrow CaCN_2 + C$$

- 12. (a)  $CaCO_3 \xrightarrow{Heat} CaO \xrightarrow{H_2O} Ca(OH)_2 \xrightarrow{Cl_2} CaOCl_2$ 
  - (b)  $CaCO_3 \xrightarrow{HCl} CaCl_2 \cdot 6H_2O \xrightarrow{Dil. H_2SO_4} CaSO_4 \cdot 2H_2O$
  - (c)  $CaSO_4 \cdot 2H_2O \xrightarrow{Strongly} CaO \xrightarrow{Dil. HNO_3} Ca(NO_3)_2$

- $(d) \quad MgCl_2 \cdot 6H_2O \xrightarrow{\quad HCl \ or \ NH_4Cl \quad \\ \quad heated \quad }$
- (e)  $CaSO_4 \cdot 2H_2O \xrightarrow{Heated at} 2CaSO_4 \cdot H_2O$
- (i)  $Ba^{2+} < Sr^{2+} < Ca^{2+} < Mg^{2+} < Be^{2+}$ 
  - (ii)  $CaF_2 > CaCl_2 > CaBr_2 > CaI_2$
  - (iii)  $BaCl_2 > SrCl_2 > CaCl_2 > MgCl_2 > BeCl_2$
  - (iv)  $MgO < SrO < K_2O < Cs_2O$
  - (v)  $MgSO_4 > CaSO_4 > BaSO_4$
  - (vi) BeCO<sub>3</sub> < MgCO<sub>3</sub> < CaCO<sub>3</sub> < BaCO<sub>3</sub>
  - (vii) Mg < Ca < Sr < Ba
  - (viii) SrSO<sub>4</sub> > CaSO<sub>4</sub> > MgSO<sub>4</sub> > BeSO<sub>4</sub>
- (i) Alkali metals, low ionisation potential.

- (ii) BeH2, low electronegativity of Be, high ionisation potential.
- (iii) Be<sup>2+</sup>, smallest in size.
- (iv) BeCl<sub>2</sub>, hydrolysis occurs, BeCl<sub>2</sub> +  $2H_2O \rightarrow Be(OH)_2 + 2HCl$
- (v) Na, lowest metallic bonding.
- (vi) MgO, Mg<sup>2+</sup> ion is smallest in size and double the charge in comparison to Li<sup>+</sup> and Na<sup>+</sup> ions.
- (vii) Alkali metals, the values of oxidation potentials are high.

### **Answers:** Matching Type Questions

- [A] (a-i); (b-ii); (c-v); (d-iii); (e-iv)
- [B] (a-iv); (b-i); (c-v); (d-iii); (e-vi); (f-ii)
- [C] (a-v); (b-vi); (c-i); (d-ii); (e-iv); (f-iii)

### ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. Amongst the following hydroxides, the one which has lowest value of  $K_{\rm sp}$  at ordinary temperature is?
  - (a)  $Be(OH)_2$
- (b)  $Mg(OH)_2$
- (c) Ca(OH)<sub>2</sub>
- (d) Ba(OH)<sub>2</sub>

Ans. (a)

[Hint: Be(OH)<sub>2</sub> is least soluble in water.]

- Yellow phosphorus on reaction with Ca(OH)<sub>2</sub> gives:
  - (a)  $Ca(H_2PO_4)_2$
- (b)  $Ca(H_2PO_2)_2$
- (c) PH<sub>3</sub>
- (d) both (b) and (c)

Ans. (d)

[Hint:  $8P + 3Ca(OH)_2 + 6H_2O \longrightarrow 3Ca(H_2PO_2)_2 + 2PH_3$ ]

- 3. Slaked lime is obtained when water is added to:
  - (a) CaSO<sub>4</sub>· $\frac{1}{2}$ H<sub>2</sub>O
- (b) CaCl<sub>2</sub>

(c) CaO

(d) CaCO<sub>3</sub>

Ans. (c)

[Hint: The slaked lime is calcium hydroxide. It is obtained when water is added to CaO (Lime).

$$CaO + H_2O \longrightarrow Ca(OH)_2$$
]

- As compared to alkali metals, alkaline earth metals:
  - (a) are more metallic
  - (b) have higher densities
  - (c) are stronger reducing agents
  - (d) have larger atomic radii
  - Ans. (b)
- 5. Which of the following carbides give allylene on hydrolysis?
  - (a) CaC<sub>2</sub>

- (b) Be<sub>2</sub>C
- (c) MgC<sub>2</sub>
- (d)  $Mg_2C_3$

Ans. (d)

[Hint:  $Mg_2C_3 + 4H_2O \longrightarrow 2Mg(OH)_2 + CH_3 \longrightarrow C \cong CH$ ]

- 6. Black ash is:
  - (a) CaS + NaHCO<sub>3</sub>
- (b)  $CaSO_4 + Na_2CO_3$
- (c)  $CaSO_4 + NaHCO_3$

- (d)  $CaS + Na_2CO_3$

Ans. (d)

- 7. Metallic magnesium is obtained by:
  - (a) reduction of MgO with coke
  - (b) electrolysis of an aqueous solution of MgCl<sub>2</sub>
  - (c) electrolysis of molten MgCl<sub>2</sub>
  - (d) displacement of magnesium by iron from MgCl<sub>2</sub> solution Ans. (c)
- 8. Among the alkaline earth metals, the element forming predominantly covalent compounds is:
  - (a) barium
- (b) beryllium
- (c) strontium
- (d) calcium

Ans. (b)

[Hint: Be<sup>2+</sup> ion has a small size. It has high polarising power.]

- 9. Magnesium is an important component of which biomolecule occurring extensively in living world?
  - (a) Haemoglobin
- (b) ATP
- (c) Chlorophyll
- (d) Vitamin  $B_{12}$

- Ans. (c)
- 10. The solubilities of carbonates decrease down the magnesium group due to a decrease in:
  - (a) entropy of solution formation
  - (b) lattice energies of solids
  - (c) hydration energies of cations
  - (d) inter-ionic attraction

Ans. (c)

- 11. Several blocks of magnesium are fixed to the bottom of a ship
  - (a) prevent action of water and salt
  - (b) prevent puncturing by under sea rocks
  - (c) keep away the sharks
  - (d) make the ship lighter
- 12. A metal M readily forms water soluble sulphate MSO<sub>4</sub>, water insoluble hydroxide  $M(OH)_2$  and oxide MO which becomes inert on heating. The hydroxide is soluble in NaOH. Then M is:

(a) Be

(b) Mg

(c) Ca

(d) Sr

Ans. (a)

[Hint: BeSO<sub>4</sub> - soluble; Be(OH)<sub>2</sub> - insoluble

 $Be(OH)_2 + 2NaOH \longrightarrow Na_2BeO_2 + 2H_2O$ 

13. Dead burnt plaster is:

[P.M.T. (Kerala) 2006]

(a) CaSO<sub>4</sub>·2H<sub>2</sub>O

(b) MgSO<sub>4</sub>·7H<sub>2</sub>O

(c)  $CaSO_4 \cdot \frac{1}{2} H_2O$ 

(d) CaSO<sub>4</sub>

Ans. (d)

- **14.** Which of the following statement(s) is/are not true about the diagonal relationship of Be and Al?
  - A. Both react with NaOH to liberate hydrogen
  - B. Their oxides are basic
  - C. They become passive by concentrated HNO<sub>3</sub>
  - D. Their carbides give acetylene on treatment with water
  - (a) Only A

(b) B and C

(c) A and D

(d) B and D

Ans. (d)

[Hint: Their oxides are amphoteric and their carbides give methane on treatment with water.]

- **15.** The correct sequence of increasing covalent character is represented by:
  - (a) BeCl<sub>2</sub> < NaCl < LiCl
- (b) NaCl < LiCl < BeCl<sub>2</sub>
- (c) BeCl<sub>2</sub><LiCl<NaCl
- (d) LiCl < NaCl < BeCl<sub>2</sub>

Ans. (b)

[Hint: The polarizing power of cation increases with decrease in size of cation and increase of charge on the cation.]

16. A solid compound 'X' on heating gives  $CO_2$  gas and a residue. The residue mixed with water forms 'Y'. On passing

an excess of  $CO_2$  through 'Y' in water a clear solution 'Z' is obtained. On boiling 'Z' compound 'X' is reformed. The compound 'X' is:

- (a) Ca(HCO<sub>3</sub>)<sub>2</sub>
- (b) CaCO<sub>3</sub>
- (c) Na<sub>2</sub>CO<sub>3</sub>
- (d) K<sub>2</sub>CO<sub>3</sub>

Ans. (b)

[Hint:

$$\begin{array}{ccc} \text{CaCO}_3 & \longrightarrow & \text{CaO} + \text{CO}_2; \\ `X` & \text{residue} \end{array}$$

$$\text{CaO} + \text{H}_2\text{O} \longrightarrow & \text{Ca(OH)}_2 \end{array}$$

$$Ca(OH)_2 + 2CO_2 \longrightarrow Ca(HCO_3)_2;$$

$$Ca(HCO_3)_2 \xrightarrow{boiling} CaCO_3 + H_2O + CO_2$$
]

- 17. In which of the following, the hydration energy is higher than the lattice energy? [C.B.S.E. 2007]
  - (a) MgSO<sub>4</sub>
- (b) RaSO<sub>4</sub>
- (c) SrSO<sub>4</sub>
- (d) BaSO<sub>4</sub>

Ans. (a)

[Hint: Mg<sup>2+</sup> ion is the smallest and hence has highest hydrationenergy.]

- 18. Be and Al exhibit many properties which are similar. But the two elements differ in: [A.I.E.E.E. 2007]
  - (a) forming covalent bonds
  - (b) forming polymeric hydrides
  - (c) exhibiting maximum covalency in compounds
  - (d) exhibiting amphoteric nature in their oxides Ans. (c)

	(a) ionic nature of BeF <sub>2</sub>		64.	Which of the following it	is least soluble in water?	
	(b) greater hydration energy of Be <sup>2+</sup> ion as compared	l to		(a) BaF <sub>2</sub>	$\Box$ (b) SrF <sub>2</sub>	
	crystal lattice			(c) CaF <sub>2</sub>	$\Box$ (d) MgF <sub>2</sub>	
	(c) covalent nature of BeF <sub>2</sub>		65.	When CaC <sub>2</sub> is heated in	atmospheric nitrogen in ar	n electric
	(d) none of the above			furnace, the compound f		
52.	The order of increasing lattice energy of the follow	ving		(a) Ca(CN) <sub>2</sub>	☐ (b) CaNCN	
	compounds is:			(c) Ca <sub>3</sub> N <sub>2</sub>	☐ (d) CaNC <sub>2</sub>	
	(a) NaCl < CaO < NaBr < BaO		66.	· • • -	owing has the tendency	to form
	(b) NaBr < NaCl < BaO < CaO			covalent compounds?	,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,	101111
	(c) NaCl < NaBr < BaO < CaO			(a) Calcium	☐ (b) Beryllium	
	(d) NaBr < NaCl < CaO < BaO			(c) Strontium	☐ (d) Magnesium	
53.	$Be(OH)_2$ is:		67.		Mg <sup>2+</sup> ions is higher than	
	(a) acidic		07.	(a) Al <sup>3+</sup>	☐ (b) Be <sup>2+</sup>	
	(c) amphoteric			(c) Na <sup>+</sup>		
54.	Hydrolith is the common name of:		60		(d) none of these	
	(a) NaH		08.		metals dissolves in KOH	with the
	(c) CaO			evolution of hydrogen?		
55.	The salts of which of the following give green colour in	fire	l	(a) Ca	□ (b) Mg	
501	works?		60	(c) Sr	☐ (d) Be	
	(a) Na		09.		is used for taking the X-ra	y spectra

	(c) Ca		102. Identify the correct statement:	
90	Ordinary blackboard chalk is made of:			
<i>7</i> 0.	(a) limestone		1 · · · · · =	
	(c) fluorspar		(c) Beryllium hydride and magnesium hydride are covaled	
Q1	The most electropositive amongst the alkaline earth m			
71.	THE HIGH EXCLIPTIONALIVE ATHOUGH THE ATRAITUC CALCULUT	ciais		
			(d) All of these.	
	is;	П		
			103. The compound which is insoluble in dil. HCl is:	

- 11. A sodium salt on treatment with MgCl<sub>2</sub> gives white precipitate on heating. The anion of the sodium salt is:
  - (a) HCO<sub>3</sub>
- (b)  $CO_3^{2^{-}}$

(c)  $SO_4^{2-}$ 

- (d) NO<sub>3</sub>
- $\xrightarrow{\text{Heat}}$  MgCO<sub>3</sub> ] [Hint:  $MgCl_2 + 2NaHCO_3 \longrightarrow Mg(HCO_3)_2$
- 12. Lattice energies of BeF<sub>2</sub>, MgF<sub>2</sub>, CaF<sub>2</sub> and BaF<sub>2</sub> are -2906, -2610, -2459 and -2367 kJ mol<sup>-1</sup> respectively. Hydration energies of Be<sup>2+</sup>, Mg<sup>2+</sup>, Ca<sup>2+</sup>, Ba<sup>2+</sup> and F are -2494, -1921, -1577, -1305 and -457 kJ mol<sup>-1</sup> respectively. Which of the fluorides is soluble in water?
  - (a) BeF<sub>2</sub>

(b) MgF<sub>2</sub>

(c) CaF<sub>2</sub>

(d) BaF<sub>2</sub>

Г	Ti	nt:

	BeF <sub>2</sub>	MgF <sub>2</sub>	CaF <sub>2</sub>	BaF <sub>2</sub>
Hydration	-2494 + 2× (-457)	-1921 + 2 × (-457)	-1577+2×(-457)	-1305 + 2 × (-457)
energy	= - 3408	= - 2835	= ~ 2491	= - 2219
Latticë energy	2906	- 2610	- 2459	- 2367
ΔH solution	- 3408 - (- 2906) = - 502 kJ mol <sup>-1</sup>	-2835 - (-2610) = $-225 \text{ kJ mol}^{-1}$	-2491 - (-2459) = $-32 \text{ kJ mol}^{-1}$	- 2219 - (- 2367) = 148 kJ mol <sup>-1</sup>

 $\Delta H$  solution is -ve in BeF<sub>2</sub>, hence BeF<sub>2</sub> is easily soluble in water.

- 13. The name and the formula of a compound of Ca, C and N used as a fertilizer is:
  - (a) calcium cyanide, Ca (CN)<sub>2</sub>
  - (b) calcium cyanamide, CaCN<sub>2</sub>
  - (c) calcium cyanide having carbon particles,  $(Ca(CN)_2 + C)$
  - (d) calcium cyanamide plus carbon (nitrolim), ( $CaCN_2 + C$ )
- 14. The name and formula of the compound of magnesium, chlorine and oxygen used as a drying agent is:
  - (a) magnesium oxychlorite, Mg(OCl)<sub>2</sub>
  - (b) magnesium chlorate, Mg(ClO<sub>3</sub>)<sub>2</sub>
  - (c) magnesium perchlorate, Mg(ClO<sub>4</sub>)<sub>2</sub>
  - (d) none of the above

[Hint: Magnesium perchlorate (anhydrone) has strong affinity for water giving Mg(ClO<sub>4</sub>)<sub>2</sub>·6H<sub>2</sub>O. It loses whole of water when heated at 250°C and drying property is regenerated.]

15. Match (X) with (Y) and select the correct alternative.

- 1. CaH<sub>2</sub>
- A. Sorel cement B. Anhydrone
- 2.  $BaSO_4 + ZnS$

Y

- C. Hydrolith
- 3. MgCl<sub>2</sub>·5MgO·xH<sub>2</sub>O

### Matrix Matching Questions for IIT Aspirants

Match List-I with List-II:

### List-I

#### List-II

- (a) Sorel's cement
- (p) MgCl<sub>2</sub>
- (b) Albite
- (q) MgO
- (c) A salt of carnallite
- (r) NaAlSi<sub>3</sub>O<sub>8</sub>
- (d) Glauber's salt
- (s) Na<sub>2</sub>SO<sub>4</sub>·10H<sub>2</sub>O
- Match the metals in List-I with their ore in List-II and formula in List-III:

List-I
--------

### List-II

### List-III

(Metal)

(Name of ore)

(Composition of ore)

- (a) Lithium (b) Sodium
- (p) Kiesserite (q) Spodumene
- (u) LiAlSi2O6 (v) NaNO<sub>3</sub>

- (c) Calcium
- (w) MgSO<sub>4</sub>·H<sub>2</sub>O

- (r) Fluorspar

- (d) Magnesium
- (s) Chile saltpetre
- (x) CaF<sub>2</sub>

(e-s)

- 3. Match the common name of the compounds in List-I with its chemical formula in List-II:

#### List-I

(a) Brine

- (b) Rock salt
- (q) NaCl
- (c) Sylvine
- (r)  $MgSO_4 \cdot 7H_2O$
- (d) Epsomite
- (e) Fly ash

- List-II
- (p) KCl
- (s) CaSiO<sub>3</sub>

Match the elements in List-I with their nature in List-II:

### List-I

- (a) Be
- (b) Fr
- (c) Ra
- (d) Mg
- Match List-I with List-II:

#### List-I

#### (Compounds)

- (a) Magnesium oxide
- (b) Barium sulphate
- (c) Calcium cyanamide
- (d) Magnesium sulphate

- List-II
- (p) Radioactive
- (q) Form covalent hydride
- (r) Form amphoteric oxide
- (s) Do not impart any colour
- to Bunsen flame

#### List-II

### (Use of compounds)

- (p) Fertilizer
- (q) Purgative
- (r) As a constituent of sorel cement
- (s) As a constituent of lithopone
- (t) Refractory material

(a-p, q)

3.

(a-q-u)

(a-q)

(b-s-v)

(b-q)

- (c-p) (c-r-x)(c-p)
- (d-s)(d-p-w)(d-r)

- (d-s)(d-q)
- (a-r, t) (b-s)(c-p)

### Assertion-Reason Type Questions

In each of the following questions, two statements are given as Assertion (A) and Reason (R). Examine the statements and answer the questions according to the instructions given below. Mark:

- (a) if both (A) and (R) are correct and (R) is the correct explanation of (A).
- (b) if both (A) and (R) are correct and (R) is not the correct explanation of (A).
- (c) if (A) is correct and (R) is wrong.
- (d) if (A) is wrong and (R) is correct.
- (e) if both (A) and (R) are wrong.
- 1. (A) Beryllium and magnesium do not impart characteristic colour to the Bunsen-burner flame.
  - (R) Both Beryllium and magnesium have high ionisation energy.
- 2. (A) Be(OH)<sub>2</sub> dissolves in excess of NaOH.
  - (R) Be(OH)<sub>2</sub> is an amphoteric compound.
- 3. (A) Alkaline earth metals are softer than alkali metals.
  - (R) Atomic radii of alkaline earth metals are smaller than corresponding alkali metals in the same periods of periodic table.

- 4. (A) Beryllium compounds are covalent in nature.
  - (R) The size of Be<sup>2+</sup> ion is larger in comparison to the radii of the other divalent ions of alkaline earth metals.
- 5. (A) Lithium resembles magnesium.
  - (R) Li<sup>+</sup> has same size as Mg<sup>2+</sup>.
- [A.I.I.M.S. 1997]
- 6. (A) The fluorides of alkaline earth metals are almost insoluble in water.
  - (R) The lattice energies of the fluorides of alkaline earth metals are very high.
- 7. (A) Sulphur is estimated as BaSO<sub>4</sub> and not as MgSO<sub>4</sub>.
   (R) The ionic radius of Mg<sup>2+</sup> is smaller than that of Ba<sup>2+</sup>
- 8. (A) Na<sub>2</sub>SO<sub>4</sub> is soluble in water but BaSO<sub>4</sub> is insoluble.
  - (R) Lattice energy of barium sulphate exceeds its hydration [A.I.I.M.S. 1997]
- 9. (A) MgO is used for lining of steel making furnace.
  - (R) MgO is an acidic flux.
- 10. (A) Magnesium gets oxidised when heated in CO<sub>2</sub> or SO<sub>2</sub>
  - (R) Magnesium has a strong affinity for oxygen.

### HOUGH

### THOUGHT 1

Both alkaline earth metals and alkali metals are s-block elements. They resemble with each other in many respects but still there are certain dissimilarities in their properties on account of different number of electrons in the valency shell, smaller atomic radii, higher ionisation potential, higher electronegativity, etc.

Like lithium, beryllium also differs from rest of the alkaline earth metals on account of its small atomic size and high electronegativity. Be<sup>2+</sup> ion is very small and exerts a high polarising effect on any anion associated with it.

- 1. The correct sequence of increasing covalent character is represented by:

  - (a)  $BeCl_2 < NaCl < LiCl$  (b)  $NaCl < LiCl < BeCl_2$

  - (c) BeCl<sub>2</sub> < LiCl < NaCl (d) LiCl < NaCl < BeCl<sub>2</sub>
- 2. Which is least thermally stable?
  - (a) Li<sub>2</sub>CO<sub>3</sub>
- (b) MgCO<sub>3</sub>
- (c) BaCO<sub>3</sub>
- (d) BeCO<sub>3</sub>
- 3. Which of the following statements are true for II A group elements?
  - (a) Lattice energy of oxides, carbonates, fluorides decreases from Be to Ba.
  - (b) All form nitrides in air.
  - (c) The solubility of the hydroxides increases from Be to Ba.
  - (d) All are correct.
- The alkaline earth metal which does not directly combine with hydrogen is:
  - (a) Be

(b) Ca

(c) Sr

- (d) Ba
- 5. The solubility in water of sulphates down the IIA group is: Be > Mg > Ca > Sr > Ba

This is due to:

- (a) increase in melting point
- (b) increasing molecular mass
- (c) decreasing lattice energy
- (d) high heat of solvation for smaller ions
- 6. Which of the bicarbonate does not exist in solid state?
  - (a) NaHCO<sub>3</sub>
- (b) KHCO<sub>3</sub>
- (c) Ca(HCO<sub>3</sub>)<sub>2</sub>
- (d) RbHCO<sub>3</sub>

entes i som vinnige tekning a entrangenenmententen med staten med tekningen med ver en i vin i vin i vin viv v

- 7. The element which does not directly combine with carbon on strong heating:
  - (a) Li

(b) Be

(c) K

(d) Ca

### **THOUGHT 2**

Cement is one of the most important building material of the present time. It is a dirty greyish heavy powder containing cal-

cium aluminates and silicates. The important raw materials needed for the manufacture of cement are, limestone, clay and gypsum. The main step in the manufacture of cement is the heating of raw meal or slurry in the rotary kiln at a very high temperature 1400-1600°C. Finally 2 or 3% gypsum is added.

When cement is mixed with water and left as such for some time, it becomes a hard mass. This is known as setting of cement. It is believed that various aluminates and silicates present in the cement form hydrates with water which separate in the form of gel. The gels formed start losing water partly by evaporation and partly by forming hydrates with unhydrated constituents. This results in the formation of a hard mass.

- 1. Portland cement does not contain:
  - (a) CaSiO<sub>4</sub>
- (b) CaSiO<sub>3</sub>
- (c) Ca<sub>3</sub>·Al<sub>2</sub>O<sub>6</sub>
- (d) Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>
- 2. Setting of cement is:
  - (a) exothermic reaction
- (b) endothermic reaction
- (c) hydration process
- (d) none of these
- 3. The percentage of lime in portland cement is approximately:
  - (a) 20 25%
- (b) 30 40%
- (c) 60-65%
- (d) 40 50%
- 4. Concrete is a mixture of:
  - (a) cement, sand, gravel and water
  - (b) cement, limestone and water
  - (c) cement, slaked lime and water
  - (d) cement, sand and water
- 5. Gypsum is added to portland cement:
  - (a) to fasten the process of setting
  - (b) to slow down the process of setting
  - (c) to improve the colour of the cement
  - (d) all of the above are incorrect

### THOUGHT 3

Metal nitrate (A) on heating decomposes, leaving a solid residue (B) which goes into solution with dilute HCl. The solution of (B)gives a white precipitate with ammonium carbonate solution. The precipitate (C) is dissolved in dilute HCl and the solution is treated with potassium chromate to get yellow precipitate (D). The solution (B) with dilute H<sub>2</sub>SO<sub>4</sub> also gives a white precipitate (E) insoluble in dilute HCl and nitric acid. The precipitate (E) is a part of a white pigment lithopone.

- 1. The compound (E) is:
  - (a) BaSO<sub>4</sub>
- (b) MgSO<sub>4</sub>

and was to have an expensive term who were the construction of the construction of the construction of the construction and the construction of th

- (c) CaSO<sub>4</sub>
- (d) Na<sub>2</sub>SO<sub>4</sub>
- 2. The yellow precipitate (D) is:
  - (a) PbCrO<sub>4</sub>
- (b) BaCrO<sub>4</sub>
- (c) CaCrO<sub>4</sub>
- (d) none of these

3. The metal nitrate (A) is:

(a) Ca(NO<sub>3</sub>)<sub>2</sub>

(b)  $Pb(NO_3)_2$ 

(c) Ba(NO<sub>3</sub>)<sub>2</sub>

(d) KNO<sub>3</sub>

**4.** The solid residue (B) is:

(a) CaO

(b) PbO

(c) ZnO (d) BaO

5. The nitrate (A) can be confirmed by flame test. The colour

imparted by the salt to the flame is:

(a) yellow

(b) green

(c) blue

(d) red

### **THOUGHT 4**

Limestone is a naturally occuring form of calcium carbonate. It is used as building material and also for manufacture of other building materials such as Portland cement. It is used for the production of quick lime and slaked lime which have wide applications in chemical, metallurgical and construction industry. The pure CaCO3, ealled precipitated calcium carbonate, is used extensively as filler providing bulk to materials such as paint, plastics, printing inks and rubber. It is also used in toothpastes, cosmetics and antacids. Quick lime and slaked lime are the cheapest and most widely used bases for neutralising unwanted acids. Lime is used to neutralise acidic soils. An important application of quick lime is in air pollution control for the removal of SO2 in electric power plants. Slaked lime is used in the

manufacture of other alkalies and bleaching powder, in sugar refining, in tanning hides and in water softening.

1. The substance not likely to contain CaCO3 is:

(a) dolomite

(b) a marble statue

(c) sea shells

(d) calcined gypsum

2. Slaked lime reacts with chlorine to give:

(a) CaCl<sub>2</sub>

(b) CaO

(c) CaOCl<sub>2</sub>

(d) CaCO<sub>3</sub>

3. Quick lime is:

(a) CaO

(b) CaCO<sub>3</sub>

(c) Ca(OH)<sub>2</sub>

(d) CaSO<sub>4</sub>

4. The drying agent which absorbs CO<sub>2</sub> and reacts violently with water is:

(a) sodium carbonate

(b) quick lime

(c) conc. H<sub>2</sub>SO<sub>4</sub>

(d) alcohol

5. Chemical compound 'A' is used to remove temporary hardness from water. It reacts with Na<sub>2</sub>CO<sub>3</sub> to generate caustic soda. When CO<sub>2</sub> is passed through 'A' it turns cloudy. What is 'A'?

(a) CaCO<sub>3</sub>

(b) Ca(HCO<sub>3</sub>)<sub>2</sub>

(c) Ca(OH)<sub>2</sub>

(d) CaCl<sub>2</sub>

**6.** Quick lime is used in electric power plants with carbon to check pollution. What product of calcium is formed?

(a) CaSO<sub>3</sub>

(b) CaSO<sub>4</sub>

(c) CaS

(d) CaSO<sub>4</sub>·10H<sub>2</sub>O

### INTEGER ANSWER Type Questions

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

- 1. How many alkaline earth metals are known?
- 2. How many water molecules are associated with 'Epsom salt'?
- 3. Magnesium oxide when mixed with a saturated solution of magnesium chloride sets to a hard mass like cement known as 'sorel cement'. The composition of sorel cement is MgCl<sub>2</sub>nMgOxH<sub>2</sub>O. What is the value of n?
- 4. On heating calcium ammoniate, ammonia and hydrogen are evolved. How many moles of ammonia are evolved when 1.5 moles of calcium ammoniate are heated?
- 5. Magnalium is an alloy of aluminium and magnesium. What is the percentage of magnesium in this alloy?
- 6. Calcium carbide reacts with nitrogen and forms an important fertilizer, calcium cyanamide. How much calcium cyanamide is formed when 3.2 g of calcium carbide is completely converted into cyanamide?

### Answers

- 1. (6) Be, Mg, Ca, Sr, Ba and Ra are alkaline earth metals.
- 2. (7) Epsom salt has the molecular formula, MgSO<sub>4</sub>·7H<sub>2</sub>O.
- 3. (5)  $MgCl_2 \cdot 5MgOxH_2O$
- 4. (8)  $3\text{Ca}(\text{NH}_3)_6 \longrightarrow \text{Ca}_3\text{N}_2 + 16\text{NH}_3 + 3\text{H}_2$  $\begin{array}{c} 3 \text{ moles} \\ 1.5 \text{ moles} \\ \end{array}$  8 moles

- 5. (5) Magnalium: 95% Al + 5% Mg
- 6. (4)  $CaC_2 + N_2 \longrightarrow CaCN_2 + C$ 64 g
  80 g

$$=\frac{80}{64}\times3.2=4$$

## Revision Exercise (Chapter 5 to 7)

NIC	GLE CORRECT ANSWER TYPE			(d) all of these	Ш
1.	The pair that yields the same gaseous product on reacti	on	10.	The deep colour produced when iodine is dissolved in solution of KI is caused by the presence of:	a a
	with water:			(a) $I_3$ $\Box$ (b) $I^-$	
	(a) K and $KO_2$ $\square$ (b) Ca and $CaH_2$			$\begin{array}{ccc} \text{(a)} & I_3 & & \square & \text{(b)} & I \\ \text{(c)} & I_{\overline{2}} & & \square & \text{(d)} & I_2 \end{array}$	
	(c) Na and Na <sub>2</sub> O <sub>2</sub> $\Box$ (d) Ba and BaO <sub>2</sub>		11	Dissolving NaNH <sub>2</sub> in water will give:	<b></b>
2.	Acidified K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> on oxidation by H <sub>2</sub> O <sub>2</sub> gives :		11.	(a) a solution containing solvated Na <sup>+</sup> ions, OH <sup>-</sup> ions a	and
	(a) Blue solution $\Box$ (b) $CrO_5$			NH <sub>3</sub>	anu —
	(c) Chromium peroxide $\Box$ (d) all of these			(b) a solution containing solvated Na <sup>+</sup> and NH <sub>2</sub> ions	
3.	Select the reaction which does not occur.			(c) NH <sub>3</sub> and metallic sodium	
	(a) $NaNH_2 + C \xrightarrow{750^{\circ}C} NaH + HCN$			(d) solvated Na <sup>+</sup> ions and hydrogen gas	
- 15 5000	(b) $6\text{NaOH} + 4\text{S} \xrightarrow{\text{Heat}} \text{Na}_2\text{S}_2\text{O}_3 + 2\text{Na}_2\text{S} + 3\text{H}_2\text{O}$		12.	Temporary and permanent hardness can be removed	by
	(c) $Na(NH_4)HPO_4 \xrightarrow{Heat} NaPO_3 + NH_3 + H_2O$			addition of and respectively.	
				(a) $CaO, CaCO_3$ $\Box$ (b) $CaO, Na_2CO_3$	
4	(d) $2KO_2 + 2H_2O \longrightarrow 2KOH + H_2O_2 + O_2$			(c) $Na_2CO_3$ , $CaO$ $\Box$ (d) $NaHCO_3$ , $CaCl_2$	
4.	The order of increasing thermal stabilities of		13.	$CO_2$ gas along with solid $(Y)$ is obtained when sodium s	
	$K_2CO_3$ , $MgCO_3$ , $CaCO_3$ , $BaCO_3$ is:			$(X)$ is heated. $(X)$ is again obtained when $CO_2$ gas is pass	sed
	$(I) \qquad (II) \qquad (IV)$			into aqueous solution $(Y)$ . $(X)$ and $(Y)$ are:	
	(a) $IV < II < III$			(a) $Na_2CO_3$ , $Na_2O$ $\square$ (b) $Na_2CO_3$ , $NaOH$	
	(c) $II < III < IV < I$ $\Box$ (d) $II < IV < III < I$			(c) $NaHCO_3$ , $Na_2CO_3$ $\square$ (d) $Na_2CO_3$ , $NaHCO_3$	
5.	Alkali metals form hydrated compounds. The hydrati	ion	14.	A metal $M$ readily forms water soluble $MSO_4$ . It also for	
	enthalpies of alkali metals are in the sequence of:			oxide MO which becomes inert on heating. Hydroxide M(Ol	-
	(a) $Rb^+ > Li^+ > Na^+ > K^+ > CS^+$			is insoluble in water but soluble in NaOH solution. Wha	ıt is
	(b) $CS^+ > Rb^+ > K^+ > Na^+ > Li^+$			M?	
	(c) $Li^+ > Na^+ > K^+ > Rb^+ > CS^+$			(a) Mg	
	(d) $K^+ > Na^+ > Li^+ > Rb^+ > CS^+$			(c) Ca	
6	The strength of 10 volume solution of hydrogen peroxide		15.	The correct order of equivalent conductivity at infin	nite
o.	(a) $22.79 \text{ g/L}$ $\Box$ (b) $30.36 \text{ g/L}$	□ □		dilution of LiCl, NaCl and KCl is:	
	(c) $18.5 \text{ g/L}$			(a) LiCl>NaCl>KCl	
7	Ozone reacts with $H_2O_2$ to give oxygen. One volume of ozone			(c) NaCl>KCl>LiCl	
- ' -	gives:	,,,,,	16.	Strong reductant in IIA and IA group is:	
	(a) one volume of oxygen			(a) Ba, Li	
	(b) half volume of oxygen		1	(c) Ba, Cs	
	(c) 1.5 volume of oxygen		17.	The compound (A) on heating gives a colourless gas.	
	(d) two volumes of oxygen			residue is dissolved in water to obtain (B). Excess of CO	
8	Which of the following is incorrect?	lal		bubbled through aqueous solution of $(B)$ , $(C)$ is formed.	
0.	(a) Hydrogen > Deuterium > Tritium (% relative abundan	ce)		on gentle heating gives back (A). The compound (A) is	
	(a) Hydrogon's Souterrain's Hillann' (N 101an', C abdillann			(a) $CaCO_3$ $\Box$ (b) $Na_2CO_3$	
	(b) Hydrogen > Deuterium > Tritium (melting point)		10	(c) $K_2CO_3$ $\Box$ (d) $CaSO_4 \cdot 2H_2O$	
	(c) Hydrogen < Deuterium < Tritium (boiling point)		18.	An alkaline earth metal (M) gives an insoluble sulphate.	
	(d) Hydrogen < Deuterium < Tritium (dissociation energ			mixture of the sulphate and a sulphide of 3d-block m	
	(a) Try drogon ( Dediction ( Triddin (dissociation energy			forms a white pigment which is known as <b>lithophone</b> . M	etai
9.	Highly pure dilute solution of sodium in liquid ammonia			(M) is:	
	(a) shows blue colour			(a) Ca □ (b) Mg (c) Ba □ (d) Sr	
	(b) exhibits electrical conductivity		10		
	(c) acts as a reducing agent		19.	The electrical conductivity of sodium dissolved in liquid N	NII3
	· / · · · · · · · · · · · · · · · · · ·			is due to:	

	(a) ammoniated Na ions Li (b) ammoniated electrons i	U <u>(</u>	<u> IVIC</u>	E OR MORE THAN ONE CORRECT	
	(c) both (a) and (b) $\square$ (d) none of these		ANS	SWERS TYPE	
20.	Which of the following compounds is known as pearl ask	1?	21	Identify the compat statements	
	(a) $KMnO_4$		31.	Identify the correct statements:	
				(a) Mass of H-atom is $1.66 \times 10^{-27}$ kg.	
	Slaked lime is obtained when water is added to:			(b) Cu dissolves in H <sub>2</sub> SO <sub>4</sub> and liberates H <sub>2</sub> .	
	1			(c) H <sub>2</sub> is liberated by the action of Al with conc. NaOH	
		_		(d) Hydrogen contains at room temperature 25% para	and
	Which of the following is generally used for clearing sno			75% ortho form.	
<i>LL</i> .		W	32.	Identify the incorrect statements:	
	from roads during winters in cold countries?  (a) CaF <sub>2</sub>	_		(a) The reactivity of hydrogen towards halogens is in	the
				order $Cl_2 > Br_2 > I_2 > F_2$ .	
22				(b) The oxides of hydrogen and deuterium are neutral.	
25.	The hydride gap refers to inability of:			(c) Molecular hydrogen reduces ZnO and CuO to Zn	and
	(m) 110 110 Busin 10 10 110 110 110 110 110 110 110 110			Cu respectively.	
	(b) elements of group 7, 8 and 9 of the <i>d</i> -block to for			(d) Atomic hydrogen reduces KMnO <sub>4</sub> to meta	allic
				manganese.	
			33.	When chlorine is passed through NaOH solution un	nder
	(d) s-electrons of valency shell of p-block elements to par	ti- 		different dilutions, the main products formed are:	
•	cipate in bonding	⊔		(a) NaCl, NaClO $\Box$ (b) NaCl, NaClO <sub>2</sub>	
24.	Hydride of certain non-metallic element 'X' is amphoteric			(c) NaCl, NaClO <sub>3</sub> $\square$ (d) NaCl, NaClO <sub>4</sub>	
	nature. The hydride of 'X' also reacts with calcium hydrid		34.	Which of the following metals do react with nitrogen w	hen
	(hydrolith) to liberate dihydrogen gas. The element 'X' is	_		heated in its atmosphere?	
				(a) Ca	
	- (-)			(c) Li	
25.	In which of the following reactions water does not act	as	35.	Which of the following nitrates give NO <sub>2</sub> on heating?	
	hydrolytic agent?			(a) $NaNO_3$	
				(c) $KNO_3$	
	() -3-22		36.	Which of the following statements about alkaline earth me	etals
26.	Which elements out of the following do not produ	ce		are correct?	
	hydrogen on treatment with caustic soda?			(a) Hydration energy of Sr <sup>2+</sup> is greater than that of Be <sup>2</sup>	!+.□
	(1) Zn (2) Sn (3) Mg (4) Cu (5) Al	_		(b) CaCO <sub>3</sub> decomposes at a higher temperature than BaC	$CO_3$ .
	(a) (1) and (5)				
	(c) (4) and (5)			(c) Ba(OH) <sub>2</sub> is stronger base than Mg(OH) <sub>2</sub> .	
27.	Which of the following hydrides does conduct electricity	y? 		(d) SrSO <sub>4</sub> is less soluble in water than CaSO <sub>4</sub> .	
	(a) $GeH_2$ $\Box$ (b) $SiH_4$		37.	In which of the following alloys Mg is present?	
••	(c) $B_2H_6$ $\Box$ (d) NaH			(a) Electron	
28.	Sodium oxide cannot be obtained by heating which of t	he		(b) Magnalium	
	following?			(c) Duraluminium	
	(a) NaOCl			(d) Aluminium bronze	
•	* * * * * * * * * * * * * * * * * * * *		38.	KO <sub>2</sub> finds use in oxygen cylinders used for space	and
29.	Portland cement contains the following amount of CaO:			submarines. The fact(s) related to such use of KO2 is/as	re:
	(a) 70-80%			(a) it produces O <sub>2</sub>	
•	(c) 50-60%			(b) it produces O <sub>3</sub>	
30.	•			(c) it absorbs CO <sub>2</sub>	
	(a) electrolysis of fused MgCl <sub>2</sub>			(d) it absorbs N <sub>2</sub> and CO <sub>2</sub> both	
	(b) reduction of MgCl <sub>2</sub> with carbon		39.	In comparison to alkaline earth metals, alkali metals are	:
	(c) electrolysis of aqueous solution of MgCl <sub>2</sub>			(a) more reactive $\square$ (b) less reducing	
	(d) roasting of MgCO <sub>3</sub>			(c) more soft	

40.	Select the wrong statement:	
	(a) The formula of plaster of paris is CaSO <sub>4</sub> ·2H <sub>2</sub> O.	
	(b) MgCO <sub>3</sub> is commonly used in making toothpaste.	
	(c) BeO is a basic oxide.	
	(d) Calcium fluoride is insoluble in water.	

### ASSERTION-REASON TYPE QUESTIONS

Each of the following questions contains statements of **Assertion** (A) and **Reason** (R). Mark the correct answer according to the following code:

- (a) If both (A) and (R) are correct and (R) is the correct explanation of (A).
- (b) If both (A) and (R) are correct but (R) is not the correct explanation of (A).
- (c) If (A) is correct but (R) is incorrect.
- (d) If both (A) and (R) are not correct.
- 41. (A) Hydrogen peroxide in the form of aqueous solution acts as a bleaching agent of delicate materials such as wool, silk, cotton, hair, etc.
  - (R)  $H_2O_2$  acts as a bleaching agent due to its oxidising nature. Coloured material + [O]  $\longrightarrow$  Colourless
- **42.** (A) Normal hydrogen is a mixture of two forms : ortho 75% and para 25%.
  - (R) Pure para-form can be obtained at low temperature but pure ortho-form cannot be obtained.
- **43.** (A) Lithium when heated in the atmosphere of nitrogen forms lithium nitride while other alkali metals do not combine with nitrogen.
  - (R) Lithium is the most reactive alkali metal as its ionisation potential is lowest amongst alkali metals.
- 44. (A) K<sub>2</sub>CO<sub>3</sub> like Na<sub>2</sub>CO<sub>3</sub> can be prepared by Solvay's process.
  - (R) K<sub>2</sub>CO<sub>3</sub> on heating decomposes giving carbon dioxide.
- 45. (A) Alkaline earth metals are harder than alkali metals.
  - (R) The metallic bonding is higher in alkaline earth metals as these possess two electrons in the valence shell.
- **46.** (A) Chemical reduction methods are not applicable for the extraction of alkali and alkaline earth metals.
  - (R) Alkali and alkaline earth metals are themselves strong reducing agents.
- 47. (A) Magnesium and beryllium do not impart colour to flame.
  - (R) Both have high ionisation energies.
- 48. (A) Li<sup>+</sup> has low mobility in aqueous solution.
  - (R) Lithium ion has low tendency of hydration as its size is small.
- **49.** (A)  $H_2O_2$  is a neutral compound.
  - (R)  $H_2O_2$  is an ionic compound.
- **50.** (A) Superoxides are formed by K, Rb and Cs.
  - (R) Superoxides are paramagnetic and coloured.

### **MATRIX MATCHING QUESTIONS**

51. Match Column-I with Column-II:

#### 

52. Match Column-I with Column-II:

# Column-I (a) Sodium (b) Sodium carbonate (c) Potassium (d) Caesium (d) Caesium (e) Potassium (f) Photoelectric cell (g) Nuclear reactor (g) Special thermometers to measure high temperature

**53.** Match Column-I with Column-II:

Column-I	Column-II
(a) NaCl	(p) Sylvine
(b) KCl	(q) Brine
(c) MgCl <sub>2</sub>	(r) Sorel's cement
(d) $CaCN_2 + C$	(s) Rock salt
	(t) Fertilizer

### LINKED COMPREHENSION TYPE

### Passage 1

Lithium and beryllium, the first members of alkali metals and alkaline earth metals respectively, show anomalous behaviour *i.e.*, differ from the rest of the members of their family. The main reasons for their difference are:

- (i) exceptionally small atomic and ionic size
- (ii) high ionisation energy
- (iii) absence of d-orbitals in their valence shell
- (iv) high polarising power of the cations

Answer the following questions:

- 54. Which of the following has the lowest melting point?
  - (a) LiCl (b) NaCl (c) KCl (d) RbCl
- 55. Mg and Li are similar in their properties due to:
  - (a) same e/m ratio
- (b) same electron affinity
- (c) same group
- (d) same ionic potential
- **56.** Which of the following alkali metal ions has the minimum ionic mobility in aqueous solution?
  - (a) Na<sup>+</sup>

(b) K<sup>+</sup>

(c) Li<sup>+</sup>

(d) Cs+

**57.** Be(OH)<sub>2</sub> is:

(a) acidic

(b) basic

(c) amphoteric

(d) neutral

58. Which is least thermally stable?

(a) Li<sub>2</sub>CO<sub>3</sub>

(b) MgCO<sub>3</sub>

(c) BaCO<sub>3</sub>

(d) BeCO<sub>3</sub>

### Passage 2

Hydrogen gas has been considered as one of the alternate sources of energy. The advantage of using hydrogen as a fuel is that it is environmentally clean. The second advantage with hydrogen is that the heat of combustion of hydrogen per gram is higher than any other fuel. But, there are many problems in storing and transportation of hydrogen gas.

Answer the following questions:

59. Which fuel does produce least environmental pollution?

(a) Gasoline

(b) Hydrogen

(c) Wood

(d) Coal

60. Liquid H2 has been used as a rocket fuel because of:

(a) high thrust

(b) small space it occupies

(c) its reaction with oxygen is highly exothermic

(d) all the above are correct

61. Which methods can be used to store hydrogen?

(a) By absorbing hydrogen on activated carbon

(b) Reacting hydrogen with lithium to form LiH

(c) The alloy, LaNi<sub>5</sub>, has high capacity to take up hydrogen

(d) All of the above

### Passage 3

The solubility of an ionic compound in water mainly depends on two factors.

(i) Lattice energy and (ii) hydration energy

Both these factors oppose each other and the resultant of these guides the solubility of the compound in water. If lattice energy has greater value, the solubility is less. In case, hydration energy is more, then the compound is freely soluble in water.

Answer the following questions:

**62.** Compounds of alkaline earth metals are less soluble in water in comparison to alkali metals. This is due to:

(a) their higher ionisation energies

(b) their high lattice energies

(c) their high hydration energies

(d) their increased covalent nature

63. Which of the following is most soluble in water?

(a) MgSO<sub>4</sub>

(b) CaSO<sub>4</sub>

(c) SrSO<sub>4</sub>

(d) BaSO<sub>4</sub>

**64.** BeF<sub>2</sub> is soluble in water whereas fluorides of other alkaline earth metals are insoluble because of :

(a) ionic nature of BeF<sub>2</sub>

(b) covalent nature of BeF2

(c) greater hydration energy of Be<sup>2+</sup> ion

(d) greater lattice enrgy of Be<sup>2+</sup> ion

### **INTEGER ANSWER TYPE**

65. How many alkali metals are known?

66. How many neutrons are present in tritium atom?

67. How many isotopes of hydrogen are known?

**68.** In water, each H<sub>2</sub>O molecule is surrounded by ...... neighbouring H<sub>2</sub>O molecules randomly by hydrogen bonding.

69. What is the degree of hardness of a sample of water containing 10.8 mg of MgSO<sub>4</sub> (Mol. mass 120) per kg of water?

**70.** Of all the alkali metals, only sodium and potassium are found in abundance in nature *i.e.*, they are ....th and ....th most abundant elements by weight in earth's crust.

**71.** How many water molecules are present as water of crystallisation in the molecule of gypsum?

### Answers with Hints

(b) Both Ca and CaH<sub>2</sub> on reaction with water evolve hydrogen gas.
 Ca + 2H<sub>2</sub>O → Ca(OH)<sub>2</sub> + H<sub>2</sub>
 CaH<sub>2</sub> + 2H<sub>2</sub>O → Ca(OH)<sub>2</sub> + 2H<sub>2</sub>

**2.** (d)

 $K_2Cr_2O_7 + H_2SO_4 + 4H_2O_2 \longrightarrow 2CrO_5 + K_2SO_4 + 5H_2O$ Chromium
peroxide(blue)

3. (a)  $NaNH_2 + C \xrightarrow{Heat} NaCN + H_2 \uparrow$ 

 $\begin{array}{lll} \textbf{4.} & \text{(c)} & \text{Alkali metals carbonates except } \text{Li}_2\text{CO}_3 \text{ do not decompose on} \\ & \text{heating. The thermal stability of alkaline earth metals carbonates} \\ & \text{increases from top to bottom.} \end{array}$ 

5. (c) Smaller the ion, higher is degree of hydration *i.e.*, high is hydration enthalpy. Thus, the hydration enthalpies decrease as the size of ion increases from Li<sup>+</sup> to Cs<sup>+</sup>.

**6.** (b) % strength =  $\frac{17}{56}$  × volume strength =  $\frac{17}{56}$  × 10 = 3.036 *i.e.*, 30.36 g/L

7. (d)  $H_2O_2 + O_3 \longrightarrow H_2O + 2O_2$ 1 vol 2 vol

8. (b) Hydrogen < Deuterium < Tritium  $_{20.60 \text{ K}}$  (melting point)

**9.** (d)

- 10. (a) KI +  $I_2 \longrightarrow KI_3 (I_3^-)$
- 11. (a)  $NaNH_2 + H_2O \longrightarrow Na^+(aq.) + OH^- + NH_3$
- 12. (b)  $M(HCO_3)_2 + CaO \longrightarrow \underbrace{MCO_3 + CaCO_3}_{Insoluble} + H_2O$

$$MCl_2 + Na_2CO_3 \longrightarrow MCO_3 + 2NaCl$$
Insoluble Soluble

$$MSO_4 + Na_2CO_3 \longrightarrow MCO_3 + Na_2SO_4$$
Insoluble Soluble

13. (c) 
$$2\text{NaHCO}_3 \longrightarrow \text{Na}_2\text{CO}_3 + \text{CO}_2 + \text{H}_2\text{O}_2$$
(Y) (Y)

$$Na_2CO_3 + H_2O + CO_2 \longrightarrow 2NaHCO_3$$
(X)
(Y)

14. (d) BeSO<sub>4</sub> is soluble in water. BeO becomes inert on heating. Be(OH)<sub>2</sub> is insoluble and reacts with NaOH. The product is soluble in water.

$$Be(OH)_2 + 2NaOH \longrightarrow Na_2BeO_2 + 2H_2O$$
Soluble

- 15. (b) Ionic mobility depends on the size of ion. The ionic size in case of hydrated cation is  $K_{aq}^+ < Na_{aq}^+ < Li_{aq}^+$ .
- 16. (a) The maximum value of oxidation potential of lithium makes it strongest reducing agent amongst alkali metals.
  The values of oxidation potentials increase from top to bottom in IIA group. Thus, Ba is a strong oxidising agent.

17. (a) 
$$CaCO_3 \longrightarrow CaO + CO_2$$

$$\downarrow H_2O \qquad \qquad Calcurless$$

$$CO_2 \longrightarrow Ca(OH)_2 \longrightarrow Ca(HCO_3)_2 \xrightarrow{Heat} CaCO_3$$

$$(B) \qquad (C) \qquad (A)$$

- 18. (c) (BaSO<sub>4</sub> + ZnS) is a white pigment known as lithophone.
- **19.** (c) Na + (x + y) NH<sub>3</sub>  $\longrightarrow$  Na<sup>+</sup>(NH<sub>3</sub>)<sub>x</sub> +  $e^{-1}$ (NH<sub>3</sub>)<sub>y</sub>
- 20. (b)
- 21. (d)  $CaO + H_2O \longrightarrow Ca(OH)_2$
- 22. (d) 23. (b)
- 24. (c) 'X' is oxygen.  $H_2O$  is amphoteric.  $CaH_2 + 2H_2O \longrightarrow Ca(OH)_2 + 2H_2$
- 25. (d) Water acts as a proton donor when it reacts with NH<sub>3</sub>.
- **26.** (b)
- 27. (d) NaH is an ionic hydride. In molten state, it conducts electricity.

28. (d) 
$$2\text{NaOCl} \longrightarrow 2\text{NaCl} + \text{O}_2$$
  
 $2\text{NaHCO}_3 \longrightarrow \text{Na}_2\text{CO}_3 + \text{H}_2\text{O} + \text{CO}_2$   
 $2\text{NaNO}_3 \longrightarrow 2\text{NaNO}_2 + \text{O}_2$ 

- 29. (c) 30. (a)
- **31.** (a, c, d)
- 32. (a, d) The reactivity of hydrogen towards halogens is in the order  $F_2 > Cl_2 > Br_2 > I_2$ . Atomic hydrogen reduces acidified KMnO<sub>4</sub> to manganous salt.

33. (a, c) 
$$Cl_2 + 2NaOH \longrightarrow NaCl + NaClO + H_2O$$

$$3Cl_2 + 6NaOH \longrightarrow 5NaCl + NaClO_3 + 3H_2O$$

34. (a, b, c) 
$$3Ca + N_2 \longrightarrow Ca_3N_2$$
$$3Mg + N_2 \longrightarrow Mg_3N_2$$
$$6Li + N_2 \longrightarrow 2Li_3N$$

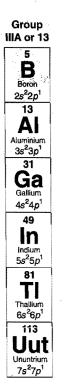

35. (b, d) 
$$Ba(NO_3)_2 \longrightarrow BaO + 2NO_2 + \frac{1}{2}O_2$$
$$2LiNO_3 \longrightarrow Li_2O + 2NO_2 + \frac{1}{2}O_2$$

- 36. (c, d) 37. (a, b, c) 38. (a, c) 39. (a, c, d)
- 40. (a, c) The formula of plaster of paris is CaSO<sub>4</sub>· ½ H<sub>2</sub>O<sub>4</sub>.
  BeO is an amphoteric oxide.
- 41. (a) 42. (b) 43. (c) 44. (d) 45. (a) 46. (a) 47. (a)
- **48.** (c) **49.** (d) **50.** (b)
- **51.** (a-p, r); (b-p); (c-q, t); (d-q, s)
- **52.** (a-p, s, t); (b-p, q); (c-r, t); (d-r)
- **53.** (a-q, s); (b-p, t); (c-r); (d-t)
- **54.** (a) Due to high polarising power of Li<sup>+</sup> ion, LiCl shows somewhat covalent nature.
- 55. (d)
- **56.** (c) Li<sup>+</sup> ion being smallest in size has high degree of hydration.
- 57. (c) Be(OH)<sub>2</sub> combines both with acid and alkali.
- 58. (d) 59. (b) 60. (d) 61. (d)
- **62.** (b) The cations have small ionic size and double the charge in comparison to alkali metal ions. Therefore, their lattice energies are high.
- **63.** (a) **64.** (c) **65.** (6) **66.** (2) **67.** (3) **68.** (4)
- 69. (9) 10.8 mg of MgSO<sub>4</sub> is present in 10<sup>3</sup> g of water.

Thus, 
$$10^6$$
 g of water contains = 10800 mg of MgSO<sub>4</sub>  
= 10.8 g of MgSO<sub>4</sub>  
 $120$  g MgSO<sub>4</sub> =  $100$  g of CaCO<sub>3</sub>

So, 
$$10.8 \text{ g of MgSO}_4 = \frac{100 \text{ g of CaCO}_3}{120} \times 10.8 = 9 \text{ g CaCO}_3$$
  
Hardness of water = 9 ppm

### 8.1 GENERAL CHARACTERISTICS OF GROUP IIIA OR 13 ELEMENTS

Group IIIA or 13 of the long form of the periodic table consists of six elements—boron, aluminium, gallium, indium, thallium and ununtrium. These are p-block elements as the last differentiating electron enters np orbital. The configuration of the outermost energy shell is  $ns^2$   $np^1$ , i.e., this group marks the beginning of the p-block elements. Since the members of this group possess three electrons in the outermost or in their valency shell, they have many similarities in their properties. However, the penultimate shell (next to the outermost) contains  $s^2$ -grouping in boron,  $s^2p^6$  (8 electrons) in aluminium and  $s^2p^6d^{10}$  (18 electrons) in other elements (Ga, In, Tl and Uut). This shows why boron differs from aluminium and both boron and aluminium having noble gas kernel differ from other four elements. The **electronic configuration** of these elements is given below:

Element	At. No.		Electronic configuration	Inert gas core
В	5	2, 3	$1s^2$ , $2s^2 2p^1$	[He] $2s^2 2p^1$
A1	13	2, 8, 3	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^1$	[Ne] $3s^2 3p^1$
Ga	31	2, 8, 18, 3	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^1$	[Ar] $3d^{10}$ , $4s^2 4p^1$
In	49	2, 8, 18, 18, 3	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ , $5s^2$ $5p^4$	[Kr] $4d^{10}$ , $5s^2$ $5p^1$
<b>T</b> 1	81	2, 8, 18, 32, 18, 3	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ $4f^{14}$ , $5s^2$ $5p^6$ $5d^{10}$ , $6s^2$ $6p^1$	[Xe] $4f^{14}$ , $5d^{10}$ , $6s^2$ $6p$
Uut	113	2, 8, 18, 32, 32, 18, 3	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ $4f^{14}$ , $5s^2$ $5p^6$ $5d^{10}$ $5f^{14}$ ,	[Rn] $5f^{14}$ , $6d^{10}$ , $7s^2$ $7p$
			$6s^2 6p^6 6d^{10}, 7s^2 7p^1$	

The members of this group are less metallic in comparison to elements of IA (alkali metals) and IIA (alkaline earth metals) groups. Boron is regarded as a semi-metal. It is closer to non-metals than metals in its properties. Aluminium and rest of the elements are metallic in nature. General characteristics of these elements\* are discussed below:

- 1. Abundance and occurrence: Aluminium is the most abundant metal and third most abundant element (after oxygen and silicon) by mass in the earth's crust. The most important ore of aluminium is bauxite. Boron is fairly rare element but it is well known because it occurs as concentrated deposits of borax, kernite and tourmaline crystal. Gallium is twice as abundant as boron, but indium and thallium are much less common. All the three elements (Ga, In and Tl) occur as sulphides in traces in zinc and lead sulphide ores.
- **2. Atomic and ionic radius:** The atomic radius increases from boron to thallium. Ionic radius  $(M^{3+})$  also increases.

However, gallium has an abnormal value of atomic radius, which is lower than that of aluminium.

	В	Al	Ga	In	Tl
Atomic radius (pm)	85	143	135	167	170
(Metallic)					
Ionic radius $M^{3+}$ (pm)	27	53.5	62	80.0	88.5

[There is no evidence for the existence of B<sup>3+</sup> and the value of ionic radius is an estimate.]

The sharp increase of atomic radius of Al is due to greater screening effect in aluminium due to the presence of eight electrons in the penultimate shell than in boron which has two electrons in the penultimate shell. Thus, outermost electrons in boron experience greater nuclear attraction than in aluminium resulting thereby smaller atomic radii in boron in comparison to aluminium.

Ga, In and Tl follow after a row of ten transition elements. Thus, there are ten d electrons in the penultimate shell which are less efficient in shielding the nuclear charge and outer electrons are firmly held by nucleus. Thus, atoms with a  $d^{10}$  inner shell are smaller than would otherwise be expected.

The large difference in size between B and Al results in many differences in properties.

The smaller value of gallium in comparison to aluminium is due to the fact that in going from Al to Ga the penultimate d-orbitals are filled in the first d-block series from Sc(21) to Zn (30). The d-electrons do not screen the nuclear charge in an effective manner and therefore, the electrons in the outermost shell of gallium experience more force of attraction towards nucleus than aluminium, causing thereby decrease in atomic radius.

The atomic and ionic radii of group 13 elements are smaller than the corresponding elements of group 1 and 2 in the same period.

This is due to the fact that effective nuclear charge increases and electrons are pulled inwards resulting in a decrease in atomic size.

In isoelectronic species, the ionic size decreases with increase in atomic number, *i.e.*, *z/e* ratio.

$$Na^{+}$$
 >  $Mg^{2+}$  >  $Al^{3+}$  (102 pm) (72 pm) (53.5 pm)

**3. Density:** Density increases from boron to thallium. However, boron and aluminium have comparatively low values. This is due to their lower atomic masses as compared to gallium, indium and thallium.

**4. Melting and boiling points:** The elements of this group do not show a regular change in their melting points with increase in atomic number. The melting point decreases from B to Ga and then increases.

The high melting point of boron is due to the fact that it exists as a giant covalent polymer in both solid and liquid state. The elements Al, In and Tl all have close-packed metal structures. Gallium has an unusual structure. It consists of only Ga<sub>2</sub> molecules. It has, thus, low melting point. It exists as liquid up to 2000°C and hence used in high temperature thermometry.

However, the boiling points of the elements of IIIA group follow a regular decrease from boron to thallium. This shows that the strength of the bonds holding the atoms in liquid state decreases from boron to thallium.

- **5. Ionisation energy or ionisation enthalpies :** The following trends are observed:
- (i) The first ionisation energies of group 13 elements are lower than the corresponding elements of group 2, *i.e.*, alkaline earth metals in the same period. However, second ionisation energies of group 13 elements are higher in comparison to corresponding alkaline earth metals.
- (ii) On moving down the group from boron to thallium, a regular decreasing trend (expected) in the ionisation energy values is not observed. The ionisation energy decreases from B to Al, increases in Ga and again decreases in In. The value of ionisation energy of Tl is higher than In.
- (iii) The second and third ionisation energies for the elements are successively higher.

<sup>\*</sup>Thallium, is known as **Duckbill platypus** as it shows similarities with many other elements. Ununtrium, the last member of this group, is a synthetic and radioactive element. Very little is known about its characteristics.

The values o	f first, s	econd	and 1	third	ionisation	energy
of group 13 ele	ments a	are tab	ulate	d bel	ow:	

Til		Ionisati	on energy (l	kJ mol <sup>-1</sup> )
Element	1st	2nd	3rd	Sum of three
В	801	2427	3659	6887
. Al	577	1816	2744	5137
Ga	579	1979	2962	5520
Ĭn	558	1820	2704	5082
T1	589	1971	2877	5437

The elements of group 13 have  $ns^2np^1$ -grouping in the outermost energy shell. For the first ionisation energy, the electron has to be removed from the p-orbital in case of group 13 elements while in alkaline earth metals  $(ns^2)$ , the s-electron of the same energy shell has to be removed. Since, s-electron is nearer to nucleus in comparison to p-electron, it is more firmly held than p-electron due to strong attractive force. Hence, the removal of p-electron is easier and, therefore, the first ionisation energy values of group 13 elements are lower than the corresponding alkaline earth metals.

After the removal of p-electron, the elements of group 13 acquire  $ns^2$ -configuration while alkaline earth metals acquire  $ns^1$ -configuration. It is easier to remove electrons from  $ns^1$  in comparison to  $ns^2$  in the same energy shell. Hence, the second ionisation energy values of group 13 elements are higher than the corresponding alkaline earth metals.

The first ionisation energy of boron is highest in the group since, its size is smallest and screening effect is lowest. The sharp decrease from B to Al is due to appreciable increase in atomic size and the screening effect of s and p-electrons of the penultimate energy shell. In case of Ga, there are ten d-electrons in the penultimate energy shell which screen the nuclear charge less effectively and, thus, the outer electron is held firmly by the nucleus. As a result, the ionisation energy remains nearly the same as that of aluminium. In case of In, the number of d-electrons and their shielding effect remain the same as in gallium. The ionisation energy, however, decreases in indium due to increase in atomic size from Ga to In. The increase in ionisation energy from In to Tl is due to poor screening effect of 14f-electrons present in the inner energy shell.

After the loss of first electron, the effective nuclear charge increases with the result that decrease in ionic size occurs and thus, more and more energies are required for the removal of second, third and subsequent electrons.

$$IE_{\rm I} < IE_{\rm II} < IE_{\rm III} < IE_{\rm IV}$$

Since, the sum of first, second and third successive ionisation energies of the elements of this group is very high, these elements have little tendency to form trivalent ions. **6.** Electropositive or metallic character: The elements of group 13 are less electropositive as compared to the elements of groups 1 and 2 (s-block elements). This is due to their small size and high ionisation energy.

The electropositive character increases from boron to aluminium and then decreases from aluminium to thallium. Boron having very high ionisation energy is regarded as a semimetal. It is more closer to non-metals. Aluminium is a metal and is most electropositive. The increase in electropositive nature from B to Al is due to increased atomic size. The remaining three elements Ga, In and Tl are less electropositive and less metallic than aluminium and there is decrease from Ga to Tl. The presence of  $d^{10}$ -electrons in the penultimate shell in gallium and indium and  $d^{10}$  and  $f^{14}$ -electrons in the inner shells of thallium do not shield the nuclear charge effectively and therefore, these elements are less electropositive. Boron is a bad conductor while aluminium is a very good conductor of electricity. Gallium, indium and thallium also conduct electricity.

- 7. Oxidation potential (Reducing nature): Boron does not form positive ions in aqueous solution and thus has low value of oxidation potential. The oxidation potential values of other elements of the group are quite high. This is due to high heats of hydration on account of small size of trivalent cations  $(M^{3+})$ . [Aluminium is a strong reducing agent and in fact better than carbon. This is due to low ionisation energy of aluminium than carbon.]
- **8.** Oxidation states: It is in group 13 that we first encounter elements possessing more than one oxidation state. As  $s^2p^1$  grouping is present in the outermost energy shell of the elements of the group IIIA, the expected oxidation states are +3 and +1. Boron shows +3 oxidation state in all its compounds. Other members show +3 and +1 oxidation states. The stability of +1 oxidation state increases from aluminium to thallium and the stability of +3 oxidation state decreases from aluminium to thallium, *i.e.*, +3 is more important oxidation state for Al, Ga and In whereas +1 oxidation state is more important for Tl.

Relative stability of  $M^+$  and  $M^{3+}$  ions may be give as:

$$B^{3+} > Al^{3+} > Ga^{3+} > In^{3+} > Tl^{3+}$$
  
 $B^{+} < Al^{+} < Ga^{+} < In^{+} < Tl^{+}$ 

 $\mathrm{Tl}^+$  ions are more stable than  $\mathrm{Tl}^{3+}$  ions and thus,  $\mathrm{Tl}^{3+}$  ions change to  $\mathrm{Tl}^+$  ions thereby acting as oxidising agents.

$$Tl^{3+}$$
 compounds + 2e  $\longrightarrow$   $Tl^{+}$  compounds (Less stable oxidising agent) (More stable reducing agent)

[Tl(I) compounds resemble alkali metal compounds. Tl(OH) like NaOH is soluble in water and the solution is strongly alkaline. Like alkali metals,  $Tl_2SO_4$  forms a double sulphate with  $Al_2(SO_4)_3$ .

 $K_2SO_4\cdot Al_2(SO_4)_3\cdot 24H_2O;$   $Tl_2SO_4\cdot Al_2(SO_4)_3\cdot 24H_2O$   $Tl_2CO_3$  like  $Na_2CO_3$  is soluble in water.]

In case of Ga and In, +3 oxidation is more stable than +1 oxidation state. The salts of both Ga<sup>+</sup> and In<sup>+</sup> undergo disproportionation reactions in aqueous solutions.

$$\begin{array}{ccc}
+1 & 0 & +3 \\
3GaX & \longrightarrow & 2Ga + GaX_3 \\
3InX & \longrightarrow & 2In + InX_3
\end{array}$$

The decreasing stability of +3 is due to increase in inert pair effect.

Gallium appears to show +2 oxidation state in GaCl<sub>2</sub>. However, it is believed that this compound has the structure Ga[GaCl<sub>4</sub>] which contains univalent and trivalent gallium ions.

$$Ga[GaCl4] = Ga+[Ga3+Cl4]-$$

- **9. Nature of bonding:** The following points suggest that bonding in the compounds of group IIIA elements should be covalent.
- (a) Small size of ions and their high charge are responsible for high polarisation.
  - (b) The sum of first three ionisation energies is very large.
- (c) The electronegativity values are higher and thus, when reacting with other elements the difference is not large.

Boron is considerably smaller than other members and its ionisation potential is maximum and hence it always shows covalency. Many simple compounds of the other elements such as AlCl<sub>3</sub> and GaCl<sub>3</sub> are covalent when anhydrous. However, Al, Ga, In and Tl all form metal ions in solution. The change from covalent to ionic occurs because the ions are highly hydrated and the amount of hydration energy evolved exceeds the ionisation energy. For example, AlCl<sub>3</sub> releases 5808 kJ mol<sup>-1</sup> of hydration energy which exceeds the ionisation energy  $(Al \rightarrow Al^{3+} = 5137 \text{ kJ mol}^{-1})$ , so AlCl<sub>3</sub> ionises. The hydrated aluminium compounds which are regarded as ionic do not contain the aluminium ion,  $Al^{3+}$ , as such but the hexa-aquaaluminium ion,  $[Al(H_2O)_6]^{3+}$ . The relative stability of [M(H<sub>2</sub>O)<sub>6</sub>]<sup>3+</sup> ions decreases on moving down the group. Thallium compounds are ionic. Monovalency of thallium is due to increasing reluctance of the paired ns electrons to form bonds. [Such inertness of ns electrons is observed when the electrons are in fifth or higher energy shell and their removal does not form a cation whose electronic configuration is that of an inert gas. This behaviour is termed as inert pair effect.]

In trivalent state, the number of electrons around the central atom in a molecule such as BCl<sub>3</sub>, BF<sub>3</sub>, AlCl<sub>3</sub>, etc., will be only six and thus behave as **electron deficient molecules**. They act as **Lewis acids**.

$$Cl_3B + : NH_3 \longrightarrow Cl_3B \longleftarrow NH_3$$
Base

However, Lewis acid character decreases down the group as the atomic size increases.

The electron deficient compounds remove their electron deficiency by :

(i) **Back-bonding:** In B $X_3$ , B is  $sp^2$  hybridised *i.e.*, it has one p-orbital vacant. X-atom has filled p-orbital. They overlap resulting into  $\pi$ -bonding.

(ii) Coordination with Lewis bases: B has vacant p-orbital which accepts electron pair from donor.

For example, 
$$BF_3 + F^- \longrightarrow BF_4$$
  
 $Al(OH)_3 + OH^- \longrightarrow Al(OH)_4^-$ 

(iii) **Polymerization :** Some compounds remove electron deficiency by dimerization.

For example, 
$$2AlCl_3 \longrightarrow Al_2Cl_6$$

Note: In aluminium compounds back bonding is not possible due to following reasons:

- (a) p-orbital of Al is large, so p-p overlap is not effective.
- (b) 8-electron core in Al causes larger repulsion, thus destabilising back bonding.
- **10.** Complex formation: Group IIIA elements form complexes much more readily than the s-block elements, because of their smaller size, increased charge and availability of vacant orbitals.
- 11. Reactivity towards air: Boron exists in two forms (a) crystalline and (b) amorphous. Boron is unreactive towards air in crystalline state. Amorphous boron on heating in air form boron trioxide. At high temperatures, it also combines with nitrogen.

$$4B + 3O_2 \xrightarrow{-700^{\circ}C} 2B_2O_3$$

$$2B + N_2 \xrightarrow{\text{High temp.}} 2BN$$

Aluminium is not affected by dry air. However, a thin oxide layer\* is formed on the surface of aluminium metal in moist air. It protects the metal from further attack. It also forms nitride with nitrogen at high temperatures.

$$4Al + 3O_2 \xrightarrow{\text{Heat}} 2Al_2O_3$$
$$2Al + N_2 \xrightarrow{\text{High temp.}} 2AlN$$

Gallium and indium are not affected by air. Thallium forms an oxide layer on its surface. Thallium is preserved under oil or by smearing with vaseline.

12. Reactivity towards water: Boron is not affected by water or steam, however, steam reacts at red heat. Aluminium decomposes cold water if the oxide layer is not present on its surface.

$$2B + 3H2O \longrightarrow B2O3 + 3H2$$
$$2Al + 3H2O \longrightarrow Al2O3 + 3H2$$

<sup>\*</sup>The oxide film on the surface of aluminium is so useful that in industry it is purposely increased by an electrolytic process called **anodising.** Anodised cooking vessels are used now as non-stick cookware.

The tendency of accepting electron pair is also observed in the halides of aluminium and other members (act as Lewis acids). However, this tendency decreases with the increase in size of the cation. They form complex halides of the type  $[MX_6]^{3-}$  where the M-atom extends its coordination number to 6 by the use of d-orbitals. These halides do not show back bonding due to increase in the size of the element. However, they make use of vacant p-orbital by coordinate bond, i.e., complete their octet by forming dimers.

Dimer forms exist in vapour state and in non-polar solvents. Dimer structure disappears when the halides are dissolved in water. This is due to high hydration energy when  $[M(H_2O)_6]^{3+}$  and  $3X^-$  ions are formed making the solution as good conductor of electricity.

The solution becomes acidic owing to hydrolysis.

$$AlCl_3 + 9H_2O \longrightarrow [Al(H_2O)_6](OH)_3 + 3H^+ + 3Cl^-$$

In addition to trihalides, these elements form di as well as monohalides. Boron forms dihalides,  $B_2X_4$ .

$$X$$
  $B-B$   $X$ 

In solid state,  $B_2X_4$  has planar structure but in liquid and vapour state, it has non-eclipsed structure.

Tetrahalides can be synthesised by heating trihalides with mercury at low pressure.

$$2BCl_3 + 2Hg \xrightarrow{Electric \ discharge} B_2Cl_4 + Hg_2Cl_2$$

Gallium and indium also form dihalides. Gallium dihalide is more properly represented as  $Ga^{+}[GaCl_{4}]^{-}$  showing gallium in +1 and +3 oxidation states.

The elements of IIIA in gaseous state form monohalides, MX. These are very unstable halides and they are covalent in nature. The covalent nature decreases and thallium halides are ionic in nature.

### 8.2 ABNORMAL BEHAVIOUR OF BORON

Boron differs markedly from the rest of the members of group IIIA and this abnormal behaviour is illustrated in the following properties:

(i) Boron has very small atomic radii, hence greater nuclear attraction on the outermost electrons. It has very high ionisation energy. This gives boron distinctly **nonmetallic** character while the rest are metals.

- (ii) Boron has maximum covalency of four due to nonavailability of d-orbitals while the rest have maximum covalency of six.
  - (iii) Boron alone exhibits allotropy.
- (iv) Boron shows +3 oxidation state while others can show +1 and +3 oxidation states.
- (v) Boron does not form cations in aqueous solution as the hydration energy is less than sum of three successive ionisation energies.
- (vi) Boron halides are monomeric while the halides of the other elements are dimeric. It does not show inert pair effect.
- (vii) Boron forms a number of volatile hydrides which are electron deficient compounds. Others form only one polymeric hydride. Thallium does not form hydride.
- (viii) Boron does not decompose water or steam while other elements decompose hot water or steam.
- (ix) The oxide of boron, B<sub>2</sub>O<sub>3</sub>, is acidic in nature while the similar oxides of the other elements are either amphoteric or basic.
- (x) Boron is not attacked by non-oxidising acids while other elements are attacked.
- (xi) Boron dissolves in conc. HNO<sub>3</sub> forming H<sub>3</sub>BO<sub>3</sub>. The other elements become passive specially Al and Ga.
- (xii) Boron combines with metals and form borides while other elements do not combine. They can form alloys.

### 8.3 COMPARISON OF BORON AND ALUMINIUM

Since both boron and aluminium have three electrons in their valency shell, they have many similarities in their properties.

B 5 2, 3 
$$1s^2$$
,  $2s^2$   $2p^1$  [He]  $2s^2$   $2p^1$   
Al 13 2, 8, 3  $1s^2$ ,  $2s^2$   $2p^6$ ,  $3s^2$   $3p^1$  [Ne]  $3s^2$   $3p^1$ 

On the other hand, they have different number of electrons in their penultimate shell (2 in boron and 8 in aluminium) and consequently show many dissimilarities also.

### Points of Similarities

- (i) Electronic configuration: Both have same number of electrons in the outermost shell (valency shell).
- (ii) Valency: Both show trivalency. They do not show variable valency because their kernels are stable. It is difficult to get B<sup>3+</sup> because large amount of energy is required and therefore boron forms tri-covalent compounds. Aluminium also forms covalent compounds. It can, however, form electrovalent compounds when it combines with strong electron accepting atoms or groups. The size of Al<sup>3+</sup> ion is very small. On account of small size and high charge, it has high polarising power. This accounts for a covalent character even in the case of electrovalent compounds, for example, AlCl<sub>3</sub>, AlBr<sub>3</sub> and AlI<sub>3</sub> have covalent nature.
- (iii) Oxidation state: Both show common oxidation state of +3 in majority of their compounds.

Compound	Oxid. state	Compound	Oxid. state
$B_2O_3$	. +3	$Al_2O_3$	+3
BCl <sub>3</sub>	+3	AlCl <sub>3</sub>	+3
$H_3BO_3$	+3	$Al(OH)_3$	+3
$Na_2B_4O_7$	+3	NaAlO <sub>2</sub>	+3

Boron, however, also shows an oxidation state of -3 in the metal borides, e.g., in  $Mg_3B_2$  (magnesium boride), oxidation state of boron is -3.

(iv) Action of alkalies: Both dissolve in alkalies and evolve hydrogen.

$$2B + 6NaOH \longrightarrow 2Na_3BO_3 + 3H_2$$
 Sodium borate 
$$2Al + 2NaOH + 2H_2O \longrightarrow 2NaAlO_2 + 3H_2$$
 Sodium meta aluminate

(v) Action of concentrated  $H_2SO_4$ : Both react with conc.  $H_2SO_4$  and evolve sulphur dioxide,  $SO_2$ .

$$[H_2SO_4 \longrightarrow H_2O + SO_2 + O] \times 3$$

$$2B + 3O \longrightarrow B_2O_3$$

$$B_2O_3 + 3H_2O \longrightarrow 2H_3BO_3$$

$$2B + 3H_2SO_4 \longrightarrow 2H_3BO_3 + 3SO_2$$

$$6H_2SO_4 + 2A1 \longrightarrow Al_2(SO_4)_3 + 3SO_2 + 6H_2O$$

(vi) Formation of oxides: Both form oxides of the type  $M_2O_3$  when heated in atmosphere of oxygen at high temperature.

$$4B + 3O_2 \xrightarrow{700^{\circ}C} 2B_2O_3$$
 (Boron oxide or boric anhydride)

$$4Al + 3O_2 \xrightarrow{800^{\circ}C} 2Al_2O_3$$
 (Aluminium oxide or alumina)

The oxides are amphoteric in nature. B<sub>2</sub>O<sub>3</sub> is more acidic and less basic while Al<sub>2</sub>O<sub>3</sub> is more basic and less acidic.

$$\begin{array}{c} B_2O_3 + 6NaOH \longrightarrow 2Na_3BO_3 + 3H_2O \\ Al_2O_3 + 6HCl \longrightarrow 2AlCl_3 + 3H_2O \\ Al_2O_3 + 2NaOH \longrightarrow 2NaAlO_2 + H_2O \end{array}$$

(vii) Formation of chlorides: Both form trichlorides either by passing chlorine over heated boron or aluminium or by passing chlorine over heated mixture of their oxides and charcoal.

$$2B + 3Cl2 \longrightarrow 2BCl3$$

$$2Al + 3Cl2 \longrightarrow 2AlCl3$$

$$B2O3 + 3C + 3Cl2 \longrightarrow 2BCl3 + 3CO$$

$$Al2O3 + 3C + 3Cl2 \longrightarrow 2AlCl3 + 3CO$$

Trichlorides are hydrolysed by water, i.e., both show covalent nature.

$$BCl_3 + 3H_2O \longrightarrow H_3BO_3 + 3HCl$$
  
 $AlCl_3 + 3H_2O \longrightarrow Al(OH)_3 + 3HCl$ 

Halides act as Lewis acids whenever donor molecules (Lewis bases) are available.

$$H_3N \longrightarrow BCl_3, H_3N \longrightarrow AlCl_3$$

(viii) Formation of nitrides: Both form nitrides of the type MN when heated in the atmosphere of nitrogen or ammonia.

$$2B + N_2 \longrightarrow 2BN$$

$$2B + 2NH_3 \longrightarrow 2BN + 3H_2$$

$$2Al + N_2 \longrightarrow 2AlN$$

$$2Al + 2NH_3 \longrightarrow 2AlN + 3H_2$$

The nitrides undergo hydrolysis with steam.

AlN + 3H<sub>2</sub>O 
$$\longrightarrow$$
 Al(OH)<sub>3</sub> + NH<sub>3</sub> Aluminium hydroxide

(ix) Formation of sulphides: Both form sulphides of the type  $M_2S_3$  when heated with sulphur.

$$2B + 3S \longrightarrow B_2S_3$$
  
 $2Al + 3S \longrightarrow Al_2S_3$ 

Sulphides are hydrolysed with water.

$$\begin{array}{ll} B_2S_3 + 6H_2O & \longrightarrow 2H_3BO_3 + 3H_2S \\ Al_2S_3 + 6H_2O & \longrightarrow 2Al(OH)_3 + 3H_2S \end{array}$$

(x) Formation of alkyl compounds: Both form similar types of alkyl compounds, such as B(CH<sub>3</sub>)<sub>3</sub>, Al(CH<sub>3</sub>)<sub>3</sub>.

$$2BCl_3 + 3Zn(CH_3)_2 \longrightarrow 2B(CH_3)_3 + 3ZnCl_2$$
  
 $2Al + 3Hg(CH_3)_2 \longrightarrow 2Al(CH_3)_3 + 3Hg$ 

(xi) Reducing nature: Both act as powerful reducing agents.

$$\begin{array}{ccc} 4B + 3CO_2 & \longrightarrow 2B_2O_3 + 3C \\ 3SiO_2 + 4B & \longrightarrow 2B_2O_3 + 3Si \\ 2Al + Cr_2O_3 & \longrightarrow Al_2O_3 + 2Cr \\ 2Al + Fe_2O_3 & \longrightarrow Al_2O_3 + 2Fe \\ 4Al + 3CO_2 & \longrightarrow 2Al_2O_3 + 3C \end{array}$$

(xii) Action of steam: Boron reacts with steam at red heat liberating hydrogen.

$$2B + 3H_2O \longrightarrow B_2O_3 + 3H_2$$

Aluminium decomposes boiling water.

$$2Al + 6H2O \longrightarrow 2Al(OH)3 + 3H2$$

### Dissimilarities between Boron and Aluminium

Boron and aluminium show dissimilarities in properties due to difference in their electronic configuration, size and ionisation potential. Main points of difference are given in the table.

	<u> </u>	
Boron	Aluminium	
(i) Boron is a non-metal.	Aluminium is a metal.	
(ii) It is a bad conductor of heat and electricity.	It is a good conductor of heat and electricity.	
(iii) It has high melting point (m.pt. 2300°C).	It has low melting point (m.pt. 660°C).	
(iv) Boron shows allotropy. The allotropic forms are crystalline boron	Aluminium does not show allotropy.	15
and amorphous boron,		:

(v) It does not react with dil. HCl and dil. H2SO4.

(vi) It is attacked by conc. HNO3.

$$[2HNO_{3} \longrightarrow H_{2}O + 2NO_{2} + O] \times 3$$

$$2B + 3O \longrightarrow B_{2}O_{3}$$

$$B_{2}O_{3} + 3H_{2}O \longrightarrow 2H_{3}BO_{3}$$

$$2B + 6HNO_{3} \longrightarrow 2H_{3}BO_{3} + 6NO_{2}$$
or
$$B + 3HNO_{3} \longrightarrow H_{3}BO_{3} + 3NO_{2}$$

- (vii) Borates are very stable.
- (viii) BCl3 is a fuming liquid.
- (ix) It combines with metals. The compounds formed are called borides.  $3Mg+2B \longrightarrow Mg_3B_2$
- (x) B(OH)<sub>3</sub> is a weak acid.
- (xi) The maximum covalency of boron is four and is shown in compounds like potassium fluoroborate, K[BF<sub>4</sub>].
- (xii) Boron forms a number of hydrides like  $B_2H_6$ ,  $B_4H_{10}$ ,  $B_{10}H_{14}$ , etc. These are covalent and electron deficient in nature.
- (xiii) Boron trihalides exist as discrete molecules, *i.e.*, monomeric in nature, BX<sub>3</sub>
- (xiv) It forms covalent compounds only.
- (xv) It forms a covalent carbide, B<sub>4</sub>C.

### DIAGONAL RELATIONSHIP OF BORON AND SILICON

Following are the properties where boron and silicon show close resemblance:

- (i) Both boron and silicon are non-metals. Both have high melting points  $[B = 2300^{\circ}C; Si = 1410^{\circ}C]$ , high ionisation energies (B = 8.3 eV, Si = 8.20 eV) and are bad conductors of electricity at normal temperature. However, the conductance improves as the temperature increases. Hence, both are semiconductors.
- (ii) Both have nearly equal densities, electronegativities [Density  $B = 3.30 \text{ g mL}^{-1}$ ;  $Si = 3.52 \text{ g mL}^{-1}$ ; Electronegativity B = 2.0; Al = 1.8]
  - (iii) Both boron and silicon show allotropy.
- (iv) Both boron and silicon do not form cations as their ionisation energy is very high.
- (v) Most of the compounds of boron and silicon are covalent.
- (vi) Boron and silicon burn in air on heating forming stable oxides B<sub>2</sub>O<sub>3</sub> and SiO<sub>2</sub> respectively. The oxides are acidic and combine with alkalies forming borates and silicates respectively.

$$\begin{array}{ccc} & B_2O_3 + 2NaOH \longrightarrow 2NaBO_2 + H_2O \\ or & B_2O_3 + 6NaOH \longrightarrow 2Na_3BO_3 + 3H_2O \\ & SiO_2 + 2NaOH \longrightarrow Na_2SiO_3 + H_2O \end{array}$$

(vii) Both boron and silicon combine with metals to form borides and silicides respectively.

It dissolves in HCl and H<sub>2</sub>SO<sub>4</sub> (dil.) evolving hydrogen.

$$2Al + 3H_2SO_4 \longrightarrow Al_2(SO_4)_3 + 3H_2$$

It becomes passive with conc. HNO<sub>3</sub>. A thin layer of Al<sub>2</sub>O<sub>3</sub> is formed on the surface which makes the metal inert.

Aluminates are less stable.

AlCl<sub>3</sub> is a solid.

It forms alloys with metals.

Al(OH)3 is amphoteric in nature.

Aluminium has a maximum covalency of six which is shown in compounds like Na<sub>3</sub>[AlF<sub>6</sub>]. This is due to the involvement of *d*-orbitals of the valency shell.

It does not form any stable and definite hydride. A polymeric hydride (AlH<sub>3</sub>)<sub>x</sub> has been reported.

Aluminium trihalides like AlCl<sub>3</sub>, AlBr<sub>3</sub> exist as dimers both in vapour state and in non-polar solvents as shown below.

It forms both covalent and electrovalent compounds.

It forms an ionic carbide, Al<sub>4</sub>C<sub>3</sub>, which on hydrolysis evolves CH<sub>4</sub>.

$$2B + 3Mg \longrightarrow Mg_3B_2$$
  
Si +  $2Mg \longrightarrow Mg_2Si$ 

(viii) Both do not directly combine with hydrogen. However, both form a number of hydrides. Hydrides are formed by almost identical manner. All are covalent hydrides.

$$Mg_3B_2 \xrightarrow{Dil.HCl}$$
 a mixture of boron hydrides  $Mg_2Si \xrightarrow{Dil.HCl}$  a mixture of silicon hydrides  $4BCl_3 + 3LiAlH_4 \longrightarrow 3LiCl + 3AlCl_3 + 2B_2H_6$   $SiCl_4 + LiAlH_4 \longrightarrow LiCl + AlCl_3 + SiH_4$ 

[Note: Boron hydrides (boranes) are electron deficient while silicon hydrides (silanes) are saturated compounds.]

(ix) Orthoboric acid  $(H_3BO_3)$  and ortho silicic acid  $(H_4SiO_4)$  form esters when treated with alcohols in presence of  $H_2SO_4$ .

$$H_3BO_3 + 3C_2H_5OH \xrightarrow{H_2SO_4} (C_2H_5)_3BO_3 + 3H_2O$$
Triethyl borate

 $H_4SiO_4 + 4C_2H_5OH \xrightarrow{H_2SO_4} (C_2H_5)_4SiO_4 + 4H_2O$ 
Tetraethyl silicate

[Note: The vapours of triethyl borate burn with green edged flame. This is the qualitative test of borates.]

(x) Halides of boron and silicon are hydrolysed.

$$BCl_3 + 3H_2O \longrightarrow H_3BO_3 + 3HCl$$
  
 $SiCl_4 + 4H_2O \longrightarrow H_4SiO_4 + 4HCl$ 

Both form complex halides.

$$BF_3 + HF \longrightarrow H[BF_4]$$
  
 $SiF_4 + 2HF \longrightarrow H_2[SiF_6]$ 

(xi) Both react with fused alkalies and evolve hydrogen.

$$2B + 6NaOH \longrightarrow 2Na_3BO_3 + 3H_2 \uparrow$$
  
Si +  $2NaOH + H_2O \longrightarrow Na_2SiO_3 + 2H_2 \uparrow$ 

(xii) Both combine with carbon to form carbides B<sub>4</sub>C and SiC. These are very hard substances and are used for cutting and abrasing purposes.

### 8.5 BORON

**Occurrence:** Boron is not found free in nature. In the combined state, it is found as the salts of boric acid. The important minerals of boron are:

(i) Borax (Tincal) Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O—It is found in Tibet, Ceylon,

California and Kashmir.

(ii) Colemanite  $Ca_{2}B_{6}O_{11}\cdot 5H_{2}O \text{---It is found in Asia Minor}$ 

and America.
Panderinite Ca<sub>2</sub>B<sub>6</sub>O<sub>11</sub>·31

 $\begin{array}{ll} \text{Panderinite} & \text{Ca}_2B_6O_{11}\cdot 3H_2O \\ \text{(iii)} \ \, \text{Boracite} & 2Mg_3B_8O_{15}\cdot MgCl_2\text{—It is found in Stass-furt,} \end{array}$ 

Germany

(iv) Boronatro calcite CaB<sub>4</sub>O<sub>7</sub>·NaBO<sub>2</sub>·8H<sub>2</sub>O—It is found in Chile.

(v) Kernite (Rasorite) Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·4H<sub>2</sub>O—It is found in Mojave desert

in America.

(vi) Boric acid H<sub>2</sub>BO<sub>3</sub>—It

id H<sub>3</sub>BO<sub>3</sub>—It occurs in the jets of steam called

soffioni escaping from ground in the volcanic

regions of Tuscany.

Boron is also present to some extent in plants and sometimes in coal ash.

**Extraction:** Boron is extracted from borax and colemanite minerals. The extraction involves two steps:

- (i) Preparation of boric anhydride, B<sub>2</sub>O<sub>3</sub>, from one of the minerals.
- (ii) Reduction of B<sub>2</sub>O<sub>3</sub>, to an impure brown, amorphous form of boron.

### 3 1st Step

(a) Preparation of B<sub>2</sub>O<sub>3</sub> from borax: The finely ground borax is heated with concentrated hydrochloric acid or concentrated sulphuric acid when sparingly soluble orthoboric acid, H<sub>3</sub>BO<sub>3</sub> separates out.

$$\begin{array}{c} Na_2B_4O_7 + 2HCl & \longrightarrow 2NaCl \ + \ H_2B_4O_7 \\ Borax & Tetraboric \ acid \\ Na_2B_4O_7 + H_2SO_4 - \longrightarrow Na_2SO_4 + H_2B_4O_7 \\ H_2B_4O_7 + 5H_2O & \longrightarrow 4H_3BO_3 \\ Orthoboric \ acid \\ \end{array}$$

Orthoboric acid is strongly heated to get  $B_2O_3$ .  $2H_3BO_3 \longrightarrow B_2O_3 + 3H_2O$ 

### (b) Preparation of B<sub>2</sub>O<sub>3</sub> from colemanite:

(i) The powdered mineral is fused with sodium carbonate.

$$\begin{array}{c} Ca_2B_6O_{11} + 2Na_2CO_3 \longrightarrow 2CaCO_3 + Na_2B_4O_7 + 2NaBO_2 \\ \text{Colemanite} & \text{Borax} & \text{Sodium} \\ \text{metaborate} \end{array}$$

The fused mass is extracted with hot water. CaCO<sub>3</sub> remains as insoluble. The filtrate containing borax and sodium metaborate is put to crystallisation when borax is obtained. The remaining solution is treated with carbon dioxide which converts sodium metaborate into borax.

$$4NaBO_2 + CO_2 \longrightarrow Na_2B_4O_7 + Na_2CO_3$$

The borax is then converted into B<sub>2</sub>O<sub>3</sub> in the manner described above.

(ii) The other method of conversion of colemanite into  $B_2O_3$  involves the suspension of mineral in water and passing of sulphur dioxide gas into the suspension.

$$Ca_2B_6O_{11} + 4SO_2 + 4H_2O \longrightarrow 2Ca(HSO_3)_2 + H_4B_6O_{11} + 7H_2O \longrightarrow 6H_3BO_3$$

$$Ca_2B_6O_{11} + 11H_2O + 4SO_2 \longrightarrow 2Ca(HSO_3)_2 + 6H_3BO_3$$

On concentration and cooling, crystals of boric acid separate out. These crystals form  $B_2O_3$  on strong heating.

$$2H_3BO_3 \longrightarrow B_2O_3 + 3H_2O$$

### 3 2nd Step

**Reduction of B\_2O\_3:** The reduction of boric anhydride  $(B_2O_3)$ , can be done with sodium, potassium or magnesium. The boric anhydride is mixed with sodium, potassium or magnesium powder and heated in a covered crucible.

$$\begin{array}{c} B_2O_3 + 6Na \longrightarrow 2B + 3Na_2O \\ B_2O_3 + 6K \longrightarrow 2B + 3K_2O \\ B_2O_3 + 3Mg \longrightarrow 2B + 3MgO \end{array}$$

The fused mass is stirred with iron rod as to oxidise the unreacted sodium or potassium. The mass is then boiled with dil. HCl when insoluble boron powder is obtained. It is washed with water and made dry. This is the amorphous variety of boron.

Amorphous boron of low purity is often known as Moissan boron. It is about 95–98% pure and impurities are chiefly metal borides. It is black in colour.

Modern method (Electrolytic method): Boron is obtained these days by the electrolysis of a fused mixture containing boric anhydride, magnesium oxide and magnesium fluoride at 1100°C. The electrolysis is done in carbon crucible which acts as anode and iron rod is used as cathode. The magnesium discharged at cathode reduces B<sub>2</sub>O<sub>3</sub> to boron.

$$2MgO \longrightarrow 2Mg + O_2$$
  
 $B_2O_3 + 3Mg \longrightarrow 2B + 3MgO$ 

Boron thus obtained is heated electrically in vacuum at 1100°C when the impurities are volatilised off and pure boron is obtained.

Crystalline variety of boron is obtained by the reduction of  $B_2O_3$  with aluminium powder.

$$B_2O_3 + 2Al \longrightarrow 2B + Al_2O_3$$

Aluminium is removed by heating the fused mass with NaOH solution.

High purity crystalline boron can also obtained by doing reduction of boron tribromide with hydrogen on tungsten wire at 1200°C.

$$2BBr_3 + 3H_2 \xrightarrow{W \text{ wire}} 2B + 6HBr$$

### **Physical Properties**

Elemental boron exists in two allotropic forms, (a) grey black, nonmetallic, high-melting point crystalline solid and (b) a dark brown amorphous powder with a structure based on clusters of 12 atoms Fig. 8.2. Crystalline boron is black and chemically inert in nature. It is very hard in nature. Amorphous boron is chemically brown and active. It melts at 2300°C

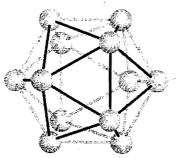

Fig. 8.2 The structure of boron is based on linked 12-atom units. The unit has 20 faces, so it is called an icosahedron

and boils at 2550°C. It is difficult to fuse it. It is bad conductor of heat and electricity. Its density is 2.4 g mL<sup>-1</sup>.

### **Chemical Properties**

(i) Reaction with air and oxygen: The element is very inert and is attacked by only the strongest oxidizing agents. Amorphous form when heated in air or oxygen at 700°C, burns with a reddish flame forming a mixture of oxide and nitride.

$$4B + 3O_2 \longrightarrow 2B_2O_3$$
  
 $2B + N_2 \longrightarrow 2BN$ 

(ii) Reaction with water: Boron is not affected by water under ordinary conditions, however, when steam is passed over red hot boron, hydrogen is liberated.

$$2B + 3H2O \longrightarrow B2O3 + 3H2\uparrow$$

(iii) Reaction with acids: Boron is not affected by nonoxidising acids. It is attacked by oxidising acids like conc.  $H_2SO_4$  and  $HNO_3$ .

B + 3HNO<sub>3</sub> 
$$\longrightarrow$$
 H<sub>3</sub>BO<sub>3</sub> + 3NO<sub>2</sub> $\uparrow$   
2B + 3H<sub>2</sub>SO<sub>4</sub>  $\longrightarrow$  2H<sub>3</sub>BO<sub>3</sub> + 3SO<sub>2</sub>  $\uparrow$ 

(iv) Reaction with alkalies: Boron dissolves in fused alkalies, liberating hydrogen.

$$2B + 6NaOH \longrightarrow 2Na_3BO_3 + 3H_2\uparrow$$

(v) Reaction with metals: Boron combines with strongly electropositive metals at high temperatures to form borides.

$$3Mg + B_2 \longrightarrow Mg_3B_2$$

(vi) Reaction with non-metals: Boron forms  $B_2S_3$  when heated with sulphur. It forms extremely hard substance boron

carbide  $(B_4C)$ , when heated with carbon in an electric furnace. Boron combines directly with chlorine and bromine at higher temperatures.

(vii) Reducing nature: It is a powerful reducing agent.

$$4B + 3CO_2 \longrightarrow 2B_2O_3 + 3C$$
  
 $4B + 3SiO_2 \longrightarrow 2B_2O_3 + 3Si$ 

#### Uses

Boron is used:

- (i) as a deoxidiser in the casting of copper.
- (ii) for making boron steels which are very hard and are used as control rods in atomic reactors.
  - (iii) as a catalytic agent.
- (iv) When boron fibres are incorporated in plastics, the result is a very tough material that is stiffer than steel yet lighter than aluminium and used in aircraft, missiles and body armour.
- (v) Boron steel or boron carbide rods are used to control the nuclear reactions. Boron has a very high cross-section to capture the neutrons. According to another concept boron absorbs neutron to make the boron having even number of neutrons.

$$_5B^{10} + _0n^1 \longrightarrow _5B^{11}$$

(vi) Boron is absolutely necessary as micronutrient for some green plants in trace amounts, but there is a relatively narrow concentration range above which boron is toxic to most plants. Boron production remains quite low despites the element's desirable properties of hardness and lightness.

### 8.6 COMPOUNDS OF BORON

### **■ 1. Boron Trioxide, B<sub>2</sub>O<sub>3</sub>**

It is also called sesquioxide. It is an anhydride of orthoboric acid.

It is prepared by burning boron in oxygen,

$$4B + 3O_2 \longrightarrow 2B_2O_3$$

or heating orthoboric acid to redness,

$$2H_3BO_3 \longrightarrow B_2O_3 + 3H_2O$$

### **Properties**

It is a white hygroscopic solid. It absorbs moisture (becoming opaque from transparent glassy mass) and finally converted into boric acid.

$$B_2O_3 + H_2O \longrightarrow 2HBO_2$$
 $Metaboric acid$ 
 $HBO_2 + H_2O \longrightarrow H_3BO_3$ 
Orthoboric acid

 $B_2O_3$  is, thus, the anhydride of orthoboric acid.

It is an acidic oxide. It combines with metal oxides when fused and forms metaborates. Some of the metaborates have characteristic colours (this is the basis of borax bead test).

$$CuO + B_2O_3 \longrightarrow Cu(BO_2)_2$$

[The volatile part of the salt is displaced by 
$$B_2O_3$$
.

 $CuO \cdot SO_3 + B_2O_3 \longrightarrow CuO \cdot B_2O_3 + SO_3$ 
 $(CuSO_4)$ 
 $Blue bead$ 
 $[Cu(BO_2)_2]$ 
 $Cr_2O_3 \cdot 3SO_3 + 3B_2O_3 \longrightarrow Cr_2O_3 \cdot 3B_2O_3 + 3SO_3]$ 
 $[Cr_2(SO_4)_3]$ 
 $Green bead$ 
 $[2Cr(BO_2)_3]$ 

It is reduced by magnesium.

$$B_2O_3 + 3Mg \xrightarrow{Heated} 2B + 3MgO$$

When reacted with strongly acidic oxides, it behaves as a base.

$$2B_2O_3 + P_4O_{10} \longrightarrow 4BPO_4$$

### Uses

Boron oxide, B<sub>2</sub>O<sub>3</sub> is used in glass industry with composition SiO<sub>2</sub>, B<sub>2</sub>O<sub>3</sub> and small amount of Al<sub>2</sub>O<sub>3</sub>, to lower the coefficient of thermal expansion. The coefficient of thermal expansion is appreciably lower in certain borosilicate glasses, in which many of the silicon sites are occupied by boron. "Pyrex" and "Kimex" are most familiar of these glasses, has a coefficient of linear expansion about one third that of ordinary soda-lime glass, Because borosilicate glasses do not expand much when heated, they survive rapid heating and cooling and so far is the material of choice for laboratory glassware and household ovenware.

### 2: Borax (Sodium Tetraborate) Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O

### **Preparation**

It is prepared by following methods:

- (i) Borax occurs naturally in dried up inland lakes of Tibet, Ceylon, California (U.S.A.) and India. In India, it is found in Laddakh and Puga valley of Kashmir. It is also called *Tincal* or *Suhaga*. Tincal contains about 45% of borax. Advantage is taken of its higher solubility in hot water (101 grams per 100 grams of water at 100°C) against low solubility at 0°C (1.3 grams per 100 grams of water at 0°C) in its purification. The natural tincal is dissolved in hot water and insoluble impurities are filtered off. The solution is concentrated and cooled when crystals of borax are obtained.
- (ii) Borax can be obtained from colemanite mineral (see section 8.5).
- (iii) From boric acid: Small quantities of borax are obtained from boric acid by neutralising it with soda ash.

$$4H_3BO_3 + Na_2CO_3 \longrightarrow Na_2B_4O_7 + 6H_2O + CO_2$$

### **Properties**

- (i) Borax is known in three forms:
- (a) **Prismatic borax**, which is the common form and is the decahydrate form, Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O. It is obtained by crystalli-

sing the solution at ordinary temperature. It is less soluble in cold water but highly soluble in hot water.

- (b) Octahedral form, which is the pentahydrate, Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·5H<sub>2</sub>O, is obtained by crystallising solution at 60°C. This is jeweller's borax.
- (c) **Borax glass** is the anhydrous form, Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>. It is obtained by heating the common form above its melting point. It is a colourless glassy mass and is not stable in moist air as it absorbs moisture and is gradually converted into decahydrate form.
- (ii) Basic nature: The solution of borax is alkaline in nature. This is due to its hydrolysis (salt of strong alkali and weak acid).

$$Na_2B_4O_7 + 7H_2O \Longrightarrow 2NaOH + 4H_3BO_3$$
  
Strong alkali Weak acid

(iii) Action of heat: On heating, borax first swells up due to elimination of water molecules. On further heating, it melts to a liquid which then solidifies to a transparent glassy mass.

$$\begin{array}{c} \text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O} \xrightarrow{\text{Heat}} \begin{array}{c} \text{Na}_2\text{B}_4\text{O}_7 \xrightarrow{740^{\circ}\text{C}} \\ \text{Anhydrous} \end{array} \xrightarrow{\text{Na}_2\text{B}_4\text{O}_7} \xrightarrow{\text{740}^{\circ}\text{C}} \\ \begin{array}{c} \text{2NaBO}_2 \\ \text{Sodium} \\ \text{metaborate} \end{array} \xrightarrow{\text{Boric}} \\ \begin{array}{c} \text{Boric} \\ \text{anhydride} \end{array}$$

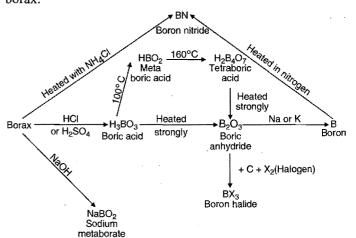

When hot glassy mass is brought in contact with a coloured salt and heated again in the flame, B<sub>2</sub>O<sub>3</sub> displaces the volatile oxides and combines with basic oxides to form metaborates. Metaborates of basic radicals have characteristic colours.

$$CuSO_4 + B_2O_3 \longrightarrow CuO \cdot B_2O_3 + SO_3$$

$$\downarrow \qquad \qquad Cu(BO_2)_2$$
Blue

This is the chemistry of borax bead test.

(iv) Various compounds of boron can be obtained from borax.

(v) Aqueous solution of borax acts as a buffer because it contains weak acid and its salt with strong base.

$$Na_2B_4O_7 + 7H_2O \longrightarrow 2Na[B(OH)_4] + 2H_3BO_3$$

**Structure of Borax:** Borax can be represented as  $Na_2[B_4O_5(OH)_4]\cdot 8H_2O$ . It has two tetrahedral and two triangular units joined together as shown in following figure.

#### Uses

Borax is used:

- (i) for the borax bead test in qualitative analysis.
- (ii) as a flux. (This is based on its property to dissolve many metal oxides to form borates of low melting points.)
  - (iii) as an antiseptic.
- (iv) in water softening as it forms insoluble calcium and magnesium borates (CaB<sub>4</sub>O<sub>7</sub>, MgB<sub>4</sub>O<sub>7</sub>).
- (v) in the manufacture of enamels and glazes for pottery and tiles.
- (vi) in making optical glasses and also borosilicate glass which is very resistant to heat and shock.
  - (vii) in leather industry for cleaning hides and skins.
  - (viii) for impregnating match-sticks to prevent after glow.
  - (ix) for glazing paper and playing cards.
  - (x) for stiffening of candles.

### 3. Orthoboric Acid, H<sub>3</sub>BO<sub>3</sub>

#### Preparation

(i) From borax: A hot concentrated solution of borax is treated with calculated quantity of concentrated sulphuric acid. When the solution is cooled, crystals of boric acid are obtained.

$$Na_2B_4O_7 + H_2SO_4 + 5H_2O \longrightarrow Na_2SO_4 + 4H_3BO_3$$

(ii) From colemanite: A large quantity of boric acid is made from colemanite mineral. The mineral is powdered and mixed with boiling water. Sulphur dioxide is circulated through the suspension when boric acid is formed.

 $Ca_2B_6O_{11} + 2SO_2 + 11H_2O \longrightarrow 2Ca(HSO_3)_2 + 6H_3BO_3$ On cooling, boric acid crystallises out.

(iii) From Tuscany soffioni: Boric acid occurs in the jets of steam called soffioni issuing from the ground in the volcanic regions of Tuscany. The jets are caught in large tanks of water. The resulting liquid is concentrated by steam. On allowing the hot solution to cool, crystals of boric acid separate out.

#### **Properties**

(i) It forms soft, white, needle like crystals having a soapy touch.

- (ii) It is less soluble in cold water but more soluble in hot water. It is steam volatile.
- (iii) It is a weak  $(K_a = 1 \times 10^{-9})$  monobasic acid. It does not act as a **proton-donor**, *i.e.*, protonic acid but behaves as a **Lewis acid.** It actually accepts a pair of electrons from OH<sup>-</sup> ion.

$$H \longrightarrow OH + B(OH)_3 \longrightarrow [B(OH)_4]^- + H^+$$

(iv) When heated at 100°C, it loses water and converted into metaboric acid.

$$H_3BO_3 \xrightarrow{100^{\circ}C} HBO_2 + H_2O$$

When metaboric acid is heated at 160°C, tetraboric acid results.

$$4HBO_2 \xrightarrow{160^{\circ}C} H_2B_4O_7 + H_2O$$

On strong heating, B<sub>2</sub>O<sub>3</sub> is formed,

$$H_2B_4O_7 \longrightarrow 2B_2O_3 + H_2O$$

(v) A mixture of ethyl alcohol with boric acid burns with green edged flame due to the formation of volatile ethyl borate.

$$H_3BO_3 + 3C_2H_5OH \longrightarrow B(OC_2H_5)_3 + 3H_2O$$
  
Ethyl borate

#### Uses

Orthoboric acid is used:

- (i) as an antiseptic and eye wash under the name 'boric lotion'.
  - (ii) in the manufacture of enamels and glazes for pottery.
  - (iii) as food preservative.
  - (iv) in glass industry.

**Structure of Boric Acid:** The electronic configuration of boron atom is  $2s^22p^1$ . In the excited state one electron from 2s is promoted to 2p orbital. The three singly occupied orbitals undergo  $sp^2$  hybridisation giving three hybridised orbitals. These three hybridised orbitals overlap individually with p-orbital of  $O^-$  forming three B— $O^-$  bonds.

Trigonal planar structure of BO3 unit

In boric acid, planar  $BO_3^{3-}$  units are joined by hydrogen bonds to give a layered structure as shown in Fig. 8.1.

#### 4. Halides of boron

#### Preparation

Boron combines with halogens and forms the halides of type  $BX_3$ , (X = F, Cl, Br, I).

Except  $BF_3$ , other trihalides can be prepared by the treatment of halogens on a mixture of  $B_2O_3$  and carbon at high temperature.

$$B_2O_3 + 3C + 3X_2 \longrightarrow 2BX_3 + 3CO$$
  
 $(X_2 = Cl_2, Br_2, I_2)$ 

The most important is boron trifluoride, BF<sub>3</sub>, an industrial catalyst produced by the reaction between boric oxide, calcium fluoride, and sulphuric acid.

$$3CaF_2 + B_2O_3 + 3H_2SO_4 \xrightarrow{\Delta} 2BF_3 + 3CaSO_4 + 3H_2O$$
  
Boron trihalides are also obtained by direct combination of

boron and halogens under suitable conditions.

$$2B + 3X_2 \longrightarrow 2BX_3$$

### **Properties**

- (i) These are covalent in nature due to small size and high charge density on B<sup>3+</sup> ion.
- (ii) These are non-electrolytes, as in liquid state do not conduct electricity.
- (iii) The boiling points of halides are very low. The boiling points increase as the atomic number of halogen increases. BF<sub>3</sub> is a colourless gas, BCl<sub>3</sub> is a colourless fuming liquid (b.pt. = 13°C), BBr<sub>3</sub> is also a colourless fuming liquid (b.pt. = 90°C) while BI<sub>3</sub> is a white fusible solid (m.pt. 310°C).
- (iv) The trihalides are electron deficient compounds. The B atom has an incomplete octet in all its halides. Boron atom acquires six electrons on account of three B—X bonds, i.e., 2 electrons short of an octet. Thus, the boron atom in BX<sub>3</sub> molecule can accept two more electrons, i.e., an electron pair from the donor atoms like N, P, O, S, F, etc., in NH<sub>3</sub>, PH<sub>3</sub>, H<sub>2</sub>O, H<sub>2</sub>S, HF, F, etc., respectively to form addition compounds (donor-acceptor compounds).

$$\begin{array}{ccc} H_3N \mbox{:} & + & BF_3 & \longrightarrow [H_3N \to BF_3] \\ & \mbox{Donor} & \mbox{Acceptor} \\ (Lewis base) & (Lewis acid) \end{array}$$

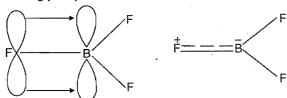

The relative Lewis acid character of boron trihalides is found to follow the following order,

$$BI_3 > BBr_3 > BCl_3 > BF_3$$

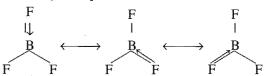

but the expected order on the basis of electronegativity of the halogens (electronegativity of halogens decreases from F to I) should be,

$$BF_3 > BCl_3 > BBr_3 > BI_3$$

This anomaly is explained on the basis of the relative tendency of the halogen atom to back donate its unutilised electrons to vacant p-orbital of boron atom. In BF<sub>3</sub>, boron has a vacant 2p-orbital and each fluorine has fully filled unutilised 2p-orbitals. Fluorine transfers two electrons to vacant 2p-orbital of boron, thus forming  $p\pi$ — $p\pi$  bond.

This type of bond has some double bond character and is known as dative or back bonding. All the three bond lengths are same. It is possible when double bond is delocalized. The delocalization may be represented as:

This bond reduces the electron deficiency of boron atom hence its Lewis acid character decreases. The tendency to form back bonding is maximum in  $BF_3$  and decreases from  $BF_3$  to  $BI_3$ . Thus,  $BCI_3$ ,  $BBr_3$  and  $BI_3$  are stronger Lewis acids than  $BF_3$ .

(v) All boron trihalides, except boron trifluoride, are hydrolysed to boric acid.

$$BCl_3 + 3H_2O \longrightarrow H_3BO_3 + 3HCl$$

The degree of hydrolysis increases from  $BCl_3$  to  $BI_3$ . Due to resistance of  $BF_3$  to hydrolysis and its tendency to act as Lewis acid,  $BF_3$  is used as a catalyst in organic reactions.

### 5. Hydrides of Boron or Boranes

Boron forms a number of hydrides. These are called boranes by analogy with alkanes. The boranes are an extensive series of highly reactive electron deficient binary compounds of boron and hydrogen, the boranes have three-centre bonds. These belong to one of the two series, viz.,  $B_nH_{n+4}$  and  $B_nH_{n+6}$ . The members of  $B_nH_{n+6}$  are less stable.

$B_nH_{n+4}$	$B_nH_{n+6}$
$B_2H_6$	$B_{4}H_{10}$
$B_5H_9$	$B_5H_{11}$
$B_6H_{10}$	$B_6H_{12}$
$B_{10}H_{14}$	$B_9H_{15}$

The simplest boron hydride,  $BH_3$ , is unknown. The most important hydride is diborane ( $B_2H_6$ ) which has been extensively studied.

### Diborane, B<sub>2</sub>H<sub>6</sub>

It is prepared:

(i) by the action of lithium aluminium hydride on boron trichloride in the presence of ether.

$$4BCl_3 + 3LiAlH_4 \xrightarrow{Ether} 2B_2H_6 + 3LiCl + 3AlCl_3$$

(ii) by passing silent electric discharge at low pressure through a mixture of boron trichloride or tribromide and excess of hydrogen.

$$2BCl_3 + 6H_2 \xrightarrow{\text{Silent electric}} B_2H_6 + 6HCl$$

(iii) by reacting lithium hydride with boron trifluoride.

$$8BF_3 + 6LiH \longrightarrow B_2H_6 + 6LiBF_4$$

#### **Properties**

(i) It is a colourless gas which is stable at low temperatures in the absence of moisture and grease. It bursts into flame in air. At higher temperatures, it changes to higher boranes and at red heat it decomposes to hydrogen and pure boron. It has disagreeable odour and causes headache.

$$B_2H_6 \xrightarrow{\text{Red heat}} 2B + 3H_2$$

 $B_2H_6 \xrightarrow{\text{Red heat}} 2B + 3H_2$ (ii) It burns in oxygen. The reaction is highly exothermic.

$$B_2H_6 + 3O_2 \longrightarrow B_2O_3 + 3H_2O + X$$

(iii) It readily reacts with water liberating hydrogen.

$$B_2H_6 + 6H_2O \longrightarrow 2H_3BO_3 + 6H_2$$

(iv) It reacts with strong alkalies to form metaborates and hydrogen.

$$B_2H_6 + 2KOH + 2H_2O \longrightarrow 2KBO_2 + 6H_2$$

(v) It reacts with chlorine forming boron trichloride.

$$B_2H_6 + 6Cl_2 \longrightarrow 2BCl_3 + 6HCl$$

(vi) In presence of anhydrous aluminium chloride, it reacts with dry HCl.

$$\begin{array}{c} B_2H_6 + HCl & \longrightarrow & B_2H_5Cl & + H_2 \\ & & \text{Chlorodiborane} \end{array}$$

(vii) Lithium borohydride is formed when diborane reacts with LiH in presence of ether.

$$2\text{LiH} + \text{B}_2\text{H}_6 \xrightarrow{\text{Ether}} 2\text{LiBH}_4$$

(viii) It reacts with carbon monoxide under pressure to form carbonyl, BH<sub>3</sub>CO.

$$B_2H_6 + 2CO \longrightarrow 2BH_3CO$$

(ix) It reacts with sodium amalgam forming an addition compound.

$$B_2H_6 + 2Na \text{ (amalgam)} \longrightarrow B_2H_6 \cdot Na_2$$

(x) At low temperatures, an addition product, B<sub>2</sub>H<sub>6</sub>·2NH<sub>3</sub>, is obtained with ammonia.

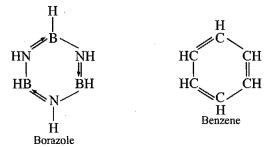

$$B_2H_6 + 2NH_3 \xrightarrow{\text{Low temp.}} B_2H_6 \cdot 2NH_3$$

When the addition product is heated at 200°C, a volatile compound borazole or inorganic benzene is formed.

$$3B_2H_6\cdot 2NH_3 \ \longrightarrow \ 2B_3N_3\cdot H_6 \ + \ 12H_2$$

Borazole

Borazole has a ring structure like benzene.

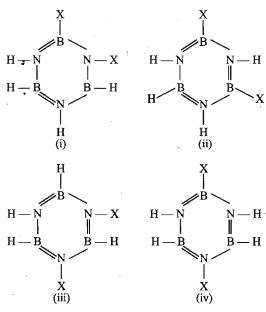

Note: (i) The addition product B<sub>2</sub>H<sub>6</sub>·2NH<sub>3</sub> is considered as an ionic product. It can be represented as [BH<sub>2</sub>(NH<sub>3</sub>)<sub>2</sub>]<sup>†</sup>[BH<sub>4</sub>].

When diborane with excess of NH3 mixture is heated at high temperature, boron nitride (BN)<sub>x</sub> is formed.

$$B_2H_6 + NH_3 \xrightarrow{Excess of NH_3} (BN)_x$$
high temp. Boron nitride

- (iii) The  $\pi$  bond in borazole (borazine) is formed by back bonding involving filled p-orbital of N and vacant orbital of B. However, borazole is more reactive than benzene.
- (iv) Disubstituted borazole, B<sub>3</sub>N<sub>3</sub>H<sub>4</sub>X<sub>2</sub> can have four isomers while benzene can have three.

#### Uses

The important uses of diborane are:

- (i) as a catalyst in polymerisation reactions.
- (ii) as a reducing agent in organic reactions.
- (iii) for making high energy fuels and propellants.
- (iv) for preparing hydrocarbons, alcohols, ketones and acids through hydroboration method.

Structure: Diborane is an example of electron deficient **compound.** Boron atom has three half filled orbitals in excited state, i.e., it can link with three hydrogen atoms. Thus, while each boron atom in diborane can link to itself three hydrogen atoms, there are no electrons left to form a bond between two boron atoms as shown below:

Dilthey in 1921 proposed a bridge structure for diborane. Four hydrogen atoms, two on the left and two on the right, known as terminal hydrogens and two boron atoms lie in the same plane. Two hydrogen atoms forming bridges, one above and other below, lie in a plane perpendicular to the rest of molecule. This structure shows that there are two types of hydrogen atoms—Terminal and bridging. 4-terminal hydrogen

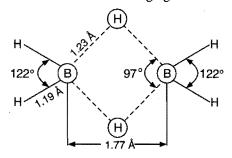

Fig. 8.3

atoms can easily be replaced by methyl groups but when two bridging hydrogen atoms are attacked, the molecule is ruptured.

According to molecular orbital theory, each of the two boron atoms is in  $sp^3$  hybrid state. Of the four hybrid orbitals, three have one electron each while the fourth is empty. Two of the four orbitals of each of the boron atom overlap with two terminal hydrogen atoms forming two normal B—H  $\sigma$ -bonds. One of the remaining hybrid orbital (either filled or empty) of one of the boron atoms, 1s-orbital of hydrogen atom (bridge atom) and one of hybrid orbitals of the other boron atom overlap to form a delocalised orbital covering the three nuclei with a pair of electrons. Such a bond is known as **three centre two electron bonds.** 

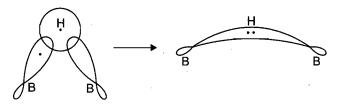

Fig. 8.4 Formation of three centre bond (B—H—B)

Similar overlapping occurs in one hydrogen atom (bridging) and fourth hybrid orbital of each boron atom. Thus, the formation of diborane molecule can be depicted as shown in the following figure:

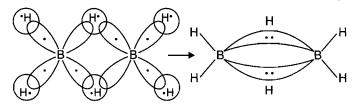

Fig. 8.5 Structure of diborane

On account of repulsion between the two hydrogen nuclei, the delocalised orbitals of bridges are drifted away from each other giving the shape of a banana. The three centre two electron bonds are also known as **banana bonds**.

#### 🍛 6. Boron Nitride, BN

#### **Preparation**

It is prepared:

(i) by heating boron in the atmosphere of nitrogen or ammonia.

$$2B + N_2 \longrightarrow 2BN$$
  
 $2B + 2NH_3 \longrightarrow 2BN + 3H_2$ 

(ii) by heating borax with ammonium chloride at red heat.

$$Na_2B_4O_7 + 2NH_4Cl \longrightarrow 2BN + 2NaCl + B_2O_3 + 4H_2O$$

The resulting mass is treated with dil. HCl, B<sub>2</sub>O<sub>3</sub> and NaCl dissolve and BN is left insoluble.

(iii) by heating B<sub>2</sub>O<sub>3</sub> with Hg(CN)<sub>2</sub>.

$$B_2O_3 + Hg(CN)_2 \longrightarrow 2BN + CO + CO_2 + Hg$$

(iv) Pure BN is obtained by the action of NH3 on BCl3.

$$\begin{array}{c} BCl_3 + 6NH_3 \longrightarrow B(NH_2)_3 + 3NH_4Cl \\ Boronamide \\ 2B(NH_2)_3 \xrightarrow{Heat} B_2(NH)_3 + 3NH_3 \\ Boronimide \end{array}$$

$$B_2(NH)_3 \longrightarrow 2BN + NH_3$$

Boron nitride is often prepared by chemical vapour deposition, a procedure used in the fabrication of several other ceramics as well. In this method, a controlled chemical reaction of gases on a contoured, heated surface gives a solid product of the desired shape. If a cup made of BN is needed a cup-shaped mold is heated to a temperature exceeding  $1000^{\circ}$ C, and a mixture of  $BCl_3(g)$  and  $NH_3(g)$  is passed over its surface the reaction,  $BCl_3(g) + NH_3(g) \longrightarrow BN(s) + 3HCl(g)$  deposits a cup-shaped layer of BN(s).

#### **Properties**

It is a white powder. It melts at very high temperature, 3000°C. It is insoluble in water. However, it gets decomposed when heated in steam under pressure to yield ammonia.

$$2BN + 3H_2O \longrightarrow B_2O_3 + 2NH_3$$

It is chemically inert compound. It remains unaffected by mineral acids. It dissolves in HF yielding ammonium borofluoride.

$$BN + 4HF \longrightarrow NH_4BF_4$$

It fails to react with alkalies. However, when fused with  $K_2CO_3$ , it yields potassium cyanate and potassium metaborate.

$$K_2CO_3 + BN \longrightarrow KCNO + KBO_2$$

**Structure:** The structure of boron nitride, BN, resembles to that of graphite (Fig. 9.3), consisting of flat planes of hexagons. In boron nitride, however, the hexagons consist of alternating B and N atoms in place of C atoms (Fig. 8.6).

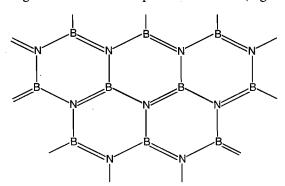

Fig. 8.6 The structure of boron nitride, BN

Recently, another crystalline form of boron nitride called **borazon** has been synthesised by application of high temperature and pressure. This form is even harder than diamond. It is used as abrasive.

Boron nitride cups and tubes are used to contain and evaporate molten metals. One form of boron nitride powder, BN, is composed of flat, platelike crystals that can easily slide over one another. It is used in cosmetics, where it gives a silky texture.

### 8.7 ALUMINIUM

**Occurrence:** Aluminium is a third most abundant element forming 8.3% of the earth's crust. It is a constituent of clay, slate and many types of silicate rocks. It is found only in the combined state. The important minerals are:

(i) Oxides: (a) Corundum (ruby, sapphire, emerald), Al<sub>2</sub>O<sub>3</sub>. (b) Diaspore, Al<sub>2</sub>O<sub>3</sub>·H<sub>2</sub>O. (c) Gibbsite, Al<sub>2</sub>O<sub>3</sub>·3H<sub>2</sub>O. (d) Bauxite, Al<sub>2</sub>O<sub>3</sub>·2H<sub>2</sub>O. It is the chief ore of aluminium from which extraction of aluminium is made. It is usually associated with varying amounts of ferric oxide and silica.

The pure aluminium oxide is colourless, but the presence of impurities can give various colours to it. Naturally occurring some impure forms of alumina, Al<sub>2</sub>O<sub>3</sub> are beautiful, rare and highly prized (a) Sapphire, alumina with Fe<sup>3+</sup> and Ti<sup>4+</sup> impurities (usually blue), (b) Ruby, alumina with Cr<sup>3+</sup> and (c) Topaz alumina with Fe<sup>3+</sup> impurities (usually red) are gem quality corundum.

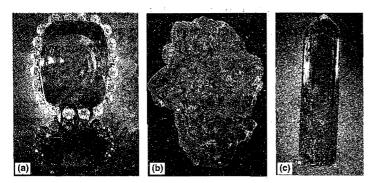

Fig. 8.7 Some of the impure forms of alumina (corundum) are prized as gems. (a) Sapphire is alumina with Fe<sup>3+</sup> and Ti<sup>4+</sup> impurities. (b) Ruby is alumina with Cr<sup>3+</sup> impurities.
 (c) Topaz is alumina with Fe<sup>3+</sup> impurities

- (ii) Fluoride: Cryolite, Na<sub>3</sub>AlF<sub>6</sub>. It is the second important ore of aluminium.
  - (iii) Basic sulphate: Alunite or alum stone,

$$K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 4Al(OH)_3$$
.

- (iv) Basic phosphate: Turquoise, AlPO<sub>4</sub>·Al(OH)<sub>3</sub>·H<sub>2</sub>O. It is usually blue coloured due to presence of copper phosphate.
- (v) Silicates: Feldspar, KAlSi<sub>3</sub>O<sub>8</sub>, kaolin, porcelain, mica, china clay, slate, etc., Al<sub>2</sub>O<sub>3</sub>·2SiO<sub>2</sub>·2H<sub>2</sub>O.

**Extraction:** Aluminium is mainly isolated from bauxite ore which is generally contaminated with ferric oxide and silica. The removal of ferric oxide and silica from bauxite ore is essential before it is subjected to electrolysis because it is rather difficult to remove iron and silicon from aluminium

metal, the presence of these elements makes the aluminium metal brittle and liable to corrosion. Thus, the extraction of aluminium from bauxite ore involves the following three steps.

- (i) Purification of bauxite ore, *i.e.*, removal of ferric oxide and silica.
  - (ii) Electrolytic reduction of Al<sub>2</sub>O<sub>3</sub>.
  - (iii) Electrolytic purification of aluminium.
- (i) Purification of bauxite ore: The following methods are used for purifying the bauxite ore.

### (A) Baeyer's Process

This process is mainly applied to bauxite ore containing ferric oxide as chief impurity. The colour of such ore is usually red and hence called red bauxite.

The powdered ore is first roasted at a low temperature as to convert any ferrous oxide, if present, into ferric oxide. It is then digested with a concentrated solution of sodium hydroxide (density 1.45 g mL<sup>-1</sup>) in an autoclave under pressure at 150°C for several hours. The aluminium oxide dissolves in caustic soda forming soluble sodium meta aluminate (NaAlO<sub>2</sub>) while ferric oxide and silica remain insoluble and settle down. These are removed by filtration.

$$Al_2O_3 \cdot 2H_2O + 2NaOH \longrightarrow 2NaAlO_2 + 3H_2O$$
Sodium metaaluminate

(soluble)

The sodium metaaluminate solution is agitated with freshly precipitated Al(OH)<sub>3</sub> for 36 hours when sodium metaaluminate undergoes hydrolysis with the formation of Al(OH)<sub>3</sub> precipitate.

$$NaAlO_2 + 2H_2O \longrightarrow NaOH + Al(OH)_3$$

The precipitate is washed and dried.

The solution of NaOH is concentrated and used again.

#### (B) Hall's Process

Bauxite is fused with sodium carbonate. Aluminium oxide,  $Al_2O_3$  combines with sodium carbonate forming sodium metaaluminate. The fused mass is extracted with water where  $Fe_2O_3$  and  $SiO_2$  remain as insoluble in the residue.

$$Al_2O_3 + Na_2CO_3 \longrightarrow 2NaAlO_2 + CO_2$$
Aluminium Sodium Sodium metaaluminate

The solution containing sodium metaaluminate is warmed to 50–60°C and carbon dioxide is circulated through it. Al(OH)<sub>3</sub> separates out as precipitate.

$$2NaAlO_2 + CO_2 + 3H_2O \longrightarrow 2Al(OH)_3 + Na_2CO_3$$

The precipitate is filtered, washed and dried.

The solution of Na<sub>2</sub>CO<sub>3</sub> is concentrated and used again.

### (C) Serpeck's Process

This process is used when silica is present in considerable amounts in bauxite ore. The ore is mixed with coke and heated

at 1800°C in presence of nitrogen, where AlN (aluminium nitride) is formed.

$$Al_2O_3 + 3C + N_2 \longrightarrow 2AlN + 3CO$$

Silica is reduced to silicon which volatilises off at this temperature.

$$SiO_2 + 2C \longrightarrow Si + 2CO$$

AlN is hydrolysed with water into aluminium hydroxide. This process has one distinct advantage that ammonia is obtained as a valuable by-product.

Calcination of aluminium hydroxide: The aluminium hydroxide precipitate obtained in the above process is calcined at 1500°C in a rotary kiln to obtain pure aluminium oxide, Al<sub>2</sub>O<sub>3</sub> (commercially reffered as *alumina*).

$$2Al(OH)_3 \xrightarrow{1500^{\circ}C} Al_2O_3 + 3H_2O$$

(ii) Electrolytic reduction of pure alumina: The electrolysis of pure alumina faces two difficulties: (i) Pure alumina is a bad conductor of electricity, (ii) The fusion temperature of pure alumina is about 2000°C and at this temperature when the electrolysis is carried of fused mass, the metal formed vaporises as the boiling point of aluminium is 1800°C.

The above difficulties are overcome by using a mixture containing alumina, cryolite (Na<sub>3</sub>AlF<sub>6</sub>) and fluorspar (CaF<sub>2</sub>) in the ratio of 20 : 40 : 20. The fusion temperature of this mixture is 900°C and it is a good conductor of electricity.

The electrolysis is carried out in an iron box lined inside with gas carbon which acts as cathode. The anode consists of carbon rods which remains dip in the fused mixture of the electrolyte from above. The fused electrolyte is covered with a layer of coke (Fig. 8.8).

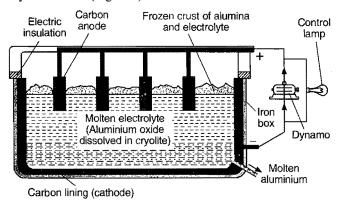

Fig. 8.8

The current passed through the cell serves two purposes—

- (i) Heating of the electrolyte—The temperature of the cell is automatically maintained at 900–950°C,
- (ii) Electrolysis—On passing current, aluminium is discharged at cathode. Aluminium being heavier than electrolyte sinks to the bottom and is tapped out periodically from tapping hole. Oxygen is liberated at anode. It attacks carbon rods forming CO and CO<sub>2</sub>. The process is continuous. When the

concentration of the electrolyte decreases, the resistance of the cell increases. This is indicated by the glowing of a lamp placed in parallel. At this stage more of alumina is added.

The exact mechanism of the electrolysis is not yet known. Two concepts have been proposed.

**First concept:** AlF<sub>3</sub> from cryolite ionises as,

$$AlF_3 \iff Al^{3+} + 3F^{-}$$

Al<sup>3+</sup> ions are discharged at cathode and F<sup>-</sup> ions at anode.

$$Al^{3+} + 3e \longrightarrow Al$$
 (at cathode)  
 $2F^{-} \longrightarrow F_2 + 2e$  (at anode)

The liberated fluorine reacts with alumina to form  $AlF_3$  and  $O_2$ . The oxygen attacks the carbon anodes to form CO and  $CO_2$ .

$$Al_2O_3 + 3F_2 \longrightarrow 2AlF_3 + \frac{3}{2}O_2$$

$$2C + O_2 \longrightarrow 2CO$$

$$C + O_2 \longrightarrow CO_2$$

Anodes are replaced frequently.

Second concept: Alumina (Al<sub>2</sub>O<sub>3</sub>) ionises as,

$$Al_2O_3 \Longrightarrow Al^{3+} + AlO_3^{3+}$$
Cathode Anode
 $Al^{3+} + 3e \longrightarrow Al \text{ (at cathode)}$ 

At anode AlO<sub>3</sub> is oxidised.

$$4AlO_3^{3-} \longrightarrow 2Al_2O_3 + 3O_2 + 12e$$
 (at anode)

Thus, the overall chemical reaction taking place during electrolysis is,

$$2Al_2O_3 \longrightarrow 4Al + 3O_2$$

Aluminium of 99.8% purity is obtained from this process.

(iii) Refining of aluminium by Hoope's electrolytic method: Aluminium is further purified by Hoope's process. The electrolytic cell consists of an iron box lined inside with carbon. The cell consists of three layers which differ in specific gravities. The upper layer is of pure aluminium which acts as cathode. The middle layer consists of a mixture of the fluorides of Al, Ba and Na. The lowest layer consists of impure aluminium which acts as anode. The middle layer works as electrolyte.

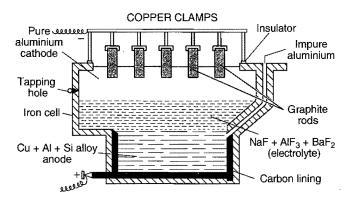

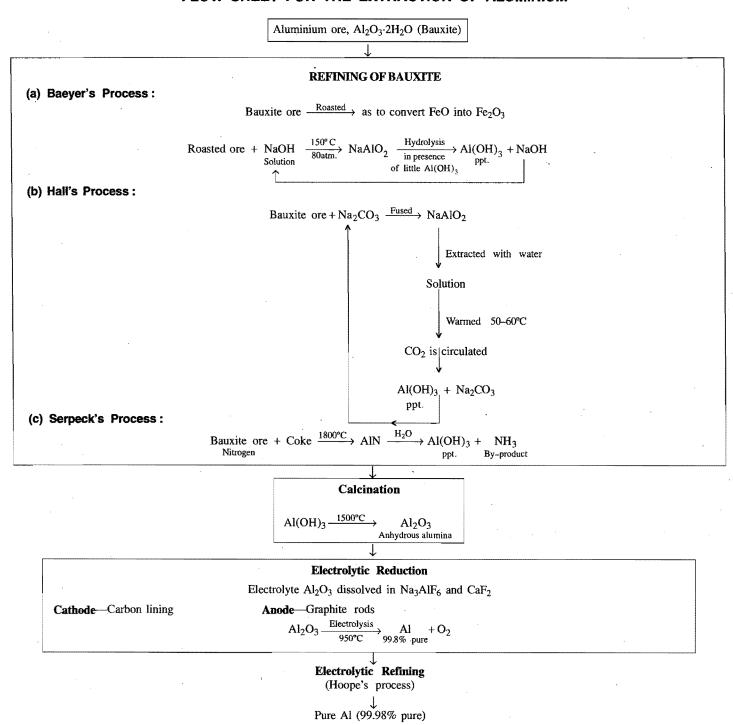

Fig. 8.9

The graphite rods dipped in pure aluminium and Cu-Al alloy rod at the bottom in the impure aluminium work as conductors. On electrolysis, aluminium is deposited at cathode from the middle layer and an equivalent amount of aluminium is taken up by the middle layer from the bottom layer (impure aluminium). Therefore, aluminium is transferred from bottom to the top layer through middle layer while the impurities are left behind. Aluminium thus obtained is 99.98% pure.

#### **Physical Properties**

(a) Aluminium is a bluish white lustre metal. The lustre is destroyed on long exposure to air due to formation of a thin film of oxide on the surface. (b) The density of aluminium is 2.7 g mL<sup>-1</sup> (light metal). It is malleable and ductile. (c) It is a good conductor of heat and electricity. (d) It melts at 660°C and boils at 1800°C. (e) It can be welded and cast but difficult to solder.

#### FLOW SHEET FOR THE EXTRACTION OF ALUMINIUM

### **Chemical Properties**

Aluminium is a chemically reactive metal although much less reactive than the alkali metals or alkaline earth metals.

(a) Action of air: Aluminium is not affected by dry air but in moist air a thin film of oxide is formed over its surface. Which protects the underlying metal from further reaction. It burns in oxygen producing brilliant light. The metal will burn vigorously once started however.

$$4A1 + 3O_2 \longrightarrow 2Al_2O_3$$

The reaction is highly exothermic and the heat evolved is used in the thermite process for the reduction of oxides of Cr, Fe, Mn, etc.

(b) Action of water: Pure aluminium is not affected by pure water. The impure aluminium is readily corroded by water containing salts (sea water). Aluminium decomposes boiling water evolving hydrogen.

$$2Al + 6H2O \longrightarrow 2Al(OH)3 + 3H2\uparrow$$

(c) Action of acids: The oxidation potential of aluminium is 1.66 volts. Thus, it is strongly electropositive, very reactive and a powerful reducing agent. It dissolves in HCl (dil. and conc.) and dilute sulphuric acid, evolving hydrogen.

$$2Al + 6HCl \longrightarrow 2AlCl_3 + 3H_2 \uparrow$$
  
 $2Al + 3H_2SO_4 \longrightarrow Al_2(SO_4)_3 + 3H_2 \uparrow$ 

The reaction with dil. H<sub>2</sub>SO<sub>4</sub> is very slow probably on account of the insolubility of the oxide film in this acid.

Hot concentrated sulphuric acid dissolves Al with evolution of SO<sub>2</sub>.

$$2AI + 6H2SO4 \longrightarrow AI2(SO4)3 + 3SO2 + 6H2O$$

Dilute and concentrated HNO<sub>3</sub> has no effect on Al, *i.e.*, Al is rendered passive by nitric acid. This is due to surface oxidation and formation of a thin film of oxide on its surface. Organic acids have little action on Al at ordinary temperatures.

(d) Action of alkalies: Aluminium is attacked by caustic alkalies with the evolution of hydrogen.

$$2Al + \underbrace{2NaOH + 2H_2O}_{Solution} \longrightarrow \underbrace{2NaAlO_2}_{Sodium meta-aluminate (soluble)} + 3H_2 \uparrow$$

$$2Al + 6NaOH \longrightarrow \underbrace{2Na_3AlO_3}_{Solution} + 3H_2 \uparrow$$

(e) Action of non-metals: Besides oxygen, aluminium reacts with non-metals directly to form corresponding compounds. Aluminium when heated in the atmosphere of

nitrogen, forms aluminium nitride.

$$2A1 + N_2 \longrightarrow 2AIN$$

Aluminium powder when fused with sulphur forms aluminium sulphide.

$$2A1 + 3S \longrightarrow Al_2S_3$$

Finely powdered heated aluminium combines with halogens to form corresponding halides.

$$2Al + 3X_2 \longrightarrow 2AlX_3$$
$$(X_2 = F_2, Cl_2, Br_2, I_2)$$

All these compounds are hydrolysed with water.

$$AlN + 3H_2O \longrightarrow Al(OH)_3 + NH_3$$
  
 $Al_2S_3 + 6H_2O \longrightarrow 2Al(OH)_3 + 3H_2S$   
 $AlX_3 + 3H_2O \longrightarrow Al(OH)_3 + 3HX$ 

(f) Reducing agent: It is a good reducing agent and reduces oxides of metals like Cr, Fe, Mn, etc.

$$Cr_2O_3 + 2AI \longrightarrow 2Cr + Al_2O_3 + heat$$
  
 $Fe_2O_3 + 2AI \longrightarrow 2Fe + Al_2O_3 + heat$   
 $3Mn_3O_4 + 8AI \longrightarrow 9Mn + 4Al_2O_3 + heat$ 

It reduces oxides of non-metals also.

$$3\text{CO}_2 + 4\text{Al} \longrightarrow 2\text{Al}_2\text{O}_3 + 3\text{C}$$
  
 $3\text{SiO}_2 + 4\text{Al} \longrightarrow 2\text{Al}_2\text{O}_3 + 3\text{Si}$ 

(g) Displacement of other metals: Being more electropositive it displaces copper, zinc and lead from the solutions of their salts.

$$3ZnSO_4 + 2Al \longrightarrow Al_2(SO_4)_3 + 3Zn$$
  
 $3CuSO_4 + 2Al \longrightarrow Al_2(SO_4)_3 + 3Cu$ 

#### **Uses**

- (i) Aluminium being cheap and light metal is largely used for making household utensils, trays, frames, etc. Bodies of automobiles, aircraft and roofing are made of aluminium sheet.
- (ii) Thin foils of Al are used in wrapping soaps, cigarettes and confectionary.
- (iii) Al wire is used in transmission lines and coils for dynamos and motors.
- (iv) It is used for making silvery paints for covering iron and other materials.
- (v) It is used in thermite process for the extraction of Cr, Mn, etc.
- (vi) Since it is not attacked by nitric acid, it is used in chemical plants and for transporting nitric acid.
- (vii) Because of its lightness, good conductivity and resistance to corrosion, it is used for making alloys which find applications in industries and arts. The important alloys of aluminium are:

Name of the alloy	Approximate composition	Uses
1. Magnalium	95% Al, 5% Mg	In the construction of airships, balances and pistons of motor engines.
2. Duralumin	95% Al, 4% Cu, 0.5% Mg, 0.5% Mn	Aeroplanes and automobile parts as its strength of toughness is comparable to mild
		steels.
3. Aluminium bronze	90% Cu, 9.5% Al, 0.5% Sn	For making utensils, cheap artificial jewellery, photo frames, coins, golden paints.
4. Nickeloy	95% Al, 4% Cu, 1% Ni	Aircraft parts.
5. Y-alloy	93% Al, 4% Cu, 2% Ni, 1% Mg	For making pistons and machinery parts.
6. Alnico	77% Steel; 2% Ni, 20% Al, 1% Co	For making permanent magnets.

- (viii) Aluminium amalgam is used as a reducing agent.
- (ix) Aluminium powder is used in fire works, flash light powder and in thermite welding.

## 8.8 COMPOUNDS OF ALUMINIUM

### 1. Aluminium Oxide or Alumina, Al<sub>2</sub>O<sub>3</sub>

It occurs in nature as colourless corundum and tinted with metallic oxides as ruby (red), sapphire (blue), amethyst (violet), emery (green), etc. These coloured oxides are precious stones. Hydrated oxide (Al<sub>2</sub>O<sub>3</sub>·2H<sub>2</sub>O) occurs as bauxite.

It is prepared by igniting aluminium hydroxide, aluminium sulphate or ammonium alum.

$$2Al(OH)_3 \longrightarrow Al_2O_3 + 3H_2O$$

$$Al_2(SO_4)_3 \longrightarrow Al_2O_3 + 3SO_3$$

$$(NH_4)_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O \longrightarrow$$

$$Al_2O_3 + 2NH_3 + 4SO_3 + 25H_2O$$

It is obtained in crystalline form by strongly heating a mixture of aluminium fluoride and boric oxide.

$$2AlF_3 + B_2O_3 \longrightarrow Al_2O_3 + 2BF_3$$

**Properties:** It is a white solid, insoluble in water. It is a stable and unreactive substance. It begins to volatilise at 1750°C and melts at 2050°C. It boils at 2250°C.

It shows amphoteric nature. When it is fused with oxides of chromium, iron and cobalt, synthetic semi-precious stones are obtained.

**Uses:** It is widely used for making bauxite bricks which are used for lining furnaces. Fused alumina is used as refractory material. When heated in an electric arc at 3000°C, a hard powder known as **alundun** is obtained which is used as abrasive. With lime, it is used as bauxite cement which is not affected by sea water. It is used in chromatography, in extraction of aluminium and in preparing precious stones.

### 2. Aluminium Chloride, AICl<sub>3</sub>

(i) Anhydrous aluminium chloride: It is prepared by passing dry HCl gas or chlorine gas over heated aluminium

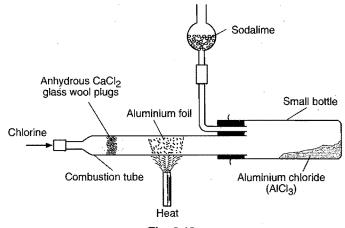

Fig. 8.10

turnings in absence of air. The vapours of aluminium chloride are condensed when solid anhydrous aluminium chloride is obtained.

$$2Al + 6HCl \longrightarrow 2AlCl_3 + 3H_2$$
  
 $2Al + 3Cl_2 \longrightarrow 2AlCl_3$ 

It can also be obtained by heating a mixture of alumina and carbon in an atmosphere of chlorine.

Al<sub>2</sub>O<sub>3</sub> + 3C + 3Cl<sub>2</sub> 
$$\xrightarrow{1000^{\circ}\text{C}}$$
 2AlCl<sub>3</sub> + 3CO

Vapours

↓ Cooled

Solid anhydrous
aluminium chloride

(ii) Hydrated aluminium chloride: AlCl<sub>3</sub>·6H<sub>2</sub>O, is formed when aluminium metal or aluminium hydroxide is dissolved in dilute hydrochloric acid.

$$2Al + 6HCl \longrightarrow 2AlCl_3 + 3H_2$$
  
 $Al(OH)_3 + 3HCl \longrightarrow AlCl_3 + 3H_2O$ 

HCl gas is circulated through the solution to obtain crystals of hydrated aluminium chloride.

#### **Properties**

(a) Anhydrous aluminium chloride is a white solid. It is deliquescent and fumes in air. On heating it sublimes at 180°C and the vapour density corresponds to the formula Al<sub>2</sub>Cl<sub>6</sub>. It is covalent when anhydrous as it does not conduct current in fused state. It is soluble in organic solvents such as alcohol, ether, benzene, etc. The dimeric formula is retained in nonpolar solvents but is broken into [Al(H<sub>2</sub>O)<sub>6</sub>]Cl<sub>3</sub> on dissolution in water on account of high heat of hydration. The molecule (dimer) is an autocomplex and is represented as,

(b) Anhydrous aluminium chloride fumes in moist air due to evolution of HCl.

$$Al_2Cl_6 + 6H_2O \longrightarrow 2Al(OH)_3 + 6HCl$$

When dissolved in water, it changes into hydrated aluminium chloride which is ionic in nature.

$$Al_2Cl_6 + 12H_2O \longrightarrow 2AlCl_3 \cdot 6H_2O$$
  
 $AlCl_3 \rightleftharpoons Al^{3+} + 3Cl^{-}$ 

(c) Anhydrous aluminium chloride forms an addition product with ammonia gas.

$$Al_2Cl_6 + 12NH_3 \longrightarrow 2[AlCl_3 \cdot 6NH_3]$$

(d) The solution of aluminium chloride in water is acidic in nature due to hydrolysis.

$$AlCl_3 + 3H_2O \longrightarrow Al(OH)_3 + 3HCl$$
Weak base Strong acid

(e) When ammonium hydroxide is added to the solution of aluminium chloride, a gelatinous precipitate of aluminium hydroxide appears which does not dissolve in excess of NH<sub>4</sub>OH.

$$AlCl_3 + 3NH_4OH \longrightarrow Al(OH)_3 + 3NH_4Cl$$

(f) When sodium hydroxide is added to the solution of aluminium chloride drop by drop, a white gelatinous precipitate appears which dissolves in excess of sodium hydroxide forming sodium meta-aluminate.

$$AlCl_3 + 3NaOH \longrightarrow Al(OH)_3 + 3NaCl$$
  
 $Al(OH)_3 + NaOH \longrightarrow NaAlO_2 + 2H_2O$ 

#### Uses

- (i) It is used as a catalyst in Friedel-Craft's reaction.
- (ii) It is also used in the manufacture of gasoline by cracking of high boiling fractions of petroleum.
- (iii) It finds extensive use in the manufacture of dyes, drugs and perfumes.

#### 3. Alums

Formerly, the term alum was used to describe only one double sulphate with 24 molecules of water of crystallisation, potassium aluminium sulphate,  $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$ , but now this term is used for all the double sulphates having the composition,

$$M_2SO_4 \cdot M_2'(SO_4)_3 \cdot 24H_2O$$

where M stands for monovalent basic radicals such as Na<sup>+</sup>, Kb<sup>+</sup>, Cs<sup>+</sup>, Ag<sup>+</sup>, Tl<sup>+</sup>, NH<sub>4</sub> and M' for trivalent basic radicals such as Al<sup>3+</sup>, Cr<sup>3+</sup>, Fe<sup>3+</sup>, Mn<sup>3+</sup>, Co<sup>3+</sup>, etc.

Some examples of alums are:

Potash alum	$K_2SO_4\cdot Al_2(SO_4)_3\cdot 24H_2O$
(commonly called alum)	
Ammonium alum	$(NH_4)_2SO_4\cdot Al_2(SO_4)_3\cdot 24H_2O$
Sodium alum	$Na_2SO_4\cdot Al_2(SO_4)_3\cdot 24H_2O$
Chrome alum	$K_2SO_4 \cdot Cr_2(SO_4)_3 \cdot 24H_2O$
Ferric alum	$(NH_4)_2SO_4\cdot Fe_2(SO_4)_3\cdot 24H_2O$

Alums are generally obtained when hot solutions of equimolar quantities of their constituent sulphates are mixed and the resulting solution is subjected to crystallisation.

Alums are crystalline compounds. In alums each metal ion is surrounded by six water molecules and the crystals of alums consist of  $[M(H_2O)_6]^+$ ,  $[M'(H_2O)_6]^{3+}$  and  $SO_4^{2-}$  ions. Alums are fairly soluble in hot water but less soluble in cold water. The solutions are acidic and have stringent taste. The solutions show the properties of ions of the constituent salts. The alums are isomorphous to each other and form mixed crystals.

Each alum has different melting point. Alums lose water of crystallisation when heated. If rapidly heated to a high temperature, the alum swells up and a porous mass called **burnt alum** is left behind.

### Potash Alum, K2SO4·Al2(SO4)3·24H2O

It is commonly known as alum.

#### Preparation

(i) From bauxite or aluminium sulphate: Bauxite is boiled with sulphuric acid to form aluminium sulphate. To this solution calculated quantity of  $K_2SO_4$  is added. The solution is concentrated and cooled. After some time crystals of potash alum are obtained.

$$\begin{array}{c} Al_2O_3 \,+\, 3H_2SO_4 \longrightarrow Al_2(SO_4)_3 \,+\, 3H_2O \\ Al_2(SO_4)_3 \,+\, K_2SO_4 \,+\, 24H_2O \longrightarrow K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O \\ & \quad \quad \text{Potash alum} \end{array}$$

(ii) From alum stone or alunite: Alum stone is treated with dilute sulphuric acid and the solution is boiled. A calculated quantity of  $K_2SO_4$  is added to the solution. The solution on cooling yields crystals of potash.

### **Properties**

- (a) It is a white crystalline compound.
- (b) It is soluble in water and its aqueous solution is acidic due to hydrolysis of  $Al_2(SO_4)_3$ .
- (c) On heating it swells up on account of elimination of water molecules.

$$\begin{array}{c} K_2 SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O \xrightarrow{200^{\circ}C} K_2 SO_4 \cdot Al_2(SO_4)_3 \, + \, 24H_2O \\ K_2 SO_4 \cdot Al_2(SO_4)_3 \xrightarrow{Red \ hot} K_2 SO_4 \, + \, Al_2O_3 \, + \, 3SO_3 \end{array}$$

(d) Its aqueous solution contains  $K^+$ ,  $Al^{3+}$  and  $SO_4^{2-}$  ions and their usual tests can be performed.

#### Uses

It is used:

- (i) as a mordant\* in dyeing and calico printing.
- (ii) in sizing of cheap quality of paper.
- (iii) in purification of water.
- (iv) as antiseptic and in stopping bleeding from cuts.
- (v) in leather tanning.

#### 4. Ultramarine

It is an artificial **Lapis-Lazuli**. Lapis-Lazuli is a rare mineral which has fine blue colour. It is a complex silicate of sodium

Kras 3 - Usa

The alums are effective in precipitating colloids, *i.e.*, act as coagulants. The alums have germicide properties. Alums are thus used in the purification of water, tanning of leather, as mordants in dyeing and as antiseptics.

<sup>\*</sup> A "mordant" is a compound that helps to attach the dye to the fabric.

and aluminium containing about 12 per cent of sulphur probably in the form of sodium sulphide.

It can be prepared artificially by heating a mixture of kaolin, soda ash, sulphur and charcoal to bright red heat. At first a white mass is formed which changes to a green mass in air. It is powdered and heated with more of sulphur where the blue variety having the composition Na<sub>5</sub>Al<sub>3</sub>Si<sub>3</sub>S<sub>3</sub>O<sub>12</sub> is obtained. Blue variety on heating in a current of dry chlorine changes to violet variety.

However, the blue variety is most common. It is used:

- (i) in making blue paint.
- (ii) in laundry for blueing purposes.
- (iii) in making wall paper and blue tinted paper.
- (iv) in calico-printing.

# 8.9 GOLDSCHMIDT'S ALUMINO-THERMIC PROCESS

Aluminium has the power of displacing elements less electropositive than itself from their oxides as it has great affinity for oxygen at high temperatures. The reaction being so strongly exothermic that the metal set free is obtained in the molten condition and it is protected from oxidation by a layer of fluid slag consisting of Al<sub>2</sub>O<sub>3</sub>.

Oxide + Al 
$$\longrightarrow \underbrace{Al_2O_3 + metal}_{Molton state}$$
 + heat energy

The reaction forms the basis of the alumino-thermic process. It was discovered by **Goldschmidt.** The process has two main applications:

(i) Extraction of metals and non-metals: The metals like Cr, Mo, Mn and non-metals like boron, silicon, etc., can be extracted from their corresponding oxides.

$$Cr_2O_3 + 2Al \longrightarrow 2Cr + Al_2O_3 + heat energy$$
  
 $3Mn_3O_4 + 8Al \longrightarrow 9Mn + 4Al_2O_3 + heat energy$   
 $B_2O_3 + 2Al \longrightarrow 2B + Al_2O_3 + heat energy$   
 $3SiO_2 + 4Al \longrightarrow 3Si + 2Al_2O_3 + heat energy$ 

The oxide is mixed with aluminium powder. The mixture is ignited in a fire clay crucible surrounded by sand with the help of a cartridge (containing magnesium powder and barium

peroxide). The large amount of heat generated in the reaction fuses both the alumina and the element set free. Two distinct layers are formed which are removed easily.

(ii) Thermite welding of metals: Another application is the welding of metals especially the welding of steel. The broken part to be welded is surrounded by a mould of sand and clay and heated to redness by means of a gasoline torch or a blast lamp. A mixture of aluminium powder and  $Fe_2O_3$  in the ratio of 1:3 (known as thermite) is taken in a crucible lined with magnesite and having a plug hole (Fig. 8.11). This is covered with a mixture of magnesium powder and barium peroxide with a magnesium ribbon inserted into it. The thermite is ignited with magnesium ribbon. Iron oxide is reduced to iron

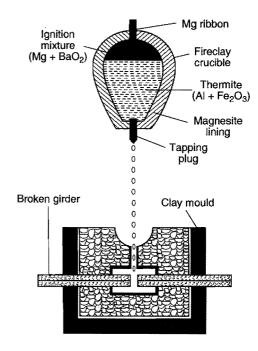

Fig. 8.11 Thermite welding

and temperature rises to about 2500°C. Molten iron thus produced is tapped into the parts to be welded. The heated surface of the broken iron melts and mingles with the molten iron, thus giving a perfect weld.

## SOME SOLVED PROBLEMS

**Example 1.** Starting from boric acid how would you prepare?

(a) Boric anhydride, (b) Boron trichloride, (c) Boron trifluoride, (d) Boron hydrides, (e) Ethyl borate, (f) Meta and tetraboric acids.

#### **Solution:**

(a) Boric acid on strong heating forms boric anhydride.  $2H_3BO_3 \xrightarrow{\text{Red hot}} B_2O_3 + 3H_2O$  (b) Boric acid is first converted into boric anhydride. It is now mixed with carbon and the mixture is heated in a current of chlorine when boron trichloride is formed.

$$B_2O_3 + 3C + 3Cl_2 \longrightarrow 2BCl_3 + 3CO$$

(c) It is prepared by heating boric acid with CaF<sub>2</sub> and concentrated sulphuric acid.

$$CaF_2 + H_2SO_4 \longrightarrow CaSO_4 + H_2F_2$$

$$2H_3BO_3 + 3H_2F_2 \longrightarrow 2BF_3 + 6H_2O$$

(d) Boric acid is first converted into boric anhydride. It is then heated with excess of magnesium powder in a covered crucible. The magnesium boride so formed is treated with dilute HCl when a mixture of boron hydrides is obtained.

$$H_3BO_3 \xrightarrow{\text{Red hot}} B_2O_3 \xrightarrow{\text{Mg}} Mg_3B_2 \xrightarrow{\text{Dil. HCl}}$$

A mixt. of boron hydrides

(e) Ethyl borate is formed when the mixture of boric acid and ethyl alcohol is warmed with concentrated sulphuric acid in the form of vapours.

$$3C_2H_5OH + H_3BO_3 \longrightarrow (C_2H_5)_3BO_3 + 3H_2O_3$$

(f) Orthoboric acid when heated at 100°C, decomposes into metaboric acid.

$$H_3BO_3 \xrightarrow{100^{\circ}C} HBO_2 + H_2O$$

When heated at 160°C, it decomposes into tetraboric acid.

or 
$$4H_3BO_3 \xrightarrow{160^{\circ}C} H_2B_4O_7 + 5H_2O$$
$$4HBO_2 \longrightarrow H_2B_4O_7 + H_2O$$

**Example 2.** Identify (A) and (B) in the following reactions:

Colemanite + (A) 
$$\longrightarrow Na_2B_4O_7$$
  
 $Na_2B_4O_7 + (B) \longrightarrow H_3BO_3$ 

#### **Solution:**

(A) is sodium carbonate.

$$Ca_2B_6O_{11} + 2Na_2CO_3 \longrightarrow Na_2B_4O_7 + 2NaBO_2 + 2CaCO_3$$

(B) is either concentrated H<sub>2</sub>SO<sub>4</sub> or HCl.

$$Na_2B_4O_7 + H_2SO_4 + 5H_2O \longrightarrow Na_2SO_4 + 4H_3BO_3$$
  
 $Na_2B_4O_7 + 2HCl + 5H_2O \longrightarrow 2NaCl + 4H_3BO_3$ 

**Example 3.** Explain the following with appropriate reason:

- (i) Although aluminium is above hydrogen in the electrochemical series, it is stable in air and water. [I.I.T. 1994]
- (ii) In the electrolytic manufacture of aluminium, carbon anodes are consumed.
- (iii) Cryolite is added to alumina in the electrolytic manufacture of aluminium.
  - (iv) Anhydrous AlCl<sub>3</sub> fumes in air.
  - (v) Alum is used in settling muddy water.

#### Solution:

- (i) The thin protective film of oxide, Al<sub>2</sub>O<sub>3</sub>, is formed which protects the metal from further attack of air and water and thus, it is stable in air and water.
- (ii) During electrolysis of cryolite and alumina in the manufacture of aluminium, oxygen is evolved at anode.

$$2F \longrightarrow F_2 + 2e$$
 (at anode);  $Al_2O_3 + 3F_2 \longrightarrow 2AlF_3 + \frac{3}{2}O_2$ 

Oxygen reacts with carbon anodes forming CO and CO<sub>2</sub>. Thus, carbon anodes are consumed.

- (iii) Pure alumina has very high fusion temperature and is bad conductor of electricity. To reduce its fusion temperature and to make it as good conductor of electricity, cryolite is added.
- (iv) Anhydrous aluminium chloride is hydrolysed in moist air and fumes of HCl are given out.

$$AlCl_3 + 3H_2O \longrightarrow Al(OH)_3 + 3HCl$$

(v) Alum acts as a germicide and strong coagulant. The muddy water consists colloidal particles of negative charge which are coagulated by Al<sup>3+</sup> ions given by alum. The coagulated mass then settles down.

**Example 4.** An inorganic Lewis acid (X) shows the following reactions:

- (i) It fumes in moist air.
- (ii) The intensity of fumes increases when a rod dipped in  $NH_4OH$  is brought near to it.
- (iii) An acidic solution of (X) on addition of  $NH_4Cl$  and  $NH_4OH$  gives a precipitate which dissolves in NaOH solution.
- (iv) An acidic solution of (X) does not give a precipitate with  $H_2S$ .

Identify (X) and give chemical reactions at steps (i) to (iii).

[Roorkee 1994]

#### Solution:

X is a Lewis acid and fumes in air, it may be anhydrous AlCl<sub>3</sub>.

(i) 
$$AlCl_3 + 3H_2O \longrightarrow Al(OH)_3 + 3HCl$$
  
Fumes

The fumes intensify as HCl and NH<sub>4</sub>OH react to form NH<sub>4</sub>Cl.

- (ii)  $NH_4OH + HCl \longrightarrow NH_4Cl + H_2O$
- (iii) Al(OH)<sub>3</sub> is precipitated on addition of NH<sub>4</sub>Cl and NH<sub>4</sub>OH.

This dissolves in NaOH forming sodium meta-aluminate—

$$AlCl3 + 3NH4OH \longrightarrow Al(OH)3 + 3NH4Cl$$

$$ppt.$$

$$Al(OH)3 + NaOH \longrightarrow NaAlO2 + 2H2O$$
Soluble

No precipitate is formed by passing H<sub>2</sub>S through solution.

**Example 5.** Explain the following:

- (i) Boron and aluminium halides behave as Lewis acids.
- (ii) Boron tribromide is stronger acid than boron trifluoride.
- (iii) Aluminium forms  $[AlF_6]^{3-}$  ion but boron does not form  $[BF_6]^{3-}$  ion.
  - (iv) Boron has high melting and boiling points.
- (v) The  $p\pi$ — $p\pi$  back bonding occurs in the halides of boron and not in those of aluminium.

#### **Solution:**

(i) Both boron and aluminium atoms in their halides  $(MX_3)$  possess six electrons in their valency shell. To complete octet,

they can accept a lone pair of electrons from a donor and thus act as Lewis acids.

- (ii) Back bonding occurs in boron halides to compensate the electron deficiency and hence Lewis acidity is decreased. The tendency of back bonding is maximum in BF<sub>3</sub> and decreases from BF<sub>3</sub> to BI<sub>3</sub> as the size of the halogen increases. *p*-orbitals of high energy shells in bromine overlap less effectively with vacant *p*-orbital of boron in BBr<sub>3</sub>. Thus, BBr<sub>3</sub> is stronger acid than BF<sub>3</sub> as it has still tendency to accept electrons to remove electron deficiency.
- (iii) Maximum coordination number of boron is four as it does not have d-orbitals while the maximum coordination number of aluminium is 6. Thus, Al forms  $[AlF_6]^{3-}$  ion while boron does not form  $[BF_6]^{3-}$  ion.
- (iv) Boron has giant covalent polymeric structure both in solid and liquid states and thus, it has high melting and boiling points.
- (v) The tendency to show  $p\pi p\pi$  back bonding depends on the size of central atom. This tendency decreases as the size of the central atom increases. Since aluminium has larger size than boron, the back bonding is not possible.

**Example 6.** (i) A white precipitate (B) is formed when a mineral (A) is boiled with  $Na_2CO_3$  solution.

- (ii) The precipitate is filtered and the filtrate contains two compounds (C) and (D). The compound (C) is removed by crystallisation and when  $CO_2$  is passed through the mother liquor left, (D) changes to (C).
- (iii) The compound (C) on strong heating gives two compounds (D) and (E).
- (iv) (E) on heating with cobalt oxide produces blue coloured substance (F).

Identify (A) to (F) and give chemical reactions for the reactions at steps (i) to (iv). [Roorkee 1995]

#### **Solution:**

(i) The mineral (A) is colemanite, Ca<sub>2</sub>B<sub>6</sub>O<sub>11</sub>·5H<sub>2</sub>O.

$$\begin{array}{c} \text{Ca}_2\text{B}_6\text{O}_{11} + 2\text{Na}_2\text{CO}_3(\textit{aq.}) \xrightarrow{\text{Boiled}} \\ (A) & 2\text{Ca}\text{CO}_3 + \underset{(B)}{\text{Na}_2\text{B}_4\text{O}_7} + 2\text{Na}\text{BO}_2 \\ & (B) & (C) & (D) \\ \hline \text{Insoluble} & \text{Soluble} \end{array}$$

(ii) (C), the borax is crystallised. The mother liquor consisting sodium metaborate is treated with  $CO_2$ .

$$4NaBO_2 + CO_2 \longrightarrow Na_2B_4O_7 + Na_2CO_3$$

$$(D) \qquad (C)$$

$$(iii) Na_2B_4O_7 \cdot 10H_2O \xrightarrow{\text{Heated}} Na_2B_4O_7 + 10H_2O$$

$$Anhydrous$$

$$Na_2B_4O_7 \xrightarrow{\text{Strongly}} 2NaBO_2 + B_2O_3$$

$$(D) \qquad (E)$$

$$(iv) CoO + B_2O_3 \xrightarrow{\text{Heat}} Co(BO_2)_2 \qquad 1$$

$$Cobalt metaborate$$

$$Blue coloured$$

So,  $A = \text{Ca}_2\text{B}_6\text{O}_{11}$ ·SH<sub>2</sub>O Colemanite and  $F = \text{Co}(\text{BO}_2)_2$ ;  $B = \text{Ca}_3$ ;  $C = \text{Na}_2\text{B}_4\text{O}_7$ ·10H<sub>2</sub>O;  $D = \text{Na}_3\text{BO}_2$ ;  $E = \text{B}_2\text{O}_3$ .

**Example 7.** Al $F_3$  is insoluble in anhydrous HF but dissolves on addition of NaF. Al $F_3$  precipitates out of the resulting solution when gaseous BF<sub>3</sub> is bubbled through. Give reasons.

#### **Solution:**

Anhydrous HF is a covalent compound and is strongly H-bonded. Therefore, it does not furnish  $F^-$  ions and  $AlF_3$  does not react to form  $\left[AlF_6\right]^{3-}$  and remains undissolved. When NaF is added,  $F^-$  ions are furnished as NaF is an ionic compound.  $AlF_3$  with  $F^-$  ions forms a complex ion, the sodium salt of which is soluble.

$$3NaF + AlF_3 \longrightarrow Na_3[AlF_6]$$
Soluble complex

B, being smaller in size and having higher electronegativity, has much higher tendency to form complexes than Al. Therefore, when BF<sub>3</sub> is added to the Al-complex, AlF<sub>3</sub> gets precipitated and B-complex comes into existence.

$$Na_3AlF_6 + 3BF_3 \longrightarrow 3Na[BF_4] + AlF_3$$

#### **Example 8.** Give reasons:

- (i) A mixture of NaOH and aluminium pieces is used to open the drain.
  - (ii) Aluminium utensils should not be kept in water overnight.
  - (iii) Aluminium wire is used in transmission cables.
  - (iv) Aluminium alloys are used to make aircraft body. **Solution:**
- (i) NaOH reacts with Al and evolves hydrogen. The pressure of the evolved hydrogen can be used to open the clogged drains.
- (ii) Aluminium is slowly attacked by water and dissolved oxygen to form  $Al_2O_3$  on the surface. A very small amount of  $Al_2O_3$  may dissolve to give  $Al^{3+}$  ions. Since,  $Al^{3+}$  ions are injurious to health, the drinking water is not kept in aluminium utensils for long.
- (iii) Al is a good conductor of electricity and also not affected by atmosphere. Hence, it is used in transmission cables.
- (iv) Al-alloys are light, tough and corrosion resistant. Hence, Al-alloys are used for making aircraft bodies.

**Example 9.** What is inorganic benzene? Why it is so called? How will you get it from diborane? [West Bengal, J.E.E. 2005]

#### Solution:

Borazine or borazole (B<sub>3</sub>N<sub>3</sub>H<sub>6</sub>) is known as inorganic benzene. It is so called because its structure is similar to that of benzene.

Like carbon in benzene, both B and N in borazine are  $sp^2$  hybridized. The  $\pi$ -bonding in borazine is dative, *i.e.*, a pair of electrons is donated by nitrogen to p-orbital of B.

At low temperature, borazine reacts with ammonia to form an addition compound.

$$B_2H_6 + 2NH_3 \longrightarrow B_2H_6 \cdot 2NH_3$$

When this compound is heated at 200°C, it decomposes to form borazine (volatile).

$$3B_2H_6 \cdot 2NH_3 \longrightarrow 2B_3N_3H_6 + 12H_2$$

**Example 10.** The first ionisation enthalpy of group 13 elements are:

Element	$\boldsymbol{B}$	Al	Ga	In	Tl
Ist I.E. $(kJ \ mol^{-1})$	801	577	579	558	589
How will you expla	in this	deviation.	from the	general	trend

#### Solution:

From B to Al, the ionisation enthalpy decreases as expected due to an increase in atomic size and screening effect. However, I.E. of Ga is only slightly higher than that of Al while that of thallium is much higher than those of Al, Ga and In. These deviations are explained as follows:

In periodic table, the position of Al, Ga, In and Tl in the respective periods is:

3rd period	Mg (s-block element)	Al
4th period	Zn (d-block element)	Ga
5th period	Cd (d-block element)	In
6th period	Hg (d-block element)	Tl

Thus, Al follows just after s-block elements while Ga and In follow after d-block elements and Tl after d- and f-block elements. The d-electrons in Ga and In and d- and f-electrons

in Tl do not shield the outer shell electrons very effectively. On account of this, the outer shell electrons are tightly held by the nucleus and hence higher energy is required for their removal. This explains why Ga has higher I.E. than Al. From Ga to In the shielding effect of additional 4d-electrons is slightly more than the effect of increased nuclear charge and hence, the I.E. of In is slightly less than Ga. In Tl, the shielding effect of d- and f-electrons is less than the effect of increased nuclear charge and hence, the I.E. is higher than In.

**Example 11.** Standard electrode potential values,  $E^o$  for  $Al^{3+}/Al$  is -1.66 V and that of  $Tl^{3+}/Tl$  is +1.26 V. Predict about the formation of  $M^{3+}$  ion in solution and compare the electropositive character of two metals.

#### **Solution:**

Standard electrode potential values suggest that aluminium has high tendency to make Al<sup>3+</sup> ions whereas Tl<sup>3+</sup> is unstable as it shows strong oxidising nature. Aluminium being able to form +3 ions easily, it is more electropositive than Tl.

**Example 12.** Account for the fact that aluminium chloride exists as a dimer,  $Al_2Cl_6$ .

#### Solution:

In AlCl<sub>3</sub>, Al is electron deficient (six electrons around Al) and chlorine atoms have lone pairs of electrons which can be donated. Al metal atoms complete their octet by forming a coordinate bond with chlorine atom of the other molecule, AlCl<sub>3</sub>. Thus, coordinate bond forming bridges by chlorine atoms between two Al atoms make a dimer molecule.

# SUMMARY AND IMPORTANT POINTS TO REMEMBER

- 1. Group IIIA or 13 of the periodic table consists of six elements-boron, aluminium, gallium, indium, thallium and ununtrium. These are p-block elements. The configuration of the outermost energy shell is  $ns^2np^1$ , i.e., this group marks the beginning of p-block.
- The members of group IIIA or 13 are less metallic in comparison to elements of IA (alkali metals) and IIA (alkaline earth metals) group.
  - Boron is regarded as a semi-metal. It is closer to non-metals than metals in its properties. Aluminium and rest of the elements are metallic in nature.
- 3. Aluminium is the most abundant metal and third most abundant element after oxygen and silicon by mass in the earth's crust. Boron is fairly rare but occurs as concentrated deposits of borax. Gallium is twice as abundant as boron but indium and thallium are much less common.
- 4. The atomic radii of members of group 13 are smaller than that of corresponding group IIA elements. The observed radius

- of Ga is nearly equal to that of Al. It is because the d electrons in Ga do not screen the nuclear charge effectively and the outer electrons experience more force of attraction and thereby causing decrease in its radius.
- 5. Density increases from boron to thallium. However, boron and aluminium have comparatively low values.
- 6. The melting points decrease from B to Ga and then increase from Ga to Tl. The high melting point of boron is due to the fact that it exists as a giant covalent polymer in both solid and liquid state. Gallium has an unusual structure. It consists of only Ga<sub>2</sub> molecules. Gallium melting point is 30°C and it exists as a liquid up to 2000°C and hence used in high temperature thermometry.
  - Al, In and Tl all have closed packed metal structures. However, boiling points follow a regular decrease from B to Tl.
- 7. Since p electrons are held less tightly than s electrons, the first ionisation energy of each element is rather low as compared to first ionisation energy of alkaline earth metal of

the same period. The second and third ionisation energies are considerably higher. The sum of three ionisation energies of these elements change in oscillating manner. B has maximum value. It decreases from B to Al, increases from Al to Ga, again decreases from Ga to In and then increases from In to Tl.

- Boron having very high ionisation energy is least electropositive, i.e., regarded as more non-metallic. Aluminium is most metallic or electropositive. The remaining three are weakly metallic in nature.
- B and Al exhibit an oxidation state of +3. Ga, In and Tl show +1 and +3 oxidation state due to inert pair effect.

Relative stability of +3 and +1 oxidation states can be given

B > Al > Ga > In > Tl + 3 stability decreases from B to Tl B < Al < Ga < In < Tl + 1 stability increases from B to Tl Tl<sup>3+</sup> ions show oxidising properties as these are converted into Tl<sup>+</sup> ions. Gallium appears to show +2 oxidation state in GaCl<sub>2</sub>. However, it is believed that this compound has structure Ga [GaCl<sub>4</sub>] which contains univalent and trivalent gallium ions.

- The bonding in the compounds of IIIA elements is mainly covalent due to following reasons:
  - (a) small size of ions and their high charge are responsible for high polarisation,
  - (b) the sum of three ionisation energies is very high,
  - (c) the electronegativity values are high,

Boron always shows covalency. Many simple compounds of other elements such as AlCl3 and GaCl3 are covalent when anhydrous. However, Al, Ga, In and Tl form metal ions in solutions as the hydration energies are very high.

Thallium compounds are ionic in nature.

- 11. Group IIIA elements form complexes much more readily than s-block elements because of their small size, increased charge and availability of vacant orbitals.
- Finely divided impure boron burns in air forming oxide while pure boron is less reactive.

Aluminium reacts with air forming its oxide which protects it from further action. The oxide film on Al is so useful that in industry it is purposely increased by an electrolytic process called anodising. Anodised cooking vessels are used as nonstick cookware. Ga and In are not affected in air. Tl forms an oxide on its surface.

- Boron is not affected by water or steam. Al decomposes cold water if the oxide layer is not present on its surface. Ga and In are attacked by water only in presence of oxygen. Tl is attacked by moist air.
- Boron is not affected by non-oxidising acids while other eléments dissolving forming trivalent salts. The oxidising acids attack all the elements. However, Al and

Ga become passive with conc. HNO<sub>3</sub>.

- 15. B, Al and Ga react with alkali solutions evolving H<sub>2</sub>. In and Tl are not affected.
- 16. All these elements combine with halogens forming corresponding halides.

Boron and aluminium combine with nitrogen and carbon on heating to form nitrides and carbides respectively.

The structure of boron nitride (BN) is similar to the structure of graphite. Recently, a crystalline form of boron nitride called borazon has been synthesised by application of high temperature and pressure. This form is even harder than diamond. It is used as abrasive. Boron carbide (B<sub>4</sub>C) is the hardest known artificial substance and is called norbide.

- 17. Boron combines with metals on heating to form borides. The rest of the elements do not combine with metals.
- All the members of group IIIA form oxides of the type  $M_2O_3$ . On moving down the group, there is gradual change from acidic to amphoteric and then to basic character.

Thallium also forms Tl<sub>2</sub>O which is more stable and behaves as alkali metal oxide.

**19.** All these elements form hydroxides of the type  $M(OH)_3$ . The basic nature of the hydroxides increases down the group. B(OH)<sub>3</sub>·(H<sub>3</sub>BO<sub>3</sub>) is acidic. B(OH)<sub>3</sub> coordinates with OH<sup>-</sup> group of water releasing proton.

$$B(OH)_3 + 2H_2O \longrightarrow [B(OH)_4]^- + H_3O^+$$

It reacts with NaOH to produce the sodium salt.

B(OH)<sub>3</sub> + NaOH 
$$\rightleftharpoons$$
 Na[B(OH)<sub>4</sub>]  $\frac{-2H_2O}{\sqrt{}}$  NaBO<sub>2</sub> (Sodium metaborate)

Boric acid contains triangular BO<sub>3</sub><sup>3-</sup> ion in which boron lies in sp<sup>2</sup> hybrid state. In solid state, B(OH)<sub>3</sub> units are hydrogen bonded to form two dimensional sheet.

Al(OH)<sub>3</sub> and Ga(OH)<sub>3</sub> are amphoteric as the tendency to rupture O-H bond decreases as the size of the ion increases. In(OH)<sub>3</sub> and Tl(OH)<sub>3</sub> are basic in nature.

- 20. The elements of group IIIA do not directly combine with hydrogen. However, a number of hydrides are known. Boron forms a number of stable covalent hydrides with a general formulae  $B_nH_{n+4}$  and  $B_nH_{n+6}$ . These are called boranes. Boranes are electron deficient compounds. The expected BH<sub>3</sub> is unknown. Aluminium forms a polymeric hydride,  $(AlH_3)_n$  known as alane. Gallium forms dimeric hydride, Ga<sub>2</sub>H<sub>6</sub> (digallane) and indium form a polymeric hydride. Thallium does not form any hydride.
  - B, Al and Ga form complex anionic hydrides such as NaBH<sub>4</sub>, LiAlH<sub>4</sub> and LiGaH<sub>4</sub>.
- 21. All the elements of group IIIA form trihalides. The boron halides are covalent. The boron halides act as Lewis acids. All boron halides except BF3 are hydrolysed to boric acid. BF3 forms an addition product with water as B-F bond is very strong.

$$BF_3 + H_2O \Longrightarrow H^+[BF_3OH]^- \xrightarrow{H_2O} H_3O^+[BF_3OH]^-$$

Boron halides for complex halides of the type  $H[BF_4]$ . The trifluorides of Al, Ga, In and Tl are ionic while the chlorides, bromides and iodides are largely covalent when anhydrous. However, their covalent nature decreases on moving from Ga to Tl. Trihalides fume in air and undergo hydrolysis. They also act as Lewis acids. However, this tendency decreases with increase in size of the cation. The form complex halides of the type  $[MX_6]^{3-}$ . They have the tendency to complete their octet by forming **dimers**. Dimer forms exist in vapour state and in non-polar solvents. Dimer structures disappear when dissolved in water. This is due to high hydration energy, when  $[M(H_2O)_6]^{3+}$  and  $3X^-$  ions are formed.

$$AlCl_3 + 9H_2O \longrightarrow [Al(H_2O)_6] (OH)_3 + 3H^+ + 3Cl^-$$

- 22. The important minerals of boron are:
  - (a) Borax, Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O,
  - (b) Colemanite, Ca<sub>2</sub>B<sub>6</sub>O<sub>11</sub>·5H<sub>2</sub>O,
  - (c) Boric acid, H<sub>3</sub>BO<sub>3</sub>.

Borax is also called **Tincal** or **Suhaga**. Tincal contains about 45% borax. Natural tincal is dissolved in hot water and insoluble impurities are filtered off. The solution is concentrated and cooled when crystals of borax are obtained. It exists in three forms (a) Prismatic borax—Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O (b) Octahedral—Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·5H<sub>2</sub>O. This is **Jeweller's borax**. It is obtained by crystallising solution at 60°C (c) Anhydrous—Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>. It is also called borax glass. It is not stable form as it absorbs moisture and gradually converted into decahydrate form. The solution of borax is alkaline in nature as it is a salt of a weak acid and strong alkali.

On heating if first swells up due to elimination of water and then melts which solidifies to transparent glassy bead.

$$\begin{array}{c} Na_{2}B_{4}O_{7}\cdot 10H_{2}O \xrightarrow{Heat} & Na_{2}B_{4}O_{7} \\ \hline & -10H_{2}O & Anhydrous \\ \hline & \hline & 2NaBO_{2} + B_{2}O_{3} \\ \hline & Glassy bead \end{array}$$

When the hot glassy bead is brought in contact with a coloured salt and heated again inflame, B<sub>2</sub>O<sub>3</sub> displaces volatile oxides to form metaborates. Metaborates exhibit characteristic colours. This is known as **borax bead test.** 

Colour of metaborates Blue Green Blue Green Brown

**23.** Boron is known to exist in two forms (a) amorphous and (b) crystalline.

Amorphous boron is obtained by reduction of B<sub>2</sub>O<sub>3</sub> with Na or K or Mg at high temperature in a covered crucible.

Crystalline form is obtained by the reduction of  $B_2O_3$  with Al—powder. Crystalline boron is black and chemically inert in nature. It is very hard. Amorphous boron is brown and chemically active. Boron is used as a deoxidiser in the casting of copper and for making boron steel which are used as control rods in nuclear reactors.

**24.** Diborane is the simplest hydride of boron. It is prepared by action of LiAlH<sub>4</sub> on boron trichloride in ether or by reacting lithium hydride with boron trifluoride. It is a colourless gas which is stable at room temperature. It has disagreeable odour and causes headache. It burns in air and reaction is highly exothermic. It is decomposed by water and alkalies liberating hydrogen. At low temperature, it forms an addition product with ammonia (B<sub>2</sub>H<sub>6</sub>·2NH<sub>3</sub>). When this product is heated at 200°C, a volatile compound, **borazole or inorganic** 

**benzene**  $(B_3N_3H_6)$  is formed which has structure similar to benzene.

In diborane molecule, four hydrogen atoms and two boron atoms lie in one plane. Above and below this plane, there are two bridging hydrogen atoms. Each boron atom forms four bonds though it has three electrons. Each bridge hydrogen atom is bonded to two boron atoms by sharing of two electrons. Such a covalent bond is called three centre electron pair bond or banana bond. Every boron atom is  $sp^3$ -hybridized. Diborane is used for making high energy fuels and propellants.

- **25.** On heating borazine, a product similar to naphthalene known as inorganic naphthalene is formed.
- **26.** The relative Lewis acid character of boron trihalides is found to follow the order:

$$BI_3 > BBr_3 > BCl_3 > BF_3$$

This is due to back donation by smaller halogen atoms to boron atom, *i.e.*, forming  $p\pi - p\pi$  bond. This tendency is maximum in fluorine and decreases from F to I as the size increases.

- 27. Aluminium is extracted from bauxite ore (Al<sub>2</sub>O<sub>3</sub>·2H<sub>2</sub>O). It is usually contaminated with ferric oxide and silica. The removal of these impurities is very essential before the pure alumina is put to electrolytic reduction. The removal is done by the application of the following processes.
  - (a) **Baeyer's process**—Applied when Fe<sub>2</sub>O<sub>3</sub> is the chief impurity. Conc. solution of NaOH used.
  - (b) Hall's process—Sodium carbonate is used.
  - (c) Serpeck's process—The ore is mixed with coke and nitrogen is passed at 1800°C.

AlN is formed which is hydrolysed into Al(OH)<sub>3</sub>. This method is applied when silica is present in abundance. Ammonia is obtained as a by-product.

The electrolysis of pure alumina presents two difficulties.

- (i) It is bad conductor of electricity.
- (ii) The melting point is about 2000°C.

These difficulties are overcome by using a mixture containing alumina, cryolite (Na<sub>3</sub>AlF<sub>6</sub>) and fluorspar (CaF<sub>2</sub>) in the ratio of 20: 40: 20. The fusion temperature of this mixture is 900°C and the mixture is good conductor of electricity. The electrolysis is carried out in an iron box lined by gas carbon which acts as cathode. The anode consists carbon rods. The overall chemical reaction is :  $2Al_2O_3 \longrightarrow 4Al + 3O_2$ 

Al of 99.8% purity is obtained. It is further purified by Hoope's electrolytic process.

- **28.** Because of its lightness, good conductivity and resistance to corrosion, it is used for making alloys. The important alloys are:
  - (a) Magnalium (95% Al + 5% Mg)
  - (b) Duralumin (95% Al + 4% Cu + 0.5% Mg + 0.5% Mn)
  - (c) Aluminium bronze (90% Cu + 9.5% Al + 0.5% Sn)
  - (d) Nickeloy (95%Al + 4% Cu + 1% Ni)
  - (e) γ-alloy (93% Al + 4% Cu + 2% Ni + 1% Mg)
  - (f) Alnico (77% Steel + 2% Ni + 20% Al + 1% Co)

Thin foils of Al are used for wrapping soaps, cigarettes and confectionery. Al wire is used in transmission lines and coils

for dynamos and motors. It is also used for making silvery paints and in thermite process.

29. Anhydrous AlCl<sub>3</sub> is prepared by passing dry HCl or Cl<sub>2</sub> gas over heated aluminium turnings in absence of air. It is also obtained by passing Cl<sub>2</sub> gas over heated mixture of Al<sub>2</sub>O<sub>3</sub> and coke. It is used as a catalyst in Friedel-Craft's reaction. The molecule is an autocomplex and is represented as:

Anhydrous AlCl<sub>3</sub> is a Lewis acid. Anhydrous form is covalent while hydrated form AlCl<sub>3</sub> 6H<sub>2</sub>O is ionic.

**30.** The term alum is used to describe any double sulphate having the composition  $M_2SO_4 \cdot M_2'(SO_4)_3 \cdot 24H_2O$ , where M stands for monovalent basic radical and M' for a trivalent basic radical.

The most commonly known alum is potash alum,  $K_2SO_4$ ·Al<sub>2</sub>( $SO_4$ )<sub>3</sub>·24H<sub>2</sub>O. It is used in purification of water, as an antiseptic and in stopping bleeding, as a mordant in dyeing and in leather tanning.

- Ultramarine is an artificial Lapis-Lazuli, a rare mineral (Na<sub>3</sub>Al<sub>3</sub>Sr<sub>3</sub>S<sub>3</sub>O<sub>12</sub>) which has fine blue colour. It is used in making blue paint.
- 32. Highly toxic element of group IIIA or 13 is thallium.
- 33. Precious stones such as sapphire, ruby, topaz, etc., are Al<sub>2</sub>O<sub>3</sub> containing oxides of other metals.
- 34. Double sulphates of divalent ions and trivalent ions with 24 water molecules of crystallisation are called **pseudoalums**, e.g., MSO<sub>4</sub>·M<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>·24H<sub>2</sub>O. These are not isomorphous with alums.
- **35.** Aluminium acetate is commonly known as **red liquor** which is used as a mordant in dyeing and calico printing.

### ■ Subjective Type Questions

#### 1. Answer the following:

- (a) Which element among group 13 elements has the highest ionisation enthalpy?
- (b) Which has higher ionisation enthalpy?

#### Al or Ga

- (c) Name the element of group 13 which forms the most stable compounds in +1 oxidation state.
- (d) Name the metal which is commonly used as a reducing agent in metallurgical operations.
- (e) Name the most abundant metal in the earth's crust. To which group does it belong?
- (i) By means of a balanced equation show how H<sub>3</sub>BO<sub>3</sub> behaves as an acid in water.
  - (ii) Anhydrous aluminium chloride is used as a catalyst. Explain.
  - (iii) Which elements of group 13 form amphoteric hydroxides.?
  - (iv) Why boron is unable to form  $[BF_6]^{3-}$  ion?
  - (v) Does Ga has +2 oxidation state in GaCl<sub>2</sub>?
- 3. (i) What are basic units in the structure of orthoboric acid? How are they linked?
  - (ii) What types of bonds are present in diborane?
  - (iii) What is the nature of boron halides?
  - (iv) Why boron halides do not exist as dimers? Why AlCl<sub>3</sub> exists as Al<sub>2</sub>Cl<sub>6</sub>?
  - (v) Explain briefly why boron trichloride is a gas and aluminium trichloride is a dimer solid.

#### 4. Give formula of the following:

- (a) (i) Panderinite
- (ii) Rasorite [M.L.N.R. 1996]
- (iii) Jeweller's borax
- (iv) Feldspar
- (v) Cryolite
- (vi) Corundum
- (vii) Alunite
- (viii) Turquoise
- (ix) Colemanite
- (x) Mica

(b) Write the formulae of the compounds, you would expect B and Al to form with halogens, oxygen, sulphur, nitrogen and carbon.

#### 5. Answer the following:

- (i) What is the outer electronic configuration of group IIIA elements?
- (ii) Name the first two elements of group IIIA.
- (iii) What is Tincal?
- (iv) What is thermite mixture?
- (v) What is inorganic benzene?
- (vi) Name the two metals present in common alum.
- (vii) Name the aluminium compound used in Friedel-Craft's reaction.
- (viii) What is silver paint?
- (ix) Name the metal which is commonly used as a reducing agent in metallurgical operations.
- (x) Name the compound of aluminium which is used as germicide and coagulant in the purification of water.

#### 6. What happens when?

- Dry chlorine gas is passed over hot mixture of alumina and coke.
- (ii) Borax is heated strongly.
- (iii) Excess of caustic soda is added to a solution of aluminium chloride.
- (iv) Water is added to aluminium nitride.
- (v) Water is added to aluminium carbide.
- (vi) Aluminium is heated with caustic soda solution.

[L.I.T. 1997]

- (vii) A mixture of borax and cobalt oxide is heated in flame.
- (viii) Alum is heated.
- (ix) Alum is added to copper sulphate solution.
- (x) Aluminium reacts with HNO<sub>3</sub>.
- 7. Starting from borax, how would you obtain?
  - (i) Boric acid, (ii) Boron trioxide, (iii) Boron,
  - (iv) Boron nitride, (v) Boron trichloride.

- 8. Starting from alumina, how would you obtain?
  - (i) Potash alum,
  - (ii) Anhydrous aluminium chloride,
  - (iii) Aluminium nitride, (iv) Sodium aluminate.
- 9. How you will obtain?
  - (i) Anhydrous aluminium chloride from potash alum.
  - (ii) Aluminium bromide from aluminium chloride.
  - (iii) Aluminium sulphate from potash alum.
  - (iv) Alum from aluminium.
- 10. Give an account for the following:
  - (a) No visible reaction occurs when aluminium is left in contact with concentrated nitric acid. [M.L.N.R. 1991]
  - (b) The hydroxides of aluminium and iron are insoluble in water. However, NaOH is used to separate one from the other. [I.I.T. 1991]
  - (c) Anhydrous aluminium chloride cannot be prepared by heating hydrated AlCl<sub>3</sub>·6H<sub>2</sub>O.
  - (d) Aluminium vessels should not be cleaned with cleansing agent containing washing soda.
  - (e) Duralumin is used in aircraft industry.
- 11. Explain the following with relevant reason.
  - (i) Aluminium vessels can be used to store concentrated nitric acid.

[**Hint**: HNO<sub>3</sub> forms a protective film, Al<sub>2</sub>O<sub>3</sub>, on the walls of the containers which is not acted upon by conc. HNO<sub>3</sub>.]

(ii) AlCl<sub>3</sub> forms a dimer but BCl<sub>3</sub> does not form dimer.

[Hint: AlCl<sub>3</sub> lacks back bonding as in BCl<sub>3</sub> because of increase in size of aluminium. Aluminium metal

atoms complete their octet by coordinate bond forming bridges by chlorine atoms between two Al atoms.]

(iii) Aluminium metal is frequently used as reducing agent for the extraction of metals such as Cr, Mn, Fe, etc.

[Hint: Al has great affinity for oxygen. Al, thus, removes oxygen from the oxides of less electropositive metals and acts as reducing agent.

$$Cr_2O_3 + 2Al \longrightarrow 2Cr + Al_2O_3$$
;  $\Delta H = -ve$ 

(iv) Aluminium cannot be prepared by the electrolysis of aqueous solution of its salt.

[Hint: Discharge potential of aluminium is higher than the discharge potential of hydrogen. Thus, the aqueous solution containing Al<sup>3+</sup> and H<sup>+</sup> ions, when electrolysed, the H<sup>+</sup> ions rather than Al<sup>3+</sup> ions are discharged at cathode and hydrogen is evolved.]

(v) The B—X distance is shorter than what is expected theoretically in B $X_3$  molecule (X = Cl, F, Br, I)?

[Hint: The bond B—X in BX<sub>3</sub> has double bond character due to back bonding. This brings resonance in the molecule which is responsible for shorter B—X distance than expected.

$$\dot{\bar{X}} = -\bar{\bar{B}} \stackrel{X}{\swarrow} \longleftrightarrow X - \bar{\bar{B}} \stackrel{\bar{\bar{X}}}{\swarrow} \longleftrightarrow X - \bar{\bar{B}} \stackrel{X}{\swarrow} ]$$

(vi) Although the ionisation potential of boron (8.30 eV) is less than gold (9.22 eV), yet former is a non-metal while the latter is a metal.

[Hint: This is due to structural difference in the solid states. In general, metals have large number of atoms as neighbours while non-metals have relatively less number of atoms as neighbours. Gold has 12 atoms as neighbours while boron has 6 or less atoms as neighbours in solid states.]

(vii) Why boron does not form B<sup>3+</sup> ion?

[Hint: The total sum of all the three ionisation energies of boron is so high that lattice energy liberated by interaction of B<sup>3+</sup> and anions is not enough for formation of this ion.]

(viii) Aluminium fluoride is ionic while AlCl<sub>3</sub> is covalent.

[Hint: The size of chloride ion is larger than fluoride ion. Due to higher polarisation in AlCl<sub>3</sub>, it behaves as a covalent compound. The electronegativity difference between Al and Cl is 1.5 while between Al and F it is 2.5. Thus, the bond between Al and F is ionic and between Al and Cl covalent in nature.]

(ix) First ionisation potential of Al is lower than that of Mg. [Hint: The electronic configuration of Al and Mg are 1s<sup>2</sup>, 2s<sup>2</sup> 2p<sup>6</sup>, 3s<sup>2</sup> 3p<sup>1</sup> and 1s<sup>2</sup>, 2s<sup>2</sup> 2p<sup>6</sup>, 3s<sup>2</sup> respectively. It is easier to remove electron from unpaired p-orbital than the paired s-orbital.]

(x) Borazine is more reactive than benzene.

[Hint: In benzene, C=C bonds are non-polar while in borazine, the bonds between boron and nitrogen are polar. Addition is frequent in borazine, the more negative group generally attaches to boron atoms.]

(xi) Certain metallic oxides are reduced with aluminium rather than with carbon during extraction.

[Hint: The metals which react with carbon to form carbides are extracted from their oxides by using aluminium as a reducing agent as it has high affinity for oxygen.]

[Hint: It dissolves in acid as well as in alkali.]

12. Write short notes on the following:

(xii) Al(OH)<sub>3</sub> is amphoteric.

- (i) Goldschmidt alumino-thermic process.
- (ii) Ultramarines.
- (iii) Alums.
- (iv) Electrolytic refining of aluminium metal.
- (v) Relative strength of boron halides as Lewis acids.
- (vi) Borax bead test.
- **13.** Describe the preparation, properties and uses of following compounds:
  - (i) Borax. (ii) Potash alum.
  - (iii) Anhydrous aluminium chloride.
  - (iv) Boric acid. (v) Borazine.
- **14.** Compare the properties of boron and aluminium under the following heads:
  - (i) Electronic configuration.
- (ii) Nature of oxides.

[M.L.N.R. 1994]

- (iii) Nature of chlorides.(v) Nature of hydrides.
- (iv) Action of acids.(vi) Nature of nitrides.
- 15. A certain salt (X) gives the following tests:
  - (i) Its aqueous solution is alkaline to litmus.

- (ii) On strongly heating it swells to give a glassy bead.
- (iii). When concentrated sulphuric acid is added to a hot concentrated solution of (X), white crystals of a weak acid separate out. Identify (X) and write down, the chemical equations for reactions at steps (i), (ii) and (iii).

[Roorkee 1992]

**[Hint:** (X) is borax, Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O

(i) 
$$Na_2B_4O_7 + 7H_2O \Longrightarrow 2NaOH + 4H_3BO_3$$
  
(Strong) (Weak)

Due to presence of NaOH, the aqueous solution is alkaline to litmus.

(ii) 
$$Na_2B_4O_7 \cdot 10H_2O \xrightarrow{\text{Heat} \text{ swells}} Na_2B_4O_7 + 10H_2O \xrightarrow{\text{Swells}} 2NaBO_2 + B_2O_3$$
Glassy bead

(iii) 
$$Na_2B_4O_7 + H_2SO_4 + 5H_2O \longrightarrow Na_2SO_4 + 4H_3BO_3$$

- **16.** A white crystalline compound (A) swells upon heating and gives violet coloured flame on bunsen flame. Its aqueous solution gives the following reactions.
  - (a) A white precipitate with BaCl<sub>2</sub> in presence of HCl.
  - (b) When treated with excess of NH<sub>4</sub>OH, it gives white gelatinous precipitate. The white precipitate dissolves in NaOH and reappears on boiling with concentrated solution of NH<sub>4</sub>Cl.
  - (c) It gives yellow precipitate with cobaltinitrite solution. Identify the compound (A) and explain the reactions.

**Hint:** The compound (A) is potash alum, K<sub>2</sub>SO<sub>4</sub>·Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>·24H<sub>2</sub>O. It swells upon heating due to evolution of water molecules.

$$K_2 SO_4 \cdot Al_2 (SO_4)_3 \cdot 24 H_2 O \xrightarrow{\text{Heating swells up}} K_2 SO_4 \cdot Al_2 (SO_4)_3 + 24 H_2 O$$

It gives violet colour to flame due to presence of potassium salt.

(a) The solution consists sulphate ions which combine with Ba<sup>2+</sup> ions to form white insoluble precipitate.

$$Ba^{2+} + SO_4^{2-} \longrightarrow BaSO_4$$

(b) With NH<sub>4</sub>OH, aluminium hydroxide is precipitated which dissolves in NaOH forming sodium meta-aluminate.

$$Al_2(SO_4)_3 + 6NH_4OH \longrightarrow 2Al(OH)_3 + 3(NH_4)_2SO_4$$

$$Al(OH)_3 + NaOH \longrightarrow NaAlO_2 + 2H_2O$$
Soluble

The solution on heating with ammonium chloride gives a precipitate of Al(OH)<sub>3</sub>.

$$NaAlO_2 + NH_4Cl + H_2O \longrightarrow Al(OH)_3 + NaCl + NH_3$$

(c) Potassium salt gives yellow precipitate with cobaltinitrite

$$2K_2SO_4 + Na_4[Co(NO_2)_6] \longrightarrow K_4[Co(NO_2)_6] + 2Na_2SO_4]$$
Yellow ppt.

- 17. An inorganic compound (A) shows the following reactions:
  - (i) It is white solid, exists as dimer and fumes in wet air.
  - (ii) It sublimes at 180°C and forms monomer if heated to 400°C.
  - (iii) Its aqueous solution turns blue litmus to red and gives a white precipitate with AgNO<sub>3</sub> solution which is soluble in NH<sub>4</sub>OH.

(iv) Addition of NH<sub>4</sub>OH and NaOH separately to the solution of (A) gives a gelatinous precipitate which is, however, soluble in excess of NaOH. Identify the compound (A).

[Ans. (A) is  $Al_2Cl_6$ ]

18. The metallic salt XY is soluble in water.

When the solution is treated with NaOH solution, a white precipitate (A) is formed. This precipitate is soluble in excess of NaOH solution to form a compound (B). When this solution is boiled with solid NH<sub>4</sub>Cl, a precipitate of a compound (C) is formed. An aqueous solution of XY upon treatment with BaCl<sub>2</sub> solution gave a white precipitate (D) which was insoluble in dilute HCl. The salt XY forms a double salt with potassium sulphate.

[Ans. 
$$XY = Al_2(SO_4)_3$$
; [A] = Al(OH)<sub>3</sub>; [B] = NaAlO<sub>2</sub>; [C] = Al(OH)<sub>3</sub>; [D] = BaSO<sub>4</sub>]

- **19.** Furnish the following information in connection with the extraction of aluminium by the electrolytic process:
  - (i) the composition of the electrolyte;
  - (ii) the reactions that take place at the electrodes;
  - (iii) the component of the electrolyte consumed;
  - (iv) collection of the extracted metal;
  - (v) the nature of the electrodes;
  - (vi) the temperature of electrolysis;
  - (vii) the role of different components of the electrolyte in the process of extraction.
- 20. Compound (X) on reduction with LiAlH<sub>4</sub> gives a hydride (Y) containing 21.72% hydrogen along with other products. The compound (Y) reacts with air explosively resulting in boron trioxide. Identify (X) and (Y). Give balanced reactions involved in the formation of (Y) and its reaction with air. Draw the structure of (Y). [I.I.T. 2001]

[Hint: 
$${}^{4}BCl_{3} + 3LiAlH_{4} \longrightarrow {}^{2}B_{2}H_{6} + 3AlCl_{3} + 3LiCl_{3}$$
  
% of hydrogen in  ${}^{6}B_{2}H_{6} = \frac{6}{27.62} \times 100 = 21.72$   
 ${}^{6}B_{2}H_{6} + 3O_{2} \xrightarrow{Explosion} {}^{2}B_{2}O_{3} + 3H_{2}O$ 

Structure of 
$$B_2H_6$$
  $H$   $H$   $H$   $H$   $H$   $H$ 

**21.** (a) How is boron obtained from borax? Give chemical equations with reaction conditions. Write the structure of B<sub>2</sub>H<sub>6</sub> and its reaction with HCl. [I.I.T. 2002]

[Hint: See the text.]

(b) Write balanced equations for reactions of  $BF_3$  and  $Al_4C_3$  with water. [I.I.T. 2002]

[Hint: 
$$4BF_3 + 6H_2O \longrightarrow H_3BO_3 + 3H_3^{\dagger}O + 3BF_4^{\dagger}$$
  
 $Al_4C_3 + 12H_2O \longrightarrow 4Al(OH)_3 + 3CH_4$ ]

### ■ Matching Type Questions

#### Match the following:

- [A] (a) Anhydrous AlCl<sub>3</sub>
  - (b) Alum
  - (c) Ultramarine

(b) Cryolite -

(c) Bauxite

(d) Borax

- (d) Borax
- (i) Antiseptic
- (ii) Alloy
- (iii) Friedel-Crafts reaction
- (iv) Complex blue coloured silicate
- (e) Magnelium (v) Tincal
- **B** (a) Colemanite (i) Na<sub>3</sub>AlF<sub>6</sub>
  - (ii) KAl(SO<sub>4</sub>)<sub>2</sub>·12H<sub>2</sub>O
    - (iii) Ca<sub>2</sub>B<sub>6</sub>O<sub>11</sub>·5H<sub>2</sub>O
    - (iv) Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O
  - (e) Potash alum (v) A1<sub>2</sub>O<sub>3</sub>·2H<sub>2</sub>O

- [C] (a) Inorganic benzene
- (i) Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O
- (b) Jeweller's borax (ii)  $B_2H_6$
- (c) Borax
- (iii) Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·5H<sub>2</sub>O
- (d) Diborane
- (iv) Mordant (v)  $B_3N_3H_6$
- (e) Alum
- (i) Building ships and
- (a) Good thermal conductivity
- aircrafts
- (b) Good electrical conductivity
- (ii) Utensils
- (c) Low density and resistance to corrosion
- (iii) Electric wires
- (d) Non-toxicity
- (iv) Adsorbent
- (e) Gel nature of Al(OH)<sub>3</sub> (v) Food packing

## tuswers

### Answers: Subjective Type Questions

1. (a) Boron

2.

- (b) Gallium
  - (c) Thallium
- (d) Aluminium (e) Aluminium, Group 13
- (i)  $B(OH)_3 + H \longrightarrow [B(OH)_4]^- + H^+$
- (ii) At atom in AlCl<sub>3</sub> has only 6 electrons in its valence shell. It needs two more electrons to complete its octet. It acts as a Lewis acid in reaction. It helps to generate electrophile  $R^+$  or RCO+, etc., which attacks benzene, i.e., the aromatic ring.
- (iii) Aluminium and gallium

$$Al(OH)_3 + 3HCl \longrightarrow AlCl_3 + 3H_2O$$

$$2Al(OH)_3 + 2NaOH + 6H_2O \longrightarrow 2NaAl(OH)_4 + 3H_2$$

$$Ga(OH)_3 + 3HCl \longrightarrow GaCl_3 + 3H_2O$$

$$2Ga(OH)_3 + 2NaOH + 6H_2O \longrightarrow 2NaGa(OH)_4 + 3H_2$$

- (iv) Boron cannot expand octet due to absence of d-orbitals in the valence shell.
- (v) GaCl<sub>2</sub> is actually Ga<sub>2</sub>Cl<sub>4</sub>, i.e., Ga<sup>+</sup>[Ga<sup>3+</sup>Cl<sub>4</sub>]. Ga has thus +1 and +3 oxidation states and not +2.
- (i) The basic units are BO<sub>3</sub><sup>3</sup> ions which are linked through hydrogen bonds. (ii) There are two types of bonds in diborane two electron normal
  - bonds and three centred two electron bonds.
  - (iii) Boron halides are electron deficient compounds. They act as Lewis acids.
  - (iv) Boron atom being small in size is unable to accommodate four large sized halogen atoms around it.
  - (v) In BCl<sub>3</sub>, boron attains an octet of electrons by means of  $p\pi$ - $p\pi$  bonding between B and Cl atoms. Thus, it exists as a monomeric gas. Due to large size of Al, efficient  $p\pi$ - $p\pi$  bonding cannot occur. Thus, AlCl<sub>3</sub> dimerises to attain an, octet by forming adative bond between Cl and Al atoms. Thus, it exists as a solid.
- (a)
  - (i)  $Ca_2B_6O_{11} \cdot 3H_2O_{11}$
- (ii) Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·4H<sub>2</sub>O,
- (iii) Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·5H<sub>2</sub>O<sub>7</sub>
- (iv) KAlSi<sub>3</sub>O<sub>8</sub>,
- (v) Na<sub>3</sub>AlF<sub>6</sub>,
- (vi) Al<sub>2</sub>O<sub>3</sub>,
- (vii)  $K_2SO_4$ · $Al_2(SO_4)_3$ · $4Al(OH)_3$ ,(viii)  $AlPO_4$ · $Al(OH)_3$ · $H_2O$ ,
- (ix)  $Ca_2B_6O_{11} \cdot 5H_2O$ ,
- (x)  $K_2O \cdot 3Al_2O_3 \cdot 6SiO_2 \cdot 2H_2O$ .
- (b) Formulae of the compounds of boron and aluminium: BX3 and AlX<sub>3</sub>, B<sub>2</sub>O<sub>3</sub> and Al<sub>2</sub>O<sub>3</sub>, B<sub>2</sub>S<sub>3</sub> and Al<sub>2</sub>S<sub>3</sub>, BN and AlN,  $B_{12}C_3$  and  $Al_4C_3$ .

- 5. (i)  $ns^2 np^1$ , (ii) Boron and aluminium, (iii) It is a mineral of boron. Its composition is Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub> 10H<sub>2</sub>O, (iv) Mixture containing 1 part Al powder and 3 parts Fe<sub>2</sub>O<sub>3</sub>, (v) Borazole or borazine, B<sub>3</sub>N<sub>3</sub>H<sub>6</sub> is known as inorganic benzene, (vi) Common alum is the double sulphate of potassium and aluminium. Its composition is, K<sub>2</sub>SO<sub>4</sub>·Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>·24H<sub>2</sub>O, (vii) Anhydrous aluminium chloride, AlCl<sub>3</sub>, (viii) Finely divided aluminium powder suspension in linseed oil, (ix) Aluminium, (x) Common alum, K<sub>2</sub>SO<sub>4</sub>·Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>·24H<sub>2</sub>O.
- $Al_2O_3 + 3C + 3Cl_2 \longrightarrow 2AlCl_3 + 3CO$ 
  - (ii)  $Na_2B_4O_7 \cdot 10H_2O \xrightarrow{-10H_2O} Na_2B_4O_7 \longrightarrow 2NaBO_2 + B_2O_3$
  - $AlCl_3 + 3NaOH \longrightarrow Al(OH)_3 + 3NaCl$ (iii)

$$Al(OH)_3 + NaOH \longrightarrow NaAlO_2 + 2H_2O$$

- $AIN + 3H_2O \longrightarrow Al(OH)_3 + NH_3$ (iv)
- $Al_4C_3 + 12H_2O \longrightarrow 4Al(OH)_3 + 3CH_4$ (v)
- (vi)  $2Al + 2NaOH + 2H_2O \longrightarrow 2NaAlO_2 + 3H_2$
- (vii)  $Na_2B_4O_7 \cdot 10H_2O \xrightarrow{-10H_2O} Na_2B_4O_7 \rightarrow 2NaBO_2 + B_2O_3$  $B_2O_3 + CoO \longrightarrow Co(BO_2)_2$ Cobalt metaborate
- (viii) It melts and loses water of crystallisation up to 200°C and white porous mass is obtained on red heat. This white mass is known as burnt alum.

$$\begin{array}{c} K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O \xrightarrow{200^{\circ}C} K_2SO_4 \cdot Al_2(SO_4)_3 + 24H_2O \\ K_2SO_4 \cdot Al_2(SO_4)_3 \xrightarrow{\text{Red heat}} K_2SO_4 + Al_2O_3 + 3SO_3 \end{array}$$

(ix) Being more electropositive, it displaces copper from copper sulphate.

$$3\text{CuSO}_4 + 2\text{Al} \longrightarrow \text{Al}_2 (\text{SO}_4)_3 + 3\text{Cu}$$

- (x) Nitric acid whether dilute or concentrated hardly affects aluminium at all. Aluminium is rendered passive. A thin film of Al<sub>2</sub>O<sub>3</sub> is formed on the surface of the metal.
- (i)  $Na_2B_4O_7 + H_2SO_4 + 5H_2O \longrightarrow 4H_3BO_3 + Na_2SO_4$ 
  - (ii)  $2H_3BO_3 \xrightarrow{Strongly} B_2O_3 + 3H_2O$
  - $B_2O_3 + 3Mg \longrightarrow 2B + 3MgO$
  - (iv)  $Na_2B_4O_7 + 2NH_4C1 \longrightarrow 2BN + B_2O_3 + 2NaCl + 4H_2O$
  - $B_2O_3 + 3C + 3Cl_2 \longrightarrow 2BCl_3 + 3CO$

8. (i)  $Al_2O_3 + 3H_2SO_4 \xrightarrow{Boiled} Al_2(SO_4)_3 + 3H_2O_4$ 

Calculated quantity of K2SO4 is added to above solution. The solution is cooled when crystals of alum are obtained.

 $Al_2(SO_4)_3 + K_2SO_4 + 24H_2O \longrightarrow K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$ 

- $Al_2O_3 + 3C + 3Cl_2 \xrightarrow{1000^{\circ}C} 2AlCl_3 + 3CO$
- $Al_2O_3 + 3C + N_2 \xrightarrow{1800^{\circ}C} 2AlN + 3CO$ (iii)
- $Al_2O_3 + 6NaOH \xrightarrow{Fused} 2Na_3AlO_3 + 3H_2O$ (iv)
- (i)  $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O + 6NH_4OH \longrightarrow$

$$K_2SO_4 + 3(NH_4)_2SO_4 + 2AI(OH)_3 + 24H_2O_{ppt}$$

$$2Al(OH)_3 \xrightarrow{\text{Heat}} Al_2O_3 + 3H_2O$$

$$Al_2O_3 + 3C + 3Cl_2 \xrightarrow{1000^{\circ}C} 2AlCl_3 + 3CO$$

 $AlCl_3 + 3NH_4OH \longrightarrow Al(OH)_3 + 3NH_4Cl$ 

$$Al(OH)_3 + 3HBr \longrightarrow AlBr_3 + 3H_2O$$
  
 $Al(OH)_3 \xrightarrow{Heat} Al_2O_3 + 3H_2O$ 

$$Al_2O_3 + 3C + 3Br_2 \longrightarrow 2AlBr_3 + 3CO$$

(iii) Potash alum + NH<sub>4</sub>OH → Al(OH)<sub>3</sub>

$$2Al(OH)_3 + 3H_2SO_4 \longrightarrow Al_2(SO_4)_3 + 6H_2O$$

(iv) Al 
$$\xrightarrow{\text{H}_2\text{SO}_4}$$
 Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>  $\xrightarrow{\text{K}_2\text{SO}_4 \text{ soln.}}$   $\xrightarrow{\text{Solution is}}$  K<sub>2</sub>SO<sub>4</sub>·Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>·24H<sub>2</sub>O  $\xrightarrow{\text{Solution is}}$ 

- 10. (a) Aluminium is rendered passive.
  - (b) Al(OH)<sub>3</sub> dissolves in NaOH while Fe(OH)<sub>3</sub> remains insoluble.

$$Al(OH)_3 + NaOH \longrightarrow NaAlO_2 + 2H_2O$$

(c) Hydrolysis of AlCl<sub>3</sub> occurs into Al<sub>2</sub>O<sub>3</sub>.

$$2AICl_3 + 3H_2O \longrightarrow Al_2O_3 + 6HCl_3$$

- (d) Aluminium dissolves in caustic alkalies.
- (e) Duralumin is an alloy of aluminium (95%), Cu (4%), Mg (0.5%) and Mn (0.5%). It is light and tough. It is resistant to corrosion.
- 19. (i) Pure Al<sub>2</sub>O<sub>3</sub> 20%; Cryolite Na<sub>3</sub>AlF<sub>6</sub> 60%; Fluorspar CaF<sub>2</sub>
  - (ii) Reactions at electrodes,

At cathode: 
$$Al^{3+} + 3e \longrightarrow Al$$

At anode:

$$2F^- \longrightarrow F_2 + 2e$$

$$2Al_2O_3 + 6F_2 \longrightarrow 4AlF_3 + 3O_2$$

- (iii) The component consumed during electrolysis, Al<sub>2</sub>O<sub>3</sub>.
- (iv) The liberated metal in the molten state is taken out through an outlet near the bottom of the electrolytic cell.
- (v) Carbon lining of the electrolytic cell acts as cathode and carbon rods act as anode.
- (vi) 950°C.
- (vii) Molten cryolite acts as the solvent for Al<sub>2</sub>O<sub>3</sub>. Fluorspar decreases the viscosity of the mixture. Both decrease the fusion temperature from 2050°C to 950°C and make the mass good conductor of electricity.

#### Answers: Matching Type Questions

- [A] (a—iii); (b—i); (c—iv); (d—v); (e—ii)
- [B] (a—iii); (b—i); (c—v); (d—iv); (e—ii)
- [C] (a-v); (b-iii); (c-i); (d-ii); (e-iv)
- [D] (a-ii); (b-iii); (c-i); (d-v); (e-iv)

## ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. Correct match is:
  - (a) Ordinary form of borax

Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·5H<sub>2</sub>O

- (b) Colemanite
- Ca<sub>2</sub>B<sub>6</sub>O<sub>11</sub>·5H<sub>2</sub>O
- (c) Boronatrocalcite
- 2Mg<sub>3</sub>B<sub>8</sub>O<sub>15</sub>·MgCl<sub>2</sub>
- (d) Octahedral form of borax:

Ans. (b)

- Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O
- 2. Which of the following is correct?
  - (a) The members of  $B_nH_{n+6}$  are less stable than  $B_nH_{n+4}$
  - (b) Diborane is coloured and unstable at room temperature
  - (c) The reaction of diborane with oxygen is endothermic
  - (d) All of the above

Ans. (a)

- 3. In which of the following, a salt of the type KMO2 is
  - (a)  $B_2H_6 + KOH(aq.) \longrightarrow$  (b)  $Al + KOH(aq.) \longrightarrow$
  - (c) Both

(d) None

Ans. (c)

[Hint: 
$$B_2H_6 + 2KOH + 2H_2O \longrightarrow 2KBO_2 + 6H_2$$
;  
 $2Al + 2KOH + 2H_2O \longrightarrow 2KAlO_2$  +  $3H_2$ ]
Pot. metaaluminate

- 4. Which of the following minerals does not contain aluminium?
  - (a) Cryolite
- (b) Mica
- (c) Feldspar
- (d) Fluorspar

Ans. (d)

[Hint: Cryolite—Na<sub>3</sub>AlF<sub>6</sub>; Feldspar—KAlSi<sub>3</sub>O<sub>8</sub>; Mica — K<sub>2</sub>O·3Al<sub>2</sub>O<sub>3</sub>·6SiO<sub>2</sub>·2H<sub>2</sub>O; Fluorspar—CaF<sub>2</sub>]

- The function of fluorspar in the electrolytic reduction of alumina dissolved in fused cryolite (Na<sub>3</sub>AlF<sub>6</sub>) is :
  - (a) as a catalyst
  - (b) to lower the temperature of melt and to make the fused mixture very conducting
  - (c) to decrease the rate of oxidation of carbon anode
  - (d) none of the above

Ans. (b)

- 6. A layer of coke is spread over bauxite during electrolytic reduction of alumina by Hall - Heroult process. This layer acts as a/an:
  - (a) flux
  - (b) slag to remove impurities
  - (c) reducing agent
  - (d) insulation and does not allow heat to escape
- Which of the following compounds is formed in borax bead test? [A.I.I.M.S. 2004]
  - (a) Metaborate
- (b) Tetraborate
- (c) Double oxide
- (d) Orthoborate

[Hint: Borax on heating gives B<sub>2</sub>O<sub>3</sub> (transparent glassy mass). When hot B<sub>2</sub>O<sub>3</sub> is brought in contact with a coloured salt, metaborates are formed.

$$Na_2B_4O_7 \cdot 10H_2O \xrightarrow{-Heat} B_2O_3 \xrightarrow{Coloured} Metaborate$$

$$CuSO_4 + B_2O_3 \longrightarrow Cu(BO_2)_2 + SO_3$$

- 8. Aluminium chloride exists as a dimer, Al<sub>2</sub>Cl<sub>6</sub>, in solid state as well as in solution of non-polar solvents such as benzene. When dissolved in water, it gives: [A.I.E.E. 2004]
  - (a)  $Al^{3+} + 3Cl^{-}$
- (b)  $[Al(H_2O)_6]^{3+} + 3Cl^{-}$
- (c)  $[Al(OH)_6]^{3-} + 3HCl$
- (d)  $Al_2O_3 + 6HCl$

Ans. (b)

[Hint: The dimeric formula, Al<sub>2</sub>Cl<sub>6</sub>, is retained in non-polar solvent but is broken into [Al(H<sub>2</sub>O)<sub>6</sub>]Cl<sub>3</sub> on dissolution in water on account of high heat of hydration.]

- 9. Inorganic graphite is:
  - (a)  $B_3N_3H_6$
- (b)  $B_3N_3$

(c) SiC

(d)  $P_4S_3$ 

Ans. (b)

- 10. Hydrated AlCl<sub>3</sub> is used as:
  - (a) catalyst in cracking of petroleum
  - (b) catalyst in Friedel-Crafts reaction
  - (c) mordant
  - (d) all of the above

Ans. (c)

- 11. Borax is used as a cleansing agent because on dissolving in water, it gives: [A.I.I.M.S. 2006]
  - (a) alkaline solution
- (b) acidic solution
- (c) bleaching solution
- (d) neutral solution

Ans. (a)

[Hint: Borax dissolves in water and gives an alkaline solution.

Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub> + 7H<sub>2</sub>O 
$$\Longrightarrow$$
 2NaOH + 4H<sub>3</sub>BO<sub>3</sub> ]  
Strong Weak acid

- **12.** Al<sub>2</sub>O<sub>3</sub> can be converted to anhydrous AlCl<sub>3</sub> by heating: [C.B.S.E. 2006]
  - (a) a mixture of Al<sub>2</sub>O<sub>3</sub> and carbon in dry Cl<sub>2</sub> gas
  - (b) Al<sub>2</sub>O<sub>3</sub> with Cl<sub>2</sub> gas
  - (c) Al<sub>2</sub>O<sub>3</sub> with HCl gas
  - (d) Al<sub>2</sub>O<sub>3</sub> with NaCl in solid state

Ans. (a)

[Hint:  $Al_2O_3 + 3C + 3Cl_2 \longrightarrow 2AlCl_3 + 3CO$ ]

- **13.** Boric acid is used in carrom boards for smooth gliding of pawns because:
  - (a) H<sub>3</sub>BO<sub>3</sub> molecules are loosely chemically bonded and hence soft
  - (b) its low density makes it fluffy
  - (c) it is chemically inert with the plywood
  - (d) H-bonding in  $H_3BO_3$  gives it a layered structure Ans. (d)
- 14. Boric acid is polymeric due to:
  - (a) its monobasic nature
  - (b) its acidic nature
  - (c) the presence of hydrogen bonds
  - (d) its geometry

Ans. (c)

15. The chemical formula of feldspar is:

[E.A.M.C.E.T. (Engg.) 2007]

- (a) KAlSi<sub>3</sub>O<sub>8</sub>
- (b)  $Na_3AlF_6$
- (c) NaAlO<sub>2</sub>
- (d)  $K_2SO_4\cdot Al_2(SO_4)_3\cdot 4Al(OH)_3$

Ans. (a)

**16.** The chief impurity present in red bauxite is:

[D.C.E. (Engg.) 2007]

(a) SiO<sub>2</sub>

- (b)  $Fe_2O_3$
- (c) K<sub>2</sub>SO<sub>4</sub> Ans. (b)
- (d) NaF

## **OBJECTIVE QUESTIONS**

## Set ${\bf I}$ : This set contains questions with one correct answer.

1.	The formula of corundum is:	12.	Which one is borax?	
	(a) $Al_2O_3$ $\Box$ (b) $Al_2O_3H_2O$ $\Box$		(a) $Na_2B_4O_7 \cdot 10H_2O$	
_	(c) $Al_2O_3 \cdot 2H_2O$ $\Box$ (d) $Al_2O_3 \cdot 3H_2O$ $\Box$		(c) $Ca_2B_6O_{11}.5H_2O$	
2.	Aluminium belongs to:	13.	The electrolytic reduction method for extraction of aluminis	um
	(a) s-block elements $\square$ (b) p-block elements $\square$	*	was discovered by:	
_	(c) $d$ -block elements $\square$ (d) $f$ -block elements $\square$		(a) Hoope	
3.	Aluminium forms:		(c) Baeyer	
	(a) electrovalent compounds only	14.	Cryolite is:	
	(b) covalent compounds only		(a) sodium fluoride	
	(c) electrovalent and covalent compounds both		(b) aluminium fluoride	
	(d) coordinate compounds only $\Box$		(c) sodium aluminium fluoride	
4.	Alumina is:		(d) none of the above	
	(a) acidic $\Box$ (b) basic $\Box$	15.	Which one of the following is not an ore of aluminium?	
	(c) neutral $\Box$ (d) amphoteric $\Box$	,	(a) Bauxite	
5.	The metal which evolves hydrogen, when treated with		(c) Epsomite	
	caustic soda solution is:	16.	When alumina is heated with carbon in nitrogen atmosphe	ere.
	(a) Cu		the products are:	
	(c) Ni $\square$ (d) Al $\square$		(a) $Al + CO$ $\Box$ (b) $Al + CO_2$	
6.	When aluminium is heated in atmosphere of nitrogen forms		(c) $Al + CO + CO_2$ $\Box$ (d) $AlN + CO$	
	a nitride of formula:	17.	When alumina is electrolysed in presence of cryolite, the	gas
	(a) AlN $\square$ (b) Al <sub>3</sub> N $\square$		liberated at graphite anode is:	U
	(c) $AlN_3$ $\Box$ (d) $Al_2N_3$ $\Box$		(a) $F_2$ $\Box$ (b) $O_2$	
7.	Which one of the following is most abundant in the earth's		(c) $CF_4$ $\Box$ (d) $F_2O$	
	crust?	18.	The electrolysis of pure alumina is not feasible because:	:
	(a) B		(a) it is bad conductor of electricity and its fusion temper	
^	(c) Ga		ture is high	
8.	The major role of fluorspar (CaF <sub>2</sub> ) which is added in small	,	(b) it is volatile in nature	
	quantity in the electrolytic reduction of alumina dissolved in		(c) it is decomposed when fused	
	fused cryolite, Na <sub>3</sub> AlF <sub>6</sub> , is:		(d) it is amphoteric	
	(i) as a catalyst	19.	In the extraction of aluminium, the function of cryolite is	to:
	(ii) to make the fused mixture very conducting		(a) lower the melting point of alumina	
	<ul><li>(iii) to lower the temperature of the melt</li><li>(iv) to decrease the rate of oxidation of carbon at the anode</li></ul>		(b) increase the melting point of alumina	
	(a) (i) and (ii)		(c) remove impurities from alumina	
	(c) (ii) and (iii) $\square$ (d) (i) and (iii) $\square$		(d) minimise the anodic effect	
Q	Al and Ga have nearly the same covalent radii because of:	20.	Aluminium does not react with:	
	(a) greater shielding effect of $s$ electrons of Ga atoms $\Box$		(a) NaOH	
	(b) poor shielding effect of $s$ electrons of Ga atoms $\square$		(c) $N_2$	
,	(c) poor shielding effect of $d$ electrons of Ga atoms $\Box$	21.	The common impurities present in bauxite ore are:	
	(d) greater shielding effect of $d$ electrons of Ga atoms $\Box$		(a) $Fe_2O_3$ and $CuO$ $\Box$ (b) $Fe_2O_3$ and $PbO$	
	Which of the following has the lowest melting point?		(c) $Fe_2O_3$ and $SiO_2$ $\Box$ (d) $SiO_2$ and $CuO$	
	(a) B	22.	In Hall's process, the ore is mixed with:	_
	(c) Al $\Box$ (d) Tl $\Box$		(a) coke	
11.	Which of the following is acidic in nature? [A.I.I.M.S. 2004]		(c) sodium hydroxide	
	(a) Be(OH) <sub>2</sub> $\square$ (b) Mg(OH) <sub>2</sub> $\square$	23.	Borax is prepared by treating colemanite with:	_
	(c) $AI(OH)_3$ $\Box$ (d) $B(OH)_3$ $\Box$		(a) NaNO <sub>3</sub>	
	[Hint: Mg(OH) <sub>2</sub> is a weak base and Be(OH) <sub>2</sub> and Al(OH) <sub>3</sub> are	- 24	(c) NaHCO <sub>3</sub>	
	amphoteric in nature. B(OH) <sub>3</sub> can accept one hydroxyl ion	24.	· · · · · · · · · · · · · · · · · · ·	1. <b>OT</b>

## Objective Questions for IIT ASPIRANTS

1.  $H_3BO_3 \xrightarrow{100^{\circ}C} X \xrightarrow{160^{\circ}C} Y \xrightarrow{\text{Red hot}} B_2O_3$ ;

X and Y respectively are:

- (a) X = Metaboric acid; Y = Tetraboric acid
- (b) X = Borax; Y = Metaboric acid
- (c) X = Tetraboric acid; Y = Metaboric acid
- (d) X = Tetraboric acid; Y = Borax

[Hint :H<sub>3</sub>BO<sub>3</sub>  $\xrightarrow{100^{\circ}\text{C}}$  HBO<sub>2</sub> (Metaboric acid) ; 4 HBO<sub>2</sub>  $\xrightarrow{160^{\circ}\text{C}}$   $\xrightarrow{(X)}$ 

H<sub>2</sub>B<sub>4</sub>O<sub>7</sub> (Tetraboric acid)]

- Which one of the following compounds does not exist?
  - (a)  $B_2H_4(CH_3)_2$
- (b)  $B_2H_3(CH_3)_3$
- (c)  $B_2H_2(CH_3)_4$
- (d)  $B_2H(CH_3)_5$

[Hint: Not more than four hydrogen atoms can be substituted by methyl groups in the molecule of B2H6. The bridge hydrogen atoms are not to be substituted.]

- A gas other than HCl is obtained in:
  - (a)  $BCl_3 + H_2 \xrightarrow{\text{Silent electric}}$  (b)  $LiAlH_4 + BF_3$

(d) none of these

[Hint:  $2BCl_3 + 6H_2 \xrightarrow{\text{Silent electric}} B_2H_6 + 6HCl$ ;

 $3\text{LiAlH}_4 + 4\text{BF}_3 \xrightarrow{\text{Ether}} 2\text{B}_2\text{H}_6 + 3\text{LiF} + 3\text{AlF}_3$ (Gas)

- 4. AlCl<sub>3</sub> is an electron deficient compound but AlF<sub>3</sub> is not. This is because:
  - (a) atomic size of F is smaller than Cl which makes AlF<sub>3</sub> more
  - (b) AlCl<sub>3</sub> is a covalent compound while AlF<sub>3</sub> is an ionic compound
  - (c) AlCl<sub>3</sub> exists as a dimer but AlF<sub>3</sub> does not
  - (d) Al in AlCl<sub>3</sub> is in  $sp^3$  hybrid state but Al in AlF<sub>3</sub> is in  $sp^2$
- 5. Hydride of boron occurs as B<sub>2</sub>H<sub>6</sub> but B<sub>2</sub>Cl<sub>6</sub> does not exist. This is because:
  - (a)  $p\pi$ — $d\pi$  back bonding is possible in  $B_2H_6$  but not in  $B_2Cl_6$
  - (b) boron and hydrogen have almost equal values of electronegativity
  - (c) boron and chlorine have almost equal atomic sizes
  - (d) small hydrogen atoms can easily fit in between boron atoms but large chlorine atoms do not
- **6.** Bauxite ore is generally contaminated with impurity of oxides of two elements  $E_1$  and  $E_2$ . Which of the following statements is correct?
  - (a)  $E_1$  is a non-metal and belongs to 3rd period while  $E_2$  is a metal and belong to fourth period
  - (b) One of the two oxides has three dimensional polymeric structure
  - (c) Both (a) and (b) are correct
  - (d) None of the above

- [Hint: Two oxides present in bauxite as impurity are SiO2 and Fe<sub>2</sub>O<sub>3</sub>. Si belongs to 3rd period and Fe belongs to IVth period. SiO<sub>2</sub> has three dimensional structure.]
- 7. When an inorganic compound (X) having 3C-2e as well as 2e-2e bonds reacts with ammonia gas at a certain temperature, gives a compound (Y), isostructural with benzene. Compound (X) with ammonia at a high temperature produces a substance (Z).
  - (a) (X) is  $B_2H_6$
  - (b) (Z) is known as inorganic graphite
  - (c) (Y) is  $B_3N_3H_6$
  - (d) (Z) is soft like graphite

[Hint: Diborane, B2H6, is a compound consisting 3C-2e and

2e-2e bonds.  $B_2H_6 + 2NH_3 \xrightarrow{Low \text{ temp.}} B_2H_6 \cdot 2NH_3$  $\xrightarrow{200^{\circ}\text{C}}$  B<sub>3</sub>N<sub>3</sub>H<sub>6</sub>. (Y) has structure similar to benzene. It is called inorganic benzene.  $B_2H_6 + NH_3 \xrightarrow{\text{High temp.}} (BN)_X$ .

(Z) is a hard substance.]

- Gallium has smaller atomic radius than aluminium because
  - (a) poor shielding power of d electrons of Ga atom
  - (b) poor shielding power of s electrons of Ga atom
  - (c) greater shielding power of s electrons of Al atom
  - (d) greater shielding power of d electrons of Ga atom
- 9. Boron does not form B<sup>3+</sup> cation easily. It is due to:
  - (a) energy required to form B<sup>3+</sup> ion is very high which will not be compensated by lattice energies or hydration energies of such ion
  - (b) boron is non-metal
  - (c) boron is semi-metal
  - (d) none of the above
- 10. Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O is correctly represented as:
  - (a)  $2NaBO_2 \cdot Na_2B_2O_3 \cdot 10H_2O$  (b)  $Na_2[B_4O_5(OH)_4] \cdot 8H_2O$
  - (c)  $Na_2[B_4(H_2O)_4O_7] \cdot 6H_2O$  (d) all of the above

[Hint: Borax molecule is actually made of two tetrahedra and two triangular units joined as shown below.]

Na<sub>2</sub> HO—B O—B—OH ]

- 11. Orthoboric acid behaves as a weak monobasic acid giving  $H_3O^+$  and :
  - (a)  $[B(OH)_4]^+$
- (c)  $[B(OH)_4]^-$
- (d)  $H_2BO_2$

[Hint:  $B(OH)_3 + 2H_2O \longrightarrow [B(OH)_4]^- + H_3O^+$ ]

#### 12. Amorphous boron is extracted from borax by following steps:

Borax 
$$\xrightarrow{(A)}$$
 H<sub>3</sub>BO<sub>3</sub>  $\xrightarrow{\text{Heat}}$  B<sub>2</sub>O<sub>3</sub>  $\xrightarrow{(B)}$  Boron.

- (A) and (B) are:
- (a) H<sub>2</sub>SO<sub>4</sub>, Al
- (b) HCl, carbon
- (c) H<sub>2</sub>SO<sub>4</sub>, Mg
- (d) HCl, Fe

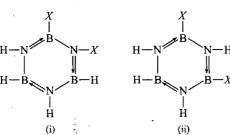

[Hint: 
$$Na_2B_4O_7 + H_2SO_4 + 5H_2O \longrightarrow Na_2SO_4 + 4H_3BO_3$$
;  
 $2H_3BO_3 \longrightarrow B_2O_3 + 3H_2O$ ;  
 $B_2O_3 + 3Mg \longrightarrow 2B + 3MgO$ ]

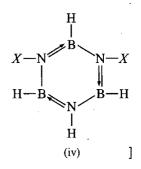

- 13. Aqueous solution of borax acts as a buffer because :
  - (a) it contains weak acid and its salt with strong base
  - (b) it contains tribasic acid and strong base
  - (c) it contains number of neutral water molecules
  - (d) none of the above

[Hint: 
$$Na_2B_4O_7 + 7H_2O \longrightarrow 2Na$$
 [B(OH)<sub>4</sub>] +  $2H_3BO_3$ ]
Salt with strong Weak acid

- 14. General formula of aluminium alums is:
  - (a)  $[M(H_2O)_6][Al(H_2O)_6][SO_4]_3$
  - (b)  $[M(H_2O)_4][Al(H_2O)_4][SO_4]_4$
  - (c)  $[M(H_2O)_4][Al(H_2O)_6][SO_4]_2$
  - (d)  $[M(H_2O)_6][Al(H_2O)_6][SO_4]_2$
- 15. The number of isomers possible for disubstituted borazine,  $B_3N_3H_4X_2$  is:
  - (a) 3
- (b) 4
- (c) 6
- (d) 5

[Hint:

Which of the statement is true for the above sequence of reactions?

- (a) Z is hydrogen
- (b) X is  $B_2H_6$
- (c) Z and Y are F<sub>2</sub> and B<sub>2</sub>H<sub>6</sub> respectively.
- (d) Z is potassium hydroxide

$$\begin{array}{ccc}
B + F_2 & \longrightarrow BF_3 \\
(Z) & (X)
\end{array}$$

$$\begin{array}{ccc} B+F_2 & \longrightarrow BF_3 & ; \\ (Z) & (X) & \\ 8BF_3+6LiH & \longrightarrow B_2H_6 + 6LiBF_4 \,] \end{array}$$

- 17. The structure of diborane (B<sub>2</sub>H<sub>6</sub>) contains: [ALE.E.E. 2005]
  - (a) four 2c-2e bonds and two 3c-2e bonds
  - (b) two 2c-2e bonds and four 3c-2e bonds
  - (c) two 2c-2e bonds and two 3c-3e bonds
  - (d) four 2c-2e bonds and four 3c-2e bonds

## ıswers

- 1. (a) 13. (a)
- 2. (d) 14. (d)
- 3. (c) 15. (b)
- 4. (b) 16. (c)
- 5. (d) 17. (a)
- 6. (c)

- **9.** (a)
- 10. (b)
- 11. (c) 12. (c)

## Assertion-Reason Type Questions

In each of the following questions two statements are given as Assertion (A) and Reason (R). Of the statements, mark the correct answer as:

- (a) If both (A) and (R) are true and (R) is the correct explanation of (A).
- (b) If both (A) and (R) are true but (R) is not the correct explanation of (A).
- (c) If (A) is true but (R) is false.
- (d) If both (A) and (R) are false.
- (e) If (A) is false but (R) is true.

- 1. (A) Borax bead test is not suitable for Al (III).
  - (R) Al<sub>2</sub>O<sub>3</sub> is insoluble in water.
- 2. (A) Thallium exhibits oxidation states of +1 and +3.
  - (R) Thallium exhibits inert pair effect.
- 3. (A) Boric acid is a tribasic acid.
  - (R) Boric acid contains three hydroxyl groups.
- 4. (A) BF<sub>3</sub> is a weaker Lewis acid than BCl<sub>3</sub>.
  - (R) BF<sub>3</sub> molecule is stabilized to a greater extent than BCl<sub>3</sub> by B—F  $\pi$ -bonding.

- 5. (A) AlCl<sub>3</sub> forms dimer Al<sub>2</sub>Cl<sub>6</sub> but it dissolves in water forming [Al(H<sub>2</sub>O)<sub>6</sub>]<sup>3+</sup> and Cl<sup>-</sup> ions.
  - (R) Aqueous solution of AlCl<sub>3</sub> is acidic due to hydrolysis.
- 6. (A) Aluminium is used as a reducing agent in thermite process.
  - (R) Aluminium can reduce Na<sub>2</sub>O to sodium.

- 7. (A) In water, orthoboric acid behaves as a weak monobasic acid.
  - (R) In water, orthoboric acid acts as a proton donor.

[LLT. 2007]

- (A) Boron always forms covalent bond.
  - The small size of B<sup>3+</sup> favours formation of covalent bond. [LI.T. 2007]

# THOUGHT TYPE QUESTIONS

#### THOUGHT 1

Aluminium is stable in air and water inspite of the fact that it is reactive metal. The reason is that a thin film of its oxide is formed on its surface which makes it passive for further attack. The layer is so useful that in industry, it is purposely deposited by an electrolytic process called anodising.

Reaction of aluminium with oxygen is highly exothermic and is called thermite reaction.

$$2Al(s) + \frac{3}{2}O_2(g) \longrightarrow Al_2O_3(s); \qquad \Delta H = -1670 \text{ kJ}$$

Thermite reaction finds applications in the metallurgical extraction of many metals from their oxides and for welding of metals. The drawback is that to start the reaction, high temperature is required for which an ignition mixture is used.

- 1. Anodising can be done by electrolysing dilute H<sub>2</sub>SO<sub>4</sub> with aluminium as anode. This results in:
  - (a) the formation of  $Al_2(SO_4)_3$  on the surface of aluminium
  - (b) the formation of oxide film (Al<sub>2</sub>O<sub>3</sub>) on the surface of aluminium anode
  - (c) the formation of polymeric aluminium hydride film on the surface of aluminium anode
  - (d) none of the above
- 2. The reaction which is not involved in thermite process:
  - $3Mn_3O_4 + 8Al \longrightarrow 9Mn + 4Al_2O_3$
  - $Cr_2O_3+2Al \longrightarrow 2Cr + Al_2O_3$ (b)
  - $2Fe + Al_2O_3 \longrightarrow Fe_2O_3 + 2Al$ (c)
  - $B_2O_3 + 2Al \longrightarrow 2B + Al_2O_3$
- 3. Thermite a mixture used for welding is:
  - (a) Fe and Al
    - (b) BaO and Mg powder
  - (c) Cu and Al (d) Fe<sub>2</sub>O<sub>3</sub> and Al powder
- 4. Anodised aluminium is:
  - (a) Al obtained at anode
  - (b) Al prepared electrolytically
  - (c) alloy of Al containing 95% Al
  - (d) Al electrolytically coated with aluminium oxide

- 5. Which one of the following metals cannot be extracted by using Al as a reducing agent?
  - (a) Na from Na<sub>2</sub>O
- (b) Cr from Cr<sub>2</sub>O<sub>3</sub>
- (c) W from WO<sub>3</sub>
- (d) Mn from Mn<sub>3</sub>O<sub>4</sub>
- Aluminium becomes passive in:
  - (a) conc. HNO<sub>3</sub>
- (b) H<sub>2</sub>CrO<sub>4</sub>
- (c) HClO<sub>4</sub>
- (d) all of these

THOUGHT 2
$$Ca_{2}B_{6}O_{11} + Na_{2}CO_{3} \xrightarrow{\text{Fused}} (A) + (B) + CaCO_{3}$$

$$(A) + CO_{2} \longrightarrow (B) + Na_{2}CO_{3}$$
Solution
$$(B) + \text{Conc. HCl} \longrightarrow \text{NaCl} + \text{Acid}$$

$$(C) \xrightarrow{\text{Strongly}} (D) \qquad \text{Acid } (C)$$

- (D) + CuSO<sub>4</sub>  $\xrightarrow{\text{Heated}}$  Blue coloured (E) compound
- 1. Compound (A) is:
  - (a) NaBO<sub>2</sub>
- (b) Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>
- (c) Na<sub>3</sub>BO<sub>3</sub>
- (d) NaOH
- **2.** Compound (*B*) is :
  - (a) NaBO<sub>2</sub>
- (b)  $Na_2B_4O_7$
- (c) Na<sub>3</sub>BO<sub>3</sub>
- (d) NaOH
- 3. Compound (C) is:
  - (a)  $H_2B_4O_7$
- (b) HBO<sub>2</sub>
- (c)  $H_3BO_3$
- (d) HB<sub>3</sub>O<sub>5</sub>
- **4.** Compound (D) is:
  - (a) H<sub>3</sub>BO<sub>3</sub>
- (b)  $B_2O_3$

(c) B

- (d) none of these
- **5.** Compound (E) is:
  - (a) Cu<sub>2</sub>O
- (b) CuS
- (c) CuSO<sub>3</sub>
- (d)  $Cu(BO_2)_2$

## THOUGHT 3

(i) Boron + 
$$O_2 \xrightarrow{700^{\circ}C} (X)$$

(ii) 
$$(X) + C$$
 (carbon) +  $Cl_2 \longrightarrow (Y) + CO$ 

(iii) 
$$(Y)$$
 + LiAlH<sub>4</sub>  $\longrightarrow$   $(Z)$  + LiCl + AlCl<sub>3</sub>

$$(iv)(Z) + NH_3 \longrightarrow (A) \xrightarrow{Heat} (B)$$

(v) (Z) + NaH 
$$\longrightarrow$$
 (D)

- 1. Compound (Z) is:
  - (a) an ionic compound
  - (b) an electron deficient compound
  - (c) 3C—2e compound
  - (d) having ethane like structure
- Compounds (X) and (Y) are:

(a) 
$$(V) = PO$$
  $(V) = PC$ 

(a) 
$$(X) = BO_2$$
,  $(Y) = BCl_2$  (b)  $(X) = BO_3$ ,  $(Y) = BCl_4$ 

(c) 
$$(X) = B_2O_3$$
,  $(Y) = BCl_3$  (d)  $(X) = BO_3$ ,  $(Y) = B_4C$ 

(d) 
$$(X) = BO_3$$
,  $(Y) = B_4C$ 

- **3.** Compound (*B*) is :

  - (a) borazole (b) inorganic benzene
  - (c) borazon
- (d) boron nitride
- Compound (D) is used as a/an:
  - (a) oxidising agent
- (b) complexing agent
- (c) buffer agent
- (d) reducing agent

[Hint:  $B_2H_6 + 2NaH \longrightarrow 2NaBH_4$  (sodium borohydride). It is used as a reducing agent.]

- Compound Y:
  - (a) has boron in  $sp^2$  hybridized state
  - (b) is a planar molecule

- (c) has zero dipole moment
- (d) is a Lewis base

[Hint: BCl<sub>3</sub>—B in  $sp^2$  state, triangular planar structure and zero dipole moment being symmetrical molecule. It is a Lewis

#### **THOUGHT 4**

Boron forms a number of hydrides having the general formulae  $B_nH_{n+4}$  and  $B_nH_{n+6}$ . These hydrides are called boranes. The simplest hydride of boron is diborane, B2H6. Boranes contain special types of bonds known as multicentre bonds. Boranes have high heat of combustion.

- 1. The type of hybridization of boron in diborane is:
  - (a) sp
- (b)  $sp^2$
- (c)  $sp^3$
- Three centre two electron bond is present in:
  - (a) BF<sub>3</sub>
- (b)  $B_4H_{10}$
- (c) H<sub>3</sub>BO<sub>3</sub>
- (d)  $B_2H_6$
- 3. Which of the following is electron deficient compound?
  - (a)  $C_2H_6$
- (b) SiH<sub>4</sub>

- (c) PH<sub>3</sub>
- (d)  $B_4H_{10}$
- Which hydride does not exist?
  - (a) BH<sub>3</sub>

- (b)  $H_2F_2$
- (c) SbH<sub>3</sub>

- (d) N<sub>2</sub>H<sub>4</sub>
- 5. From  $B_2H_6$ , all the following can be prepared except:
  - (a)  $H_3BO_3$
- (b)  $B_2(CH_3)_4H_2$
- (c)  $B_2(CH_3)_6$
- (d) NaBH<sub>4</sub>

- $In B_2H_6$ :
  - (a) there is direct boron-boron bond
  - (b) the boron atoms are linked through hydrogen bridges
  - (c) all the B—H bond distances are equal
  - (d) all the atoms are in one plane

,

## BRAIN STORMING PROBLEMS

- 1. What are special features of structure of boron?
  - [Hint: It is a symmetrical solid with icosahedral shape. There are 20 faces (equilateral triangle). The faces meet at 12 corners. Each icosahedron consist of 12 boron atoms; six of them are bonded to another icosahedron by two centre bond (1.71 Å); each of other six is bonded by a three centre bond (2.02 Å) in separated icosahedra.]
- Which alloy of aluminium is used in air-craft industry? [Ans. Duralumin]
- 3. Aluminium vessels should not be cleaned by washing soda. explain why?

[Ans. Na<sub>2</sub>CO<sub>3</sub> undergo hydrolysis to give NaOH. Sodium hydroxide react with aluminium vessels.

$$2A1 + 2NaOH + 2H_2O \longrightarrow 2NaAlO_2 + 3H_2$$

4. Can we prepare anhydrous AlCl<sub>3</sub> by heating AlCl<sub>3</sub>·6H<sub>2</sub>O?

[Ans. When AlCl<sub>3</sub>·3H<sub>2</sub>O is heated, hydrolysis takes place.

$$2AlCl_3 \cdot 6H_2O \longrightarrow 2Al(OH)_3 + 6HCl_2Al(OH)_3 \longrightarrow Al_2O_3 + 3H_2O_1$$

5. When finely powdered aluminium is suddenly exposed to air, it catches fire, explain why?

[Ans. Aluminium powder undergo exothermic oxidation, therefore, it catches fire and becomes hazardous.

$$2Al + \frac{3}{2}O_2 \longrightarrow Al_2O_3$$
;  $\Delta H = -ve (-310 \text{ kJ/mol})$ 

6. Boric acid is weak, it cannot be titrated directly with NaOH. Give the precautions taken in the titration of boric acid with caustic soda.

[Ans. When catechol is added to boric acid, stable compound (strong acid) is formed, which can be titrated with caustic soda using methyl orange indicator.]

7. What do you understand by?

(a) Ammonal

(b) Bentonite

(c) Rubies and Sapphire

(d) Lapis Lazuli

[Hint:

(a) Ammonal: It is mixture of  $\{Al + NH_4NO_3\}$ , used in bombs.

- (b) Bentonite: Alumina-silica clay called 'bentonite' is dropped from aeroplanes in the slury form for spreading water over fires.
- (c) Rubies and sapphire are chemically Al<sub>2</sub>O<sub>3</sub>. These are gems.
- (d) Lapis Lazuli is sodium alumino silicate, which is used as semiprecious stone.]
- **8.** Give the name and structural formula of a boron compound which is optically active.

[Ans. Boro salicylic acid is optically active.]
[Hint:

9. What is the chemical composition of Emery Paper?

[Ans. Impure form of corundum (Al<sub>2</sub>O<sub>3</sub>) containing impurity of Fe<sub>2</sub>O<sub>3</sub> and silica is called Emery and it is used in the manufacture of emery paper or sand paper. This paper is used to polish metals.]

10. Discuss the structure of tricalcium aluminate, which is important constituent of portland cement.

[Hint: General formula = Ca<sub>9</sub>[Al<sub>6</sub>O<sub>18</sub>]. It contains twelve membered rings of Si—O—Si—O bonds made by joining six AlO<sub>4</sub> tetrahedra.]

11. Complete the following reactions:

(i) 
$$BCl_3 + (C_2H_5)_4 \stackrel{+}{N}Cl^- \xrightarrow{CHCl_3}$$
 ?

(ii) 
$$NH_4Cl + Na_2B_4O_7 \xrightarrow{Red hot} ?$$

(iii) 
$$BCl_3 + NH_4Cl \xrightarrow{-140^{\circ}C} ? \xrightarrow{NaBH_4} ?$$

[Ans. (i) 
$$-BCl_3 + (C_2H_5)_4NCl^- \xrightarrow{CHCl_3} [(C_2H_5)_4N]BCl_4$$

(ii) 
$$NH_4Cl + Na_2B_4O_7 \xrightarrow{Red hot} 2BN + B_2O_3 + 2NaCl + 2H_2O_3 + 2H_2O$$

(iii) 
$$3BCl_3 + 3NH_4Cl \xrightarrow{140^{\circ}C} B_3N_3H_3Cl_3$$

 $\xrightarrow{\text{NaBH}_4} \text{B}_3\text{N}_3\text{H}_6 \text{ (Borazine)}]$ 

## INTEGER ANSWER Type Otlestions:

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

- 1. How many orbitals of boron are involved in hybridisation in diborane?
- **2.** How many moles of methane are obtained by hydrolysis of one mole of aluminium carbide?
- 3. Colemanite is an important mineral of boron. It is represented  $Ca_2B_xO_{11}\cdot 6H_2O$ . What is the value of x?
- **4.** Borax is represented as Na<sub>2</sub>[B<sub>4</sub>O<sub>5</sub>(OH)<sub>4</sub>]·8H<sub>2</sub>O. How many tetrahedral boron atoms are present in the structure of borax?
- 5. How many isomers of disubstituted borazine are possible?
- **6.** How much nitrogen is evolved when one gram of ammonium chloride is heated with borax strongly?
- 7. The mass of carbon anode consumed (giving only CO<sub>2</sub>) in the production of 27 kg of aluminium metal from bauxite by electrolytic method is:

## Auswers

- 1. (4) Each boron atom in  $B_2H_6$  is in  $sp^3$ -hybridised state. Thus, four orbitals are involved in hybridisation.
- 2. (3)  $Al_4C_3 + 12H_2O \longrightarrow 4Al(OH)_3 + 3CH_4$ 1 mole 3 moles
- 3. (6)  $Ca_2B_6O_{11}.5H_2O$
- **4.** (2) Borax has two tetrahedral and two triangular units joined together.

$$Na_{2} \begin{bmatrix} OH & & & & & \\ & I & & & & \\ O-B & O-B-O & & & \\ O-B-O & & & & \\ OH & & & OH \end{bmatrix}$$

5. (4) Four isomers are possible. [See Q. No. 15 on page 404]

6. (0) No nitrogen is evolved in this reaction.  $2NH_4Cl + Na_2B_4O_7 \cdot 10H_2O \longrightarrow 2NaCl + 2BN + B_2O_3 + 14H_2O$ 

7. (9) 
$$2Al_2O_3 + 3C \longrightarrow 4Al + 3CO_2$$

Group IVA or 14

# **Elements of Group IVA or 14**

(Elements of Carbon Family,  $ns^2np^2$ )

### 9.1 POSITION IN PERIODIC TABLE

Group IVA or 14 of long form of periodic table consists of six elements—carbon (C), silicon (Si), germanium (Ge), tin (Sn), lead (Pb) and ununquadium\*. These six elements constitute a family known as carbon family. These are p-block elements as the last differentiating electron is accommodated in np shell. These elements have four electrons in their valency shell and thus placed in the IVth group. The elements of this group show similarities as well as gradation in properties with rise of atomic number and thus their inclusion in the same group is justified on the basis of electronic configuration and physical and chemical properties which are described below:

Group	ША	IVA	VA	
Period	13	14	15	
2	B (5)	C (6)	N (7)	
3	Al (13)	Si (14)	P (15)	
4	Ga (31)	Ge (32)	As (33)	
5	In (49)	Sn (50)	Sb (51)	
6	T1- (81)	Pb (82)	Bi , (83)	
7	Uut (113)	Uuq (114)	Uup (115)

**1. Electronic configuration :** The electronic configuration of the members of this group are:

Element	At. No.		Electronic configuration	Inert gas core
Carbon	6	2, 4	$1s^2$ , $2s^2$ $2p^2$	[He] $2s^2 2p^2$
Silicon	14	2, 8, 4	$1s^2$ , $2s^2 2p^6$ , $3s^2 3p^2$	[Ne] $3s^2 3p^2$
Germanium	32	2, 8, 18, 4	$1s^2$ , $2s^2 2p^6$ , $3s^2 3p^6 3d^{10}$ , $4s^2 4p^2$	[Ar] $3d^{10}$ , $4s^2 4p^2$
Tin	50	2, 8, 18, 18, 4	$1s^2$ , $2s^2 2p^6$ , $3s^2 3p^6 3d^{10}$ , $4s^2 4p^6 4d^{10}$ , $5s^2 5p^2$	[Kr] $4d^{10}$ , $5s^2$ $5p^2$
Lead	82	2, 8, 18, 32, 18, 4	$1s^2$ , $2s^2 2p^6$ , $3s^2 3p^6 3d^{10}$ , $4s^2 4p^6 4d^{10} 4f^{14}$ , $5s^2 5p^6 5d^{10}$ , $6s^2 6p^2$	[Xe] $4f^{14}$ , $5d^{10}$ , $6s^2 6p^2$
Ununquadium	114	2, 8, 18, 32, 32, 18, 4	$1s^2$ , $2s^2 2p^6$ , $3s^2 3p^6 3d^{10}$ , $4s^2 4p^6 4d^{10} 4f^{14}$ , $5s^2 5p^6 5d^{10} 5f^{14}$ ,	[Rn] $5f^{14}$ , $6d^{10}$ , $7s^2 7p^2$
			$6s^2 6p^6 6d^{10}, 7s^2 7p^2$	

<sup>\*</sup>Recently a new element of this group with atomic number 114 (IUPAC name ununquadium) has been discovered.

The configurations show that these elements have same number of electrons in the valency shell, *i.e.*, 4 electrons in the valency shell, two of which are in s-orbital while remaining two in p-orbitals. Thus, they have  $ns^2 np^2$  configuration, *i.e.*, s-orbital is paired while two p-orbitals are unpaired.

$$\begin{array}{c|c}
ns & np \\
\hline
\uparrow\downarrow & \uparrow & \uparrow
\end{array}$$

The penultimate shell of carbon contains 2 electrons (saturated), of silicon contains 8 electrons (saturated), of germanium contains 18 electrons (saturated) while Sn and Pb contain 18 electrons (unsaturated) each. This shows why carbon differs from silicon in some respects and these two differ from rest of the members of this group. The close resemblance between the elements is quite striking in the case of elements of the first and second groups, but this becomes less evident in the elements of third group and still less evident in the fourth group. It shall be clear from the following discussion.

2. Occurrence of the elements: Carbon is extremely wide spread in nature. It is an essential constituent of all living matter as proteins, carbohydrates and fats. Carbon is the seventeenth and silicon the second most abundant element by mass in the earth's crust. Carbon is found both in native and combined states. Silicon occurs very widely as silica and a wide variety of silicate minerals and clays. Germanium is only found in traces in some silver and zinc ores, and in some types of coal. No doubt that the abundance of tin and lead is comparatively low, but they occur as concentrated ores. Tin is mined as cassiterite, SnO<sub>2</sub> and lead is found as galena ore, PbS. In the fusion reactions occurring on stars and sun, carbon acts as catalyst. The energy released in the process is called stellar energy.

The last member, ununquadium (114) is recently discovered element. It is synthetic, radioactive and unstable element. Not much is known about its properties.

**3. Non-metallic and metallic character:** The change from non-metallic to metallic character with the increase of atomic number is best illustrated by this group. Carbon, the first element, is a non-metal, silicon, the second element has most of the properties of a non-metal but its electrical properties and some of the physical properties are those of a semi-metal (metalloid). Germanium is a metalloid (properties are mixed, *i.e.*, of a metal and a non-metal) while last two members Sn and Pb are distinctly metals.

The change from non-metallic to metallic character is due to less effective nuclear charge and increased number of available orbitals with increase in the size of the atom.

**4. Atomic radii and atomic volume:** Atomic radii and atomic volume increase gradually on moving down the group. The size increases due to the effect of extra shell being added from member to member.

	C	Si	Ge	Sn	Pb
Atomic radius (pm)	77	118	122	140	146
At. volume (mL)	3.4	11.4	13.6	16.3	18.27

It is observed that there is large increase in atomic radius from carbon to silicon but from silicon onwards, the increase is comparatively small from member to member. This is due to the fact that shielding effect of  $s^2p^6$  electrons of the penultimate shell in silicon is large while the shielding effect of  $d^{10}$  electrons in Ge and Sn and  $d^{10}$ ,  $f^{14}$  electrons in Pb is less.

In the same period, the atomic radii of group 14 elements are smaller than the corresponding elements of group 13. This is due to fact that effective nuclear charge increases when we move from group 13 to group 14. This brings contraction in size.

$$C < B$$
 ;  $Si < Al$  ;  $Ge < Ga$  (77 pm) (85 pm) (118 pm) (143 pm) (122 pm) (135 pm)

**5. Ionisation potential:** The ionisation potentials decrease gradually from carbon to lead but not systematically as in groups I and II. The value of lead is slightly higher than expected due to lanthanide contraction.

~		C	Si	Ge	Sn	Pb
Ionisation	$\Delta_i H_1$	1086	786	761	708	715
enthalpy	$\Delta_i H_2$	2352	1577	1537	1411	1450
$(kJ \text{ mol}^{-1})$	$\Delta_i H_3$	4620	3228	3300	2942	3081
	$\Delta_i H_4$	6220	4354	4409	3929	4082

Large decrease in ionisation potential from C to Si is due to increase in size of the atom. Decrease in ionisation potential from silicon onwards is comparatively smaller due to less screening effect of  $d^{10}$  electrons in Ge and Sn and due to  $d^{10}f^{14}$  electrons in Pb.

The slight increase in the ionisation energy from Sn to Pb is due to lanthanide contraction and increase of 32 units of nuclear charge in Pb over Sn, *i.e.* valency electrons are more tightly held in Pb.

The first ionisation energies of group 14 are higher than the corresponding elements of group 13 in the same period.

The increase is due to decrease in size and increase in charge on nucleus of group 14 elements in the same period.

**6. Melting and boiling points:** Carbon has an extremely high melting point (4100°C). Silicon melts appreciably lower than carbon but the values of silicon and germanium are still high. (Si = 1420°C; Ge = 945°C). They have the very stable diamond like structure in which smaller atoms are closely packed. Tin and lead are metallic and have much lower melting points (Sn = 232°C; Pb = 327°C) because the *M*—*M* bonds are weaker. They do not use all the four outer electrons for metallic bonding.

The boiling point of carbon is exceedingly high. It decreases in silicon and then increases in germanium. However, the boiling point decreases from germanium to lead. 7. Electronegativity: The electronegativity values do not decrease in a regular manner. Carbon is the most electronegative element while Si, Ge, Sn and Pb possess nearly the same values. This is due to filling of d-orbitals in Sn and Ge and also f-orbitals in lead.

- **8. Allotropy:** Except lead, all other elements of this group show allotropy. For example, carbon exists as diamond, graphite, coal, charcoal and lampblack; silicon exists in two forms, crystalline and amorphous; germanium exists in two crystalline forms and tin exists in three forms; grey tin, white tin and rhombic tin.
- **9. Valency:** All these elements show a covalency of 4. The tetravalency is explained on the basis of the shifting of one of the paired *ns* electrons to the vacant *np* orbital in the same shell.

Ground state 
$$\begin{array}{c|c}
ns & np \\
\uparrow\downarrow & \uparrow\uparrow \uparrow
\end{array}$$
Excited state 
$$\begin{array}{c|c}
sp^3 \text{ hybridization}
\end{array}$$

These four half filled orbitals mix together to give four  $sp^3$  hybrid orbitals resulting in a tetrahedral structure and each having one unpaired electron.

When  $ns^2$  electrons of outermost shell do not participate in bonding it is called inert pair and the effect is called inert pair effect. The last three elements have a tendency to form  $M^{2+}$  ions as well as  $M^{4+}$  ions. Since, the inert pair effect increases from Ge to Pb, the stability of  $M^{4+}$  ions decreases and that of  $M^{2+}$  ions increases. Thus, the stability of these ions follows the following order:

$$Ge^{2+} < Sn^{2+} < Pb^{2+}$$
  
 $Ge^{4+} > Sn^{4+} > Pb^{4+}$ 

The compounds of Ge<sup>2+</sup> are unstable while compounds of Ge<sup>4+</sup> are stable. Thus, the compounds of Ge<sup>2+</sup> get oxidised into Ge<sup>4+</sup> easily and act as reducing agents.

$$\begin{array}{ccc} Ge^{2+} & \xrightarrow{-2e} & Ge^{4+} \\ \text{Less stable} & \text{More stable} \\ \text{(Reducing agent)} & \end{array}$$

The compounds of  $\mathrm{Sn}^{2+}$  are less stable than  $\mathrm{Sn}^{4+}$ . Thus,  $\mathrm{Sn}^{2+}$  compounds also act as reducing agents. In the case of lead,  $\mathrm{Pb}^{2+}$  compounds are more stable than  $\mathrm{Pb}^{4+}$  compounds. The  $\mathrm{Pb}^{4+}$  compounds, thus, act as oxidising agents.

$$\begin{array}{ccc} \text{Pb}^{4+} & + & 2e \longrightarrow & \text{Pb}^{2+} \\ \text{Less stable} & & \text{More stable} \\ \text{(Oxidising agent)} & & & \end{array}$$

Since  $M^{4+}$  ions are smaller than  $M^{2+}$  ions, in general,  $M^{4+}$  compounds behave as covalent due to high polarisation (small size and high charge) and  $M^{2+}$  compounds are ionic.

10. Multiple bonding: Carbon, the first member of group 14, possesses a pronounced ability to form stable  $p\pi$ – $p\pi$  multiple bonds (double and triple bonds) with itself and with other first row elements such as nitrogen and oxygen. The compounds containing C = C, C = C, C = C, and

C=S bonds are common. Graphite, an allotropic form of carbon, is also an example of  $p\pi-p\pi$  bonding. Silicon and other elements of this group show their reluctance in forming  $p\pi-p\pi$  multiple bonding due to their large atomic sizes. However, silicon and other elements of this group have vacant d-orbitals in their valence shell. These elements can form  $d\pi-p\pi$  double bonds with nitrogen and oxygen. This bond is formed by the donation of an electron pair from filled 2p-orbitals of N or O to the vacant 3d-orbitals of silicon or other elements of group 14. The existence of  $d\pi-p\pi$  bonding explains the structures of trimethylamine, (CH<sub>3</sub>)<sub>3</sub>N, and trisilylamine N(SiH<sub>3</sub>)<sub>3</sub> and their basic nature.

In trimethylamine, the N atom undergoes  $sp^3$ -hybridisation giving tetrahedral configuration. The geometry of the molecule is **pyramidal** as one of the tetrahedral positions is occupied by a lone pair.  $p\pi$ - $d\pi$  bonding cannot occur in this molecule as carbon does not have d-orbitals. This lone pair,  $N(CH_3)_3$ , can be donated to Lewis acids and thus it shows a basic nature. In trisilylamine,  $sp^2$ -hybridisation occurs giving **trigonal planar** geometry to the molecule. The lone pair of electrons is present in unhybridised p-orbital. This overlaps with empty d-orbital of any one of the silicon atoms forming  $p\pi$ - $d\pi$  back bonding. Due to non-availability of lone pair, this molecule does not show basic nature.

**11. Catenation:** The linking of identical atoms with each other to form long chains is called **catenation.** All the elements of this group have the property of catenation. However, this property decreases from carbon to lead. Thus, carbon has the maximum property of catenation, silicon has much lesser tendency, germanium has still lesser tendency whereas tin and lead hardly show this property. The decrease of this property is associated with M—M bond energy which decreases from carbon to lead.

C—C	83 kcal/mol
Si—Si	54 kcal/mol
Ge—Ge	40 kcal/mol
SnSn	37 kcal/mol

The reason for greater tendency of carbon for catenation than other elements may further be explained by the fact that C—C bond energy is approximately of the same value as the energies of bonds between carbon and other elements. On the other hand Si—Si bond is weaker than the bonds between silicon and other elements.

C—C	83 kcal/mol	Si—Si	54 kcal/mol
C—O	86 kcal/mol	Si—O	88 kcal/mol
C—Cl	81 kcal/mol	Si—C	186 kcal/mol

Thus, carbon forms a number of compounds in which a large number of carbon atoms are linked together in the form of straight chains, branched chains or closed rings. The property of catenation is responsible for a very large number of compounds of carbon.

**12. Maximum covalency:** Carbon has only two energy shells, K and L. L shell (outermost shell) has four orbitals 2s,  $2p_x$ ,  $2p_y$  and  $2p_z$ . These four orbitals can accommodate a maximum of 8 electrons forming four covalent bonds. Thus, maximum covalency of carbon is four because it has no d-orbitals or vacant orbitals which can be used to accommodate more electrons.

The remaining elements, however, have vacant *d*-orbitals. These permit the formation of coordinate bonds with other atoms or ions having lone pairs of electrons. For example, SiF<sub>4</sub> can combine with 2F<sup>-</sup> ions.

$$SiF_4 + 2F^- \longrightarrow [SiF_6]^{2-}$$

Thus, the maximum covalency of silicon can be 6. Similarly, other members can show maximum covalency of six involving  $sp^3d^2$  hybridization.

Since all these elements except carbon satisfy the following three conditions for the formation of complexes, they have the tendency to form complexes using *d*-orbitals.

- (i) small size of the atom or ion
- (ii) high charge
- (iii) availability of vacant orbitals of appropriate energy.
- 13. Reactivity: The elements of this group are relatively less reactive but reactivity increases down the group. Lead often appears more unreactive than expected. This is partly due to surface coating of the oxide and partly due to the high overpotential for the reduction of  $H^+$  to  $H_2$  at a lead surface.
- (i) Reactivity towards air: These elements react with the oxygen of the air on strong heating when their oxides are formed.

$$C + O_2 \longrightarrow CO_2$$
;  $Si + O_2 \longrightarrow SiO_2$   
 $Ge + O_2 \longrightarrow GeO_2$ ;  $2Pb + O_2 \longrightarrow 2PbO$ 

Mono-oxides CO, SiO, GeO are also known. SiO is unstable.

(ii) Reactivity towards water: C, Si and Ge are unaffected by water. However, on red heating, these elements except lead decompose steam.

$$C + H_2O \longrightarrow CO + H_2$$
  
 $Si + 2H_2O \longrightarrow SiO_2 + 2H_2$   
 $Sn + 2H_2O \longrightarrow SnO_2 + 2H_2$ 

Lead is unaffected by water, probably, because of a protective oxide film.

(iii) Reactivity towards acids: Non-oxidising acids do not attack carbon and silicon. Germanium is not attacked by dilute HCl. However, when metal is heated in a stream of HCl gas, germanium chloroform is formed.

$$Ge + 3HCl \longrightarrow GeHCl_3 + H_2$$

Tin dissolves slowly in dilute HCl but readily in concentrated HCl.

$$Sn + 2HC1 \longrightarrow SnCl_2 + H_2$$

Lead also dissolves in dilute HCl.

Lead dissolves in concentrated HCl forming chloroplumbous acid, but the reaction stops after sometime due to deposition of PbCl<sub>2</sub>.

$$Pb + 2HCl \longrightarrow PbCl_2 + H_2$$
  
 $PbCl_2 + 2HCl \longrightarrow H_2PbCl_4$ 

Tin dissolves in dilute H<sub>2</sub>SO<sub>4</sub>, conc. H<sub>2</sub>SO<sub>4</sub>, dil. HNO<sub>3</sub> and conc. HNO<sub>3</sub>.

$$Sn + H_2SO_4$$
 (dil.)  $\longrightarrow SnSO_4 + H_2$   
 $Sn + 4H_2SO_4$  (conc.)  $\longrightarrow Sn(SO_4)_2 + 2SO_2 + 4H_2O$   
 $4Sn + 10HNO_3$  (dil.)  $\longrightarrow 4Sn(NO_3)_2 + NH_4NO_3 + 3H_2O$   
 $Sn + 4HNO_3$  (conc.)  $\longrightarrow H_2SnO_3 + 4NO_2 + H_2O$   
Metastannic  
acid

Lead is not affected by dil. H<sub>2</sub>SO<sub>4</sub>. Hot conc. H<sub>2</sub>SO<sub>4</sub> dissolves lead but the reaction becomes slower due to formation of insoluble PbSO<sub>4</sub>.

$$Pb + 2H_2SO_4 \longrightarrow PbSO_4 + SO_2 + 2H_2O$$

 $HNO_3$  is the best solvent for lead.

$$3Pb + 8HNO_3 (dil.) \longrightarrow 3Pb(NO_3)_2 + 2NO + 4H_2O$$

$$Pb + 4HNO_3 (conc.) \longrightarrow Pb(NO_3)_2 + 2NO_2 + 2H_2O$$

Organic acids dissolve lead in presence of oxygen.

$$Pb + 2CH_3COOH + 1/2 O_2 \longrightarrow Pb(CH_3COO)_2 + H_2O$$

(iv) Reactivity towards alkalies: Carbon is unaffected by alkalies. Silicon reacts slowly with cold aqueous NaOH and readily with hot solution giving solution of silicate.

$$Si + 2NaOH + H_2O \longrightarrow Na_2SiO_3 + 2H_2$$

Sn and Pb are slowly attacked by cold alkali but readily by hot alkali giving stannates and plumbates. Thus, Sn and Pb are somewhat amphoteric.

$$Sn + 2NaOH + H_2O \longrightarrow Na_2SnO_3 + 2H_2$$
  
 $Pb + 2NaOH + H_2O \longrightarrow Na_2PbO_3 + 2H_2$ 

#### 14. Compounds:

(i) Hydrides: All the members of this group form covalent hydrides directly or indirectly. The number of hydrides, their stability and the case of formation decreases as we move down from carbon to lead. However, all the members form hydrides of the type  $M \, H_4$ . Besides  $M \, H_4$ , carbon forms a large number of hydrides, saturated as well as unsaturated. Silicon forms only limited number of saturated hydrides. Germanium gives a still smaller number of hydrides while Sn and Pb give only one hydride each.

The hydrides of  $MH_4$  type are gaseous and their thermal stability decreases and consequently the reducing nature increases from top to bottom. However, among the hydrides, silicon hydrides are least stable to hydrolysis.

Hydrides CH<sub>4</sub> SiH<sub>4</sub> GeH<sub>4</sub> SnH<sub>4</sub> PbH<sub>4</sub> Decomposition temp.(°C) 800 450 285 150 0

[The hydrides of silicon (silanes) are much more reactive than the alkanes. The difference in behaviour is attributed to various factors:

(a) Electronegativity values are: C = 2.5, Si = 1.8 and H = 2.1. Thus, the bonding electrons between C and H or Si and H are not equally shared and silicon is vulnerable to attack by nucleophilic reagents.

$$\delta^- \delta^+ \qquad \delta^+ \delta^-$$
  
C—H Si—H

- (b) The larger size of Si is easier to be attacked.
- (c) Si has low energy d-orbitals which may be used to form an intermediate compound and thus lower the activation energy of the process.

$$SiH_4 + 2NaOH + H_2O \longrightarrow Na_2SiO_3 + 4H_2$$
  
 $SiH_4 + 3H_2O \longrightarrow H_2SiO_3 + 4H_2$   
 $SiH_4 + 4AgNO_3 \longrightarrow Si + 4Ag + 4HNO_3$   
 $SiH_4 + 2Cl_2 \longrightarrow Si + 4HCl$ 

The low stability of  $GeH_4$ ,  $SnH_4$  and  $PbH_4$  is due to weak M—H bond. It is due to large difference in the size of M and hydrogen atom leading to poor overlapping and weak covalent bond.

[Note: Extremely pure silicon can be obtained by pyrolysis of monosilane, SiH<sub>4</sub>, in absence of air. The pure silicon is used as a semiconductor.

$$SiCl_4 \xrightarrow{LiAlH_4} SiH_4 \xrightarrow{Heat in absence of air} Si(Pure)$$

(ii) Halides: The members of this group form tetrahalides of the type  $MX_4$  except PbBr<sub>4</sub> and PbI<sub>4</sub>. The halides are covalent and formed by  $sp^3$  hybridization. The thermal stability of halides of different elements with a common halogen decreases with increasing atomic number. The thermal stability of tetrahalides of the same element decreases with increase in molecular mass of the tetrahalide.

$$CX_4 > SiX_4 > GeX_4 > SnX_4 > PbX_4$$
  
 $CF_4 > CCl_4 > CBr_4 > CI_4$ 

$$\begin{array}{c} Cl & | Cl | H | \\ Cl & | O - H \\ Cl - Si - Cl + 2H_2O \longrightarrow Cl - Si - Cl & \xrightarrow{+H_2O} \\ Cl & | H - O \\ Cl & | H - Cl | \end{array}$$

$$\begin{array}{c|c} OH & OH \\ \hline OH & \hline OH & OH \\ \hline CI-Si-Cl \xrightarrow{+2H_2O} Cl \xrightarrow{+2H_2O} Cl \xrightarrow{+2H_2O} Cl \xrightarrow{+2H_2O} OH \\ \hline OH & OH & OH \\ \hline OH & OH & OH \\ \hline \end{array}$$

[Non-existence of PbBr<sub>4</sub> and PbI<sub>4</sub> can be explained on the basis of strong oxidising nature of Pb<sup>4+</sup>. The ions Br<sup>-</sup> and I<sup>-</sup> are reducing agents, *i.e.*, in presence of these ions, Pb<sup>4+</sup> ions are reduced to Pb<sup>2+</sup> ions.

$$Pb^{4+} + 2Br^{-} \longrightarrow Pb^{2+} + Br_{2}$$
  
 $Pb^{4+} + 2I^{-} \longrightarrow Pb^{2+} + I_{2}$ 

Except carbon halides, other halides are readily hydrolysed by water. The trend towards hydrolysis, however, decreases down the group. The hydrolysis is due to utilisation of d-orbitals to which water molecules can get attached.

The tetrahalides of Si, Ge, Sn and Pb can form hexahalo complexes like  $[SiF_6]^{2-}$ ,  $[GeF_6]^{2-}$ ,  $[GeCl_6]^{2-}$ ,  $[SnCl_6]^{2-}$  and  $[PbCl_6]^{2-}$  with the corresponding halide ions. Thus, tetrahalides of Si, Ge, Sn and Pb act as strong Lewis acids.

Carbon does not form dihalides. All the other elements do form dihalides. There is a steady increase in the stability of dihalides.

$$\operatorname{Si} X_2 < \operatorname{Ge} X_2 < \operatorname{Sn} X_2 < \operatorname{Pb} X_2$$

(iii) Oxides: All the elements of this group form oxides of the type  $MO_2$ .

The acidic nature decreases with increase of atomic number.  $CO_2$  and  $SiO_2$  are acidic while  $GeO_2$ ,  $SnO_2$  and  $PbO_2$  are amphoteric. All these dissolve in alkalies giving carbonates, silicates, germanates, stannates and plumbates, respectively.

$$MO_2 + 2NaOH \longrightarrow Na_2MO_3 + H_2O$$

The dioxides of Ge, Sn and Pb also dissolve in acids.

$$GeO_2 + 4HCl \longrightarrow GeCl_4 + 2H_2O$$
  
 $SnO_2 + 4HCl \longrightarrow SnCl_4 + 2H_2O$   
 $PbO_2 + 4HCl \longrightarrow PbCl_2 + Cl_2 + 2H_2O$ 

They also form oxides of the type MO. SiO is unstable. CO is neutral while SnO and PbO are amphoteric. Basic character of both mono and dioxide increases down the group.

# 9.2 COMPARISON OF CARBON AND SILICON

Carbon and silicon, the first two elements of group 14 have a number of similarities in their properties as both have same number of electrons in the outermost shell. They show many dissimilarities in properties also because the number of electrons in the penultimate shells are different.

#### Points of Similarities

(a) Electronic configuration: Both the elements have 4 electrons, *i.e.*,  $s^2p^2$  grouping in their valence shell.

**(b)** Occurrence: Both are widely distributed in nature. Carbon is the essential constituent of vegetable and animal

kingdom while silicon is an essential constituent of mineral kingdom.

- (c) Non-metallic: Both are typical non-metals. They form oxides of type  $MO_2$  which are acidic in nature. Their monoxides CO and SiO are neutral, SiO is comparatively unstable.
- (d) Valency: Both show tetravalency. Both form covalent compounds by sharing of electrons. Both show tetravalency on account of  $sp^3$  hybridization.
  - (e) Allotropy: Both show allotropy.
- (f) Catenation: Both carbon and silicon possess the property of catenation. Their atoms join with one another in large numbers forming the long chains and rings.
  - (g) Similar compounds:
- (i) Formation of oxides: Both burn in oxygen to form acidic oxides.

$$CO_2 + 2NaOH \longrightarrow Na_2CO_3 + H_2O$$
  
 $SiO_2 + 2NaOH \longrightarrow Na_2SiO_3 + H_2O$ 

(ii) Formation of hydrides: Both form a number of similar hydrides.

## Points of Difference (Dissimilarities)

#### Carbon

1. It has 2 electrons in the penultimate shell.

- 2. It is black solid. It does not melt.
- 3. Some allotropic forms of carbon, e.g., graphite are good conductors of electricity.
- 4. Caustic alkalies have no action on carbon.
- 5. The dioxide, carbon dioxide, is a gas. It has a linear structure. Carbon atom is linked to two oxygen atoms by double covalent bonds. Carbon is sp hybridized. These hybrid orbitals overlap with the porbital of each oxygen atom. The remaining 2p-orbital of each oxygen atom form π-bonds with p-orbitals of carbon atom.

$$O\frac{p-p}{\overline{p-sp}}C\frac{p-p}{\overline{sp-p}}O$$

 ${\rm CO_2}$  molecules are held together by weak van der Waals' forces hence it exists as a gas at ordinary temperatures.

Carbon dioxide dissolves in water and behaves as weak acid.

$$CO_2 + H_2O \rightleftharpoons H_2CO_3$$
Carbonic acid
 $2NaOH + CO_2 \longrightarrow Na_2CO_3 + H_2O$ 

- 6. The lower oxide, carbon monoxide, is known. It is stable and neutral in nature.
- It forms a large number of hydrides known as hydrocarbons which are stable. These are not hydrolysed by water.
- 8. It does not directly react with Cl2 or Br2.
- CCl<sub>4</sub> is a stable compound and it is not hydrolysed by water. The
  hydrolysis does not occur because water molecules cannot be
  coordinated to carbon as its maximum covalency is four.
- The oxyacid, H<sub>2</sub>CO<sub>3</sub>, is unstable. It is best known in the form of salts, carbonates.
- It does not form complex ions as d-orbitals are not present and maximum covalency is four.

$$\begin{array}{cccc} CH_4 & C_2H_6 & C_3H_8 & \cdot C_4H_{10} \\ SiH_4 & Si_2H_6 & Si_3H_8 & Si_4H_{10} \\ (Silane) & (Disilane) & (Trisilane) & (Tetrasilane) \end{array}$$

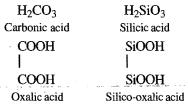

These are all colourless gases and burn in air to form oxides.

$$CH_4 + 2O_2 \longrightarrow CO_2 + 2H_2O$$
  
 $SiH_4 + 2O_2 \longrightarrow SiO_2 + 2H_2O$ 

(iii) Formation of halides: Both form covalent halides of same formula.

CCl <sub>4</sub>	CHCl <sub>3</sub>	$CF_4$
SiCl <sub>4</sub>	SiHCl <sub>3</sub>	SiF <sub>4</sub>

(iv) Formation of acids: Both form similar types of acids.

Silicon

It has 8 electrons in the penultimate shell.

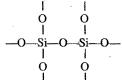

It is reddish brown solid. It melts at 1410°C.

It is bad conductor of heat and electricity.

It reacts with alkalies to evolve hydrogen.

$$Si + 2NaOH + H_2O \longrightarrow Na_2SiO_3 + 2H_2$$

The dioxide, silica, is a solid. It has a giant structure. The silicon atom is linked with oxygen atoms by single covalent bonds.

Silica has a three dimensional infinite structure in which silicon is tetrahedrally bonded to four oxygen atoms and each oxygen atom is bonded to two silicon atoms by covalent bonds. Hence, silica has high melting point and is a solid.

Silica is insoluble in water and acts as a very weak acid.

$$2NaOH + SiO_2 \longrightarrow Na_2SiO_3 + H_2O$$

The SiO is unstable.

It forms lesser number of hydrides which are not very stable. These act as reducing agents. These are hydrolysed by water with evolution of hydrogen.

It reacts with Cl2 or Br2 at 500°C.

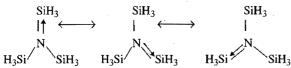

$$Si + 2Cl_2 \xrightarrow{500^{\circ}C} SiCl_4$$

SiCl<sub>4</sub> is less stable and it is hydrolysed by water. The hydrolysis is due to the fact that water molecules can be coordinated to Si as its maximum covalency is six.

The oxyacid,  $H_2SiO_3$ , is stable. It is also known in the form of salts, silicates.

It forms a number of complex ions as d-orbitals are present and maximum covalency is six.

(v) Structure of trimethyl ammonia and trisilyl ammonia: Trimethyl ammonia is pyramidal whereas trisilyl ammonia is a planar molecule. In silicon atom, there is vacant d-orbital hence electron pair of nitrogen is donated to silicon by  $p\pi - d\pi$  overlapping in trisilyl ammonia. Thus, trisilyl ammonia has planar structure.

Trimethyl ammonia has pyramidal shape due to presence of lone pair of electron at nitrogen.

### 9.3 COMPARISON OF TIN AND LEAD

Tin and lead are the last two members of group 14. Both resemble each other in many respects but lead being the last member having higher atomic mass differs in some respects with tin.

#### Points of Similarities

1. Electronic configuration: Both have same electronic configuration having 4 electrons in the outermost shell and 18 electrons in the penultimate shell.

**2. Metallic nature:** Both of them are metals. They have low melting and boiling points.

Element	m.pt. (°C)	b.pt. (°C)
Sn	232	2275
Pb	327	1620

Both are malleable in nature.

- 3. Valency: Both show valency of 4 and 2 in their compounds. It is based on the fact that either 4 or 2 electrons from the outermost shell act as valency electrons. The lower valency, i.e., 2 is shown on account of the inertness of ns pair of electrons. The compounds having divalency are electrovalent while compounds having tetravalency show covalent nature. Both are electropositive metals but also exhibit an electronegative character in some of their compounds. Similar to silicates, the stannates and plumbates are known.
- **4. Action of alkalies:** Both react with hot alkali solutions and liberate hydrogen.

$$Sn + 2NaOH + H_2O \longrightarrow Na_2SnO_3 + 2H_2$$
  
 $Pb + 2NaOH + H_2O \longrightarrow Na_2PbO_3 + 2H_2$ 

5. Both form amphoteric oxides of the type MO and  $MO_2$ .

$$SnO + 2NaOH \longrightarrow Na_2SnO_2 + H_2O$$

$$(Sodium stannite)$$

$$SnO + H_2SO_4 \longrightarrow SnSO_4 + H_2O$$

$$PbO + 2NaOH \longrightarrow Na_2PbO_2 + H_2O$$

$$(Sodium plumbite)$$

$$PbO + H_2SO_4 \longrightarrow PbSO_4 + H_2O$$

**6.** Both form tetrachlorides of the type  $MCl_4$ . These are hydrolysed by water.

$$SnCl_4 + 4H_2O \longrightarrow Sn(OH)_4 + 4HCl$$
  
 $PbCl_4 + 2H_2O \longrightarrow PbO_2 + 4HCl$ 

These tetrachlorides combine with HCl to form chloro acids.

H<sub>2</sub>PbCl<sub>6</sub>

Lead

 $Pb + S \longrightarrow PbS$ 

Lead does not show allotropy.

$$\begin{array}{ccc} & & & & & & \\ \text{Chlorostannic acid} & & & & & \\ \text{Tetrachlorides decompose on heating.} & & & & \\ & & & & & \\ \text{SnCl}_4 & \longrightarrow & \text{SnCl}_2 + \text{Cl}_2 \\ \end{array}$$

H<sub>2</sub>SnCl<sub>6</sub>

PbCl<sub>4</sub>  $\longrightarrow$  PbCl<sub>2</sub> + Cl<sub>2</sub>
7. Sulphides of both are precipitated by passing H<sub>2</sub>S through their salt solutions.

$$\begin{array}{c} PbCl_2 \, + \, H_2S \longrightarrow PbS \, + \, 2HCl \\ Black \ ppt. \end{array}$$
 
$$SnCl_2 \, + \, H_2S \longrightarrow SnS \quad + \, 2HCl \\ Yellow \ ppt. \end{array}$$

- 8. Both form tetrahydrides which are unstable.
- 9. Both form organometallic compounds.

Tin

 $Sn + 2S \longrightarrow SnS_2$ 

1. Tin shows allotropy.

 $Sn(C_2H_5)_4$   $Pb(C_2H_5)_4$  Lead tetraethyl

## 9.4 CARBON

## 1. Unique properties of carbon in the group

- 1. Carbon has the smallest atomic radius and lowest atomic volume amongst all the elements of group 14.
- 2. It is most compact. It is the hardest and has highest melting and boiling points amongst the elements of group 14.
- 3. It has the highest ionisation energy and is most electronegative element of group 14.
- 4. Its maximum covalency is 4 as d electrons are absent in the valency shell.
- 5. It has maximum property of catenation. It can form multiple bonds. As a result, carbon forms a large number of compounds.
- 6. Carbon dioxide, CO<sub>2</sub>, is a gas while the dioxides of other elements are solids.
- 7.  $CCl_4$  does not undergo hydrolysis while the tetrahalides,  $MX_4$ , of other elements undergo hydrolysis.

#### 2. Occurrence

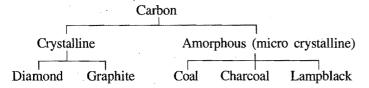

Carbon is one of the most widely distributed elements in nature. It occurs free as well as in the combined state. It occurs free in crystalline form as diamond, graphite, and in the amorphous form as coal. It is present in all living organisms, plants and animals, in the combined state in the form of proteins, carbohydrates, fats and other complicated compounds. It is present as hydrocarbons in natural gas and petroleum. It occurs as carbon dioxide and carbon monoxide in atmosphere. In mineral world, it occurs in the form of carbonates such as limestone, CaCO<sub>3</sub>; magnesite, MgCO<sub>3</sub>; calamine, ZnCO<sub>3</sub>; dolomite, MgCO<sub>3</sub>·CaCO<sub>3</sub>; siderite, FeCO<sub>3</sub>; cerussite, PbCO<sub>3</sub>; etc.

## 3. Allotropic forms of carbon

The property due to which an element exists in two or more forms which differ in their physical and some of the chemical properties is known as allotropy and the various forms are called allotropes or allotropic modifications. This phenomenon is due to the difference either in the number of atoms in the molecules [as in the case of oxygen (O<sub>2</sub>) and ozone (O<sub>3</sub>)] or arrangement of atoms in the molecules (as in the case of various forms of carbon).

Carbon exists in two allotropic forms:

(a) Crystalline and (b) amorphous. The crystalline forms are diamond and graphite while the amorphous forms are coal, charcoal, lampblack, etc.

- (a) Diamond: (i) It is the purest form of carbon.
- (ii) It is found naturally as well as obtained artificially.
- (iii) It is the hardest natural substance known.
- (iv) It is transparent and has a specific gravity 3.52.
- (v) It is a bad conductor of heat and electricity. It is transparent to X-rays and glows in ultraviolet rays with bluish green colour.
- (vi) Its refractive index is high (2.45) and when properly cut, it produces maximum total internal reflection which is responsible for its brilliance.
- (vii) It is chemically inert. It is not attacked by acids, alkalies and salts. It burns in air on heating at  $900^{\circ}$ C to form  $CO_2$ . It reacts with fluorine at  $700^{\circ}$ C to form  $CF_4$ .

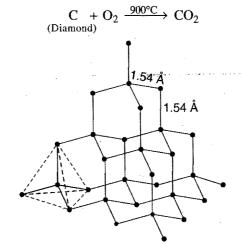

Fig. 9.1 Structure of diamond

$$C + 2F_2 \xrightarrow{700^{\circ}C} CF_4$$

The important properties of diamond are related to its structure. In diamond, each carbon atom is in  $sp^3$  hybridized state and linked to four other carbon atoms tetrahedrally by covalent bonds. This gives a giant three dimensional polymeric structure in which C—C distance is 1.54 Å and bond angle is  $109.5^{\circ}$ .

As the atoms are held firmly by strong covalent bonds, diamond is the **hardest substance**, possesses very high melting point (3600°C) and chemically inert. Since there is no mobile electron present, diamond is non-conductor of electricity.

Uses: Diamond is used as a gem stone on account of reflection and refraction of light. Impure diamonds (black) are used in knives for cutting glass, "Diamond studded saws" in drill bits, as rock borers and is also used as polishers.

**(b) Graphite:** (i) It is found in nature and also manufactured by Acheson process. Anthracite is heated with sand in an electric furnace of the resistance type. It is fitted with two carbon electrodes joined by a thin carbon rod through which an alternating current is passed (Fig. 9.2).

The charge is heated at 3000°C for 24–30 hours. Silicon carbide is formed first which decomposes at high temperature into graphite and silicon. Silicon volatilizes away leaving behind graphite.

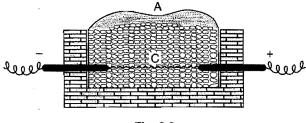

Fig. 9.2

$$SiO_2 + 3C \longrightarrow SiC + 2CO$$

$$\downarrow \qquad \qquad C + Si$$
(Graphite)

- (ii) It is a soft, greasy, dark greyish coloured crystalline solid.
  - (iii) Its density is 2.5 g mL<sup>-1</sup>.
- (iv) It is good conductor of electricity and its conductivity increases with temperature.
- (v) It leaves a black mark on paper and is called **black lead** or **plumbago.**
- (vi) It is chemically more active than diamond. It ignites in air or oxygen at  $700^{\circ}$ C to form  $CO_2$ . It is not attacked by alkalies and dilute acids. However, when treated with concentrated HNO<sub>3</sub> or concentrated H<sub>2</sub>SO<sub>4</sub>, it is oxidised to insoluble yellowish green substance known as graphitic acid,  $C_{11}H_4O_5$ . With alkaline potassium permanganate, it is oxidised to mellitic acid  $[C_6(COOH)_6]$  and oxalic acid. It forms  $CO_2$  with chromic acid.

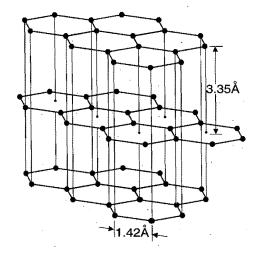

Fig. 9.3 Structure of graphite

It has a two dimensional sheet structure. Each carbon atom is in  $sp^2$  hybridized state and is linked to three other carbon atoms in a hexagonal planar structure. As there are four valence electrons in each carbon atom, after forming three C—C bonds, each carbon atom is left with one spare electron in its p-orbital. This electron then overlaps with each other to form a  $\pi$ -bond. Hence, the C—C distance in graphite is shorter (1.42 Å) than that of diamond (1.54 Å). The  $\pi$ -electrons are

free to move throughout the entire layers, graphite is good conductor of electricity. The adjacent layers are held by weak van der Waals' forces and the distance between two layers is sufficiently large (3.4 Å). Thus, two adjacent layers can easily slide over each other and hence graphite is soft and possesses low density. The more reactivity of graphite is due to the presence of mobile electrons. Graphite is of two forms:  $\alpha$  and  $\beta$ .

In  $\alpha$ -graphite layers are arranged in sequence ABAB, with the third layer exactly above first layer. In  $\beta$ -graphite, the layers are arranged as ABCABC........ The two forms are interconvertible.

Graphite is thermodynamically more stable than diamond and its free energy of formation is 1.9 kJ less than diamond.

Graphite 
$$\frac{1600^{\circ}\text{C}}{50000-60000 \text{ atm.}}$$
 Diamond

When graphite is heated with vapours of K, Rb, Cs at  $300^{\circ}$ C, it forms  $C_8M$ . Graphite is diamagnetic but  $C_8M$  is paramagnetic.

**Uses:** Graphite is used:

- (i) for lining and making electrodes of electric furnaces.
- (ii) in making refractory crucibles.
- (iii) in making lead pencils.
- (iv) as a moderator in nuclear reactor.
- (v) as a lubricant in machinery.
- (c) Coal: It is the crude form of carbon. It has been formed in nature as a result of slow decomposition of vegetable matter under the influence of heat, pressure and limited supply of air. It is found in various forms which represent the different stages of transformation of vegetable matter. The successive stages of transformation are: peat, lignite, bituminous, steam coal and anthracite. The carbon contents of these forms along with calorific values are given below:

	Peat	Lignite	Bituminous	Steam coal	Anthracite
Carbon content %.	60	67	88	93	95
Calorific value	.9900	11,700	14,950	15,720	16,200
(B.Th.U. per 1b)			· ·		

[1 B.Th.U. = 252 calories or 397 B.Th.U. = 1 kcal.]

The common variety of coal is bituminous. It is hard like stone and burns with smoky flame. The superior quality is anthracite which burns with non-smoky flame.

When coal is subjected to destructive distillation by heating in the absence of air, it loses volatile constituents such as coal gas, ammonia, benzene, phenol and tar, the residue left behind is coke. Thus, coke is an artificial product. It is coal minus volatile matter.

**Uses:** Coal is mainly used: (i) as a fuel. (ii) for the manufacture of coal gas, coal tar and coke. (iii) in the manufacture of synthetic petrol.

Coke is used: (i) as a reducing agent in iron and steel industry. (ii) as a fuel. (It burns without smoke) (iii) for making fuel gases and graphite.

(d) Charcoal: This form of carbon is obtained by burning wood, cellulose or any other carbonous matter in a limited supply of air. Charcoal is of various forms such as wood charcoal, sugar charcoal, coconut charcoal, animal charcoal, etc. These forms contain varying amounts of carbon content. A very pure form of carbon is obtained from sugar. Wood charcoal is porous and has a very large surface area per unit weight. It is, therefore, used as an adsorbent. When charcoal is given a special treatment in order to increase its absorption capacity, the resulting material is known as activated charcoal and the process of treatment is called activation. Activation is carried out by heating the charcoal in retorts at 800-850°C in a current of superheated steam. This removes the impurities sticking on the surface and blocking the capillary pores.

Charcoal is the most active form of carbon. It easily burns in air to form  $CO_2$ . It reacts with many oxidising agents. It is affected by conc.  $HNO_3$  and conc.  $H_2SO_4$ .

$$C + 4HNO_3 \longrightarrow CO_2 + 4NO_2 + 2H_2O$$
  
 $C + 2H_2SO_4 \longrightarrow CO_2 + 2SO_2 + 2H_2O$ 

Uses: Charcoal is used:

- (i) in removing offensive odour from air in the airconditioning processes.
- (ii) in making filters in cigarettes as to remove vapours of nicotine.
  - (iii) in removing fused oil from crude spirit.
- (iv) in decolourising sugar syrup and refining oils, fats, glycerine, etc.
- (v) in treatment of drinking water after chlorination as it adsorbs excess of chlorine.
  - (vi) in gas masks as it adsorbs poisonous gases.
- **(e)** Lampblack or carbon black or soot: It is obtained by burning substances rich in carbon content such as kerosene, petroleum, turpentine oil, acetylene, etc., in a limited supply of air. These substances yield a large amount of smoke which is passed into chambers having wet blankets. The soot collected on these blankets is called lampblack.

It is almost pure carbon. The carbon content is as high as 98–99% with a small impurity of hydrocarbon. Lampblack is a soft black powder. It is used for making printing inks, black paints, Indian ink, boot polishes and ribbons of typewriters. The main application, at present, is as a filler in making rubber tyres.

## **4. Fullerenes or Bucky balls**

Chemistry is full of surprises and the discovery of a new series of allotropes of carbon must rank as one of the most unexpected findings of all.

Fullerenes constitute a family of structures in which carbon atoms are arranged in a spherical or elliptical structure. To make such a structure, the carbon atoms form five or six-membered rings, similar to the pattern of lines on a soccer ball. One of the most interesting carbon molecules, made in 1985, as a result of action of a laser beam on a sample of graphite

is  $C_{60}$ . It was given the name of **buckminster fullerene**. It is made from interlocking hexagonal and pentagonal rings of carbon atoms. The  $C_{60}$  molecule structure is shown in Fig. 9.4. Such molecules are now thought to exist even in chimney soot or candle soot. Each carbon is  $sp^2$  hybridised. The average  $\dot{C}$ —C distance is 144 pm.

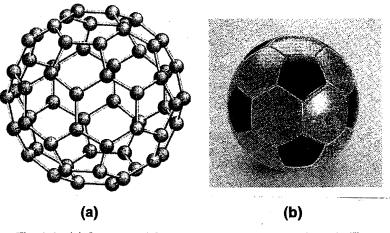

Fig. 9.4 (a) Structure of C<sub>60</sub>, buckminsterfullerene a "buckyball"
 (b) The buckminsterfullerene molecule is often called "buckyball" because of its football appearance

Another molecule  $C_{70}$  has been recently discovered. These and similar large carbon molecules are sometimes referred as **bucky balls.** This allotrope family was named after R. Buckminster Fuller, a genius architect of the twentieth century.

One method of manufacturing the fullerenes is to use an intense laser beam to heat graphite to temperatures of over 10,000°C. At these temperatures, sections of the hexagonal planes of carbon atoms peel off the surface and wrap themselves into balls.

Diamond and graphite are insoluble in all solvents but fullerenes are highly soluble in nonpolar solvents such as hexane and toluene. Although black in solid phase, fullerenes display a wide range of colours in solution. All the fullerenes sublime when heated. The  $C_{60}$  molecules pack together in the same way as metal atoms do, forming a face centred cubic arrangement. The fullerenes have low densities (about 1.5 g cm<sup>-3</sup>) and they are non-conductors of electricity. All the carbon atoms in buckminster fullerene are  $sp^2$  hybridized because all carbon atoms are equivalent, the strain caused by distortion of the bonds from coplanarity is equally distributed among all the carbon atoms. Thus, this molecule is quite stable.

The fullerenes are easily reduced to anions by reaction with alkali and alkaline earth metals. For example, rubidium fits within the interstices in the  $C_{60}$  lattice to give  $Rb_3C_{60}$ . This compound is a super conductor at temperatures below 28K. Chemical reaction with the surface of the fullerenes is also possible; thus reaction with fluorine results in the formation of  $C_{60}F_{60}$ .

Besides  $C_{60}$  and  $C_{70}$ , even-numbered fullerenes from  $C_{70}$  to  $C_{100}$  are known. Only recently, a fullerene  $C_{36}$  has been established. It is a black solid and gives a golden-yellow solution.

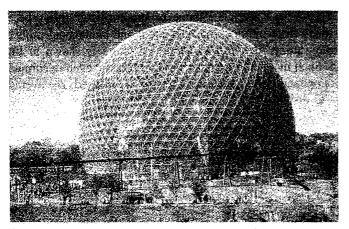

Fig. 9.5 The American Pavilion at the Montréal Expo in 1967 was geodesic dome designed by R. Buckminster Fuller. The dome is a three-quarter sphere, 200 feet high and 250 feet in diameter.

## 5. Chemical properties of carbon

Charcoal has the enormous surface area and hence, it is the most reactive form of carbon. The other forms such as diamond, graphite, coal, etc., which are denser, are less reactive in nature.

(a) Combustion: All the allotropic forms of carbon burn in air or oxygen forming carbon dioxide (when oxygen supply is sufficient) and carbon monoxide (when oxygen supply is insufficient).

$$C + O_2 \longrightarrow CO_2$$
 (Carbon dioxide)  
 $2C + O_2 \longrightarrow 2CO$  (Carbon monoxide)

This property shows that all the allotropic forms are chemically identical.

**(b) Reducing agent:** Carbon is a strong reducing agent. It reduces many metallic oxides to corresponding metals, sulphates into sulphides and water to hydrogen. These reactions occur at high temperatures.

$$ZnO + C \longrightarrow Zn + CO$$
 $PbO + C \longrightarrow Pb + CO$ 
 $PbSO_4 + 4C \longrightarrow PbS + 4CO$ 
 $BaSO_4 + 4C \longrightarrow BaS + 4CO$ 
 $C + H_2O \xrightarrow{Red hot} CO + H_2$ 

(c) Combination with other elements: It combines with sulphur when the vapours of sulphur are passed over red hot carbon forming carbon disulphide.

$$C + 2S \longrightarrow CS_2$$

When electric arc is struck between carbon electrodes in presence of hydrogen, acetylene is formed.

$$2C + H_2 \longrightarrow C_2H_2$$

Beryllium when heated with carbon forms carbide

$$2\text{Be} + \text{C} \longrightarrow \text{Be}_2\text{C}$$

Various carbides are formed when carbon is heated with certain oxides.

$$CaO + 3C \xrightarrow{2000^{\circ}C} CaC_2 + CO$$

$$Calcium \ carbide$$

$$SiO_2 + 3C \xrightarrow{2000^{\circ}C} SiC + 2CO$$

$$Silica \qquad Carborundum$$

$$2Al_2O_3 + 9C \xrightarrow{2000^{\circ}C} Al_4C_3 + 6CO$$

(d) Reactivity towards acids: Charcoal dissolves slowly in hot dilute HNO<sub>3</sub> forming a brown coloured substance, artificial tannin. Conc. HNO<sub>3</sub> oxidises carbon to carbon dioxide.

$$C + 4HNO_3 \longrightarrow CO_2 + 4NO_2 + 2H_2O$$

Hot and conc. H<sub>2</sub>SO<sub>4</sub> also oxidises it to carbon dioxide. A small quantity of mellitic acid (benzene hexacarboxylic acid) is also formed.

$$C + 2H_2SO_4 \longrightarrow CO_2 + 2SO_2 + 2H_2O$$
  
 $12C + 9H_2SO_4 \longrightarrow C_6(COOH)_6 + 6H_2O + 9SO_2$ 

## 9.5 COMPOUNDS OF CARBON

#### 1. Oxides of Carbon

Two oxides of carbon, carbon monoxide and carbon dioxide are important and described below:

## (a) Carbon Monoxide, CO

It is found in small amounts in volcanic gases, chimney gases, exhaust gases of internal combustion engines and coal gas.

**Preparation:** The following methods can be applied for the preparation of carbon monoxide:

(i) By heating oxalic acid with concentrated sulphuric acid: A mixture of CO and CO<sub>2</sub> is obtained. Sulphuric acid acts as a dehydrating agent. CO<sub>2</sub> is removed by passing the gaseous mixture through caustic soda or caustic potash solution.

$$\begin{array}{c|c} \text{COOH} & \xrightarrow{\text{H}_2\text{SO}_4} & \text{CO} + \text{CO}_2 \\ \hline \text{COOH} & \xrightarrow{\text{-H}_2\text{O}} & \text{CO} + \text{CO}_2 \end{array}$$

Similarly by heating formic acid with concentrated H<sub>2</sub>SO<sub>4</sub>, only CO is obtained.

$$\text{HCOOH} \xrightarrow{\text{H}_2\text{SO}_4} \text{CO}$$

(ii) By the reduction of oxides of heavy metals with carbon: On heating oxides of heavy metals with carbon, CO is formed.

$$Fe_2O_3 + 3C \longrightarrow 2Fe + 3CO$$
  
 $ZnO + C \longrightarrow Zn + CO$ 

(iii) By reduction of carbon dioxide:  $CO_2$  can be reduced with carbon or zinc at high temperatures.  $CO_2$  when passed over red hot zinc, a mixture of CO and  $CO_2$  is obtained.

$$Zn + CO_2 \xrightarrow{Heat} ZnO + CO$$

Similarly, when  $CO_2$  is passed over red hot charcoal, the reduction of  $CO_2$  into CO occurs with the formation of a mixture of  $CO_2$  and CO. The gaseous mixture is passed through NaOH or KOH solution as to remove  $CO_2$ .

(iv) By heating carbonates of calcium, barium or magnesium with zinc, CO is obtained.

$$MgCO_3 + Zn \longrightarrow MgO + ZnO + CO$$

(v) By heating potassium ferrocyanide with conc.  $H_2SO_4$ : When potassium ferrocyanide in powdered state is heated with concentrated  $H_2SO_4$ , CO is evolved. Dilute  $H_2SO_4$  should never be used because it shall evolve highly poisonous gas, HCN.

$$K_4Fe(CN)_6 + 3H_2SO_4 \longrightarrow 2K_2SO_4 + FeSO_4 + 6HCN$$
  
 $6HCN + 12H_2O \longrightarrow 6HCOOH + 6NH_3$   
 $Formic acid$   
 $6NH_3 + 3H_2SO_4 \longrightarrow 3(NH_4)_2SO_4$   
 $6HCOOH \xrightarrow{H_2SO_4} 6CO + 6H_2O$ 

$$K_4Fe(CN)_6 + 6H_2SO_4 + 6H_2O \longrightarrow 2K_2SO_4 + FeSO_4 + 6CO + 3(NH_4)_2SO_4$$

**Manufacture:** Carbon monoxide is obtained in the form of water gas and producer gas when air (moist) is passed over a bed of white hot coke. The following reactions may occur.

$$2C + O_2 \longrightarrow 2CO$$

$$C + O_2 \longrightarrow CO_2$$

$$C + H_2O \longrightarrow \underbrace{CO + H_2}_{Water gas}$$

Carbon dioxide is reduced by passing the mixture over heated charcoal.

$$CO_2 + C \longrightarrow 2CO$$

The CO produced, always consists of  $N_2$ ,  $H_2$ ,  $CO_2$ , etc. **Properties:** (i) It is a colourless and odourless gas.

- (ii) It is slightly soluble in water.
- (iii) It is a combustible gas but does not support combustion.
- (iv) Its density is nearly equal to the density of air.
- (v) It is highly poisonous in nature. One part in 100 parts of air causes death in few minutes. The poisonous nature of CO is due to the fact that it combines with haemoglobin (a red colouring matter of blood which is absorber of oxygen) to form **carboxy-haemoglobin** which is not a able to absorb oxygen and as a result of this, suffocation and as place. This phenomenon is known as ASPHYXIA.
  - (vi) It is not decomposed by heat.

- (vii) It is neutral to litmus.
- (viii) It burns with blue flame to form CO<sub>2</sub>. This is an exothermic process.

$$2CO + O_2 \longrightarrow 2CO_2 + Heat$$

(ix) It is a good reducing agent as it takes up oxygen and converted into CO<sub>2</sub>. This property is utilised for the extraction of metals from their oxides.

$$Fe_2O_3 + 3CO \xrightarrow{600-900^{\circ}C} 2Fe + 3CO_2$$

$$ZnO + CO \longrightarrow Zn + CO_2$$

$$PbO + CO \longrightarrow Pb + CO_2$$

It reduces Fehling's solution also.

$$2Cu(OH)_2 + CO \longrightarrow Cu_2O + 2H_2O + CO_2$$

It reduces  $I_2O_5$  into iodine.

$$I_2O_5 + 5CO \longrightarrow I_2 + 5CO_2$$

(x) The bonding in carbon monoxide is represented as,

Thus, all the four valencies of carbon are not satisfied. It behaves as unsaturated compound and forms addition products with a number of substances.

$$\begin{array}{c} \text{CO} + 2\text{H}_2 \xrightarrow{\hspace{0.2cm} 150-400^{\circ}\text{C}} & \text{CH}_3\text{OH} \\ \text{Methyl alcohol} \\ \text{CO} + \text{Cl}_2 \xrightarrow{\hspace{0.2cm} \text{Sunlight} \\ \text{or camphor}} & \text{COCl}_2 \\ \text{Phosgene} \\ \\ \text{CO} + \text{S} \xrightarrow{\hspace{0.2cm} \text{Heat}} & \text{COS} \\ \text{Carbonyl sulphide} \\ \text{CO} + \text{NaOH} \xrightarrow{\hspace{0.2cm} \text{Under} \\ \text{pressure}} & \text{HCOONa} \\ \text{Sodium formate} \\ \\ \text{CuCl} + \text{CO} \xrightarrow{\hspace{0.2cm} \text{High} \\ \text{pressure}} & \text{CuCl} \cdot \text{CO} \\ \text{Addition} \\ \text{soln.)} & \text{product} \\ \end{array}$$

It combines with metals like Cr, Ni, Fe, etc. The compounds thus formed are called carbonyls.

Ni + 4CO 
$$\xrightarrow{80^{\circ}\text{C}}$$
 Ni(CO)<sub>4</sub>  
Fe + 5CO  $\xrightarrow{180^{\circ}\text{C}}$  Fe(CO)<sub>5</sub>

These reactions are used in the extraction and purification of metals.

**Uses:** (i) It is used as a fuel in the form of water gas  $(CO + H_2)$  and producer gas  $(CO + N_2)$ .

- (ii) CO is used in the manufacture of methanol, synthetic petrol, formic acid and phosgene gas (highly poisonous gas).
  - (iii) It is used as a reducing agent in the extraction of iron.
  - (iv) It is used in the extraction of nickel (Mond's process).

**Structure:** The electronic structure of carbon monoxide may be represented as follows:

$$:\bar{c}:::\bar{o}: \text{ or } :\bar{c}=\bar{o}: \text{ or } :c \subseteq o$$

Carbon atom is sp hybridized. One sp-orbital is being used to form a single bond with oxygen atom while the other sp-orbital which points away from the C—O bond contains a lone pair of electrons. The remaining two unhybridized p-orbitals form two  $\pi$ -bonds with two p-orbitals of oxygen atoms. The presence of a triple bond is evidenced by the following facts:

- (i) The bond length between carbon and oxygen is 1.13 Å which corresponds to carbon-oxygen triple bond.
  - (ii) The value of dipole moment is small.
- (iii) Due to presence of lone pair of electrons on carbon, carbon monoxide molecule acts as a ligand and can form a coordinate bond with certain metals  $(M \leftarrow C \stackrel{\leftarrow}{=} O)$ .

## (b) Carbon Dioxide, CO<sub>2</sub>

**Occurrence:** It is present in atmosphere to the extent of 0.03–0.05 per cent. It comes to the atmosphere from animal breathing, decay of vegetable matter, burning of carbon and carbonous matter, etc. It is also utilised by plants in photosynthesis. Thus, a carbon dioxide cycle is operating in nature and the proportion of  $CO_2$  in the atmosphere remains about the same. It is found in combined state in the form of carbonates.

**Preparation:** The following methods are used for its preparation:

(i) By the complete combustion of carbon: Carbon is burnt in free supply of air.

$$C + O_2 \longrightarrow CO_2$$

If CO is formed, it also burns with pale blue flame forming carbon dioxide.

$$2C + O_2 \longrightarrow 2CO$$
$$2CO + O_2 \longrightarrow 2CO_2$$

(ii) By the action of dil. mineral acids on carbonates and bicarbonates: Mineral acids react with carbonates and bicarbonates and evolve carbon dioxide.

$$CaCO_3 + 2HCl \longrightarrow CaCl_2 + H_2O + CO_2$$
  
 $Na_2CO_3 + 2HCl \longrightarrow 2NaCl + H_2O + CO_2$   
 $NaHCO_3 + HCl \longrightarrow NaCl + H_2O + CO_2$ 

This method is used in the laboratory for the formation of carbon dioxide. Marble pieces ( $CaCO_3$ ) are taken in Woulfebottle which is fitted with a thistle funnel and a delivery tube. The other end of the delivery tube is kept into a dry cylinder through a card board disc. Pieces of marble are first covered with water and then concentrated HCl is added through the funnel.  $CO_2$  is formed which is collected by upward displacement of air.

Sulphuric acid is not used for the preparation because calcium sulphate formed gets deposited on the pieces of marble. This prevents the further action of  $H_2SO_4$  on marble pieces.

(iii) By heating carbonates and bicarbonates: The carbonates of less electropositive metals on heating decompose evolving carbon dioxide.

$$ZnCO_3 \longrightarrow ZnO + CO_2$$
  
 $CuCO_3 \longrightarrow CuO + CO_2$ 

Bicarbonates of all the metals decompose on heating with evolution of CO<sub>2</sub>.

$$2NaHCO_3 \longrightarrow Na_2CO_3 + H_2O + CO_2$$
  
 $Ca(HCO_3)_2 \longrightarrow CaCO_3 + H_2O + CO_2$ 

**Manufacture:** (i) From fuel gases: The fuel gases produced during the combustion of coal or coke contain large amounts of carbon dioxide mixed with nitrogen, carbon monoxide, oxygen, etc. These gases are passed through  $K_2CO_3$  solution which absorbs  $CO_2$ .

$$K_2CO_3 + CO_2 + H_2O \longrightarrow 2KHCO_3$$

This solution is then boiled when CO<sub>2</sub> is liberated.

$$2KHCO_3 \longrightarrow K_2CO_3 + H_2O + CO_2$$

(ii) From lime kilns: When lime is manufactured by the calcination of lime stone, (CaCO<sub>3</sub>), carbon dioxide is obtained as a by-product.

$$CaCO_3 \longrightarrow CaO + CO_2$$

(iii) From fermentation: During fermentation; when molasses are changed into alcohol, a large amount of CO<sub>2</sub> is obtained as a by-product.

$$\underset{Glucose}{Sugar} \longrightarrow \underset{Glucose}{C_6H_{12}O_6} \longrightarrow 2C_2H_5OH + 2CO_2$$

**Properties:** (i) It is a colourless, odourless and tasteless gas.

- (ii) It is slightly soluble in water under ordinary pressure but at high pressures, the solubility is high.
  - (iii) It is heavier than air.
- (iv) It is easily liquefied under pressure into a colourless mobile liquid. If CO<sub>2</sub> under pressure is allowed to escape through a nozzle, a white solid, *i.e.*, **dry ice** is obtained. Solid CO<sub>2</sub> is a soft, white, snow like substance. It sublimes and leaves no residue. Solid CO<sub>2</sub> is used as a refrigerant under the commercial name **drikold**. It is used in the transport of perishable food materials. It provides cold as well as the inert atmosphere which helps in killing the undesirable bacteria.
- (v) It is neither combustible nor a supporter of combustion. However, burning magnesium, sodium or potassium continues burning in the gas.

$$CO_2 + 2Mg \longrightarrow 2MgO + C$$

$$CO_2 + 4Na \longrightarrow 2Na_2O + C$$

$$\downarrow^{CO_2}$$

$$Na_2CO_3$$

[Note: CO<sub>2</sub> is used as fire extinguisher but it cannot be used in the case of active metal fires which have affinity for oxygen.]

(vi) CO<sub>2</sub> acts as an oxidising agent. When heated with Zn, iron or carbon, these are oxidised.

$$Zn + CO_2 \longrightarrow ZnO + CO$$
  
 $CO_2 + C \longrightarrow 2CO$ 

(vii) CO<sub>2</sub> is an acidic oxide. It dissolves in water forming unstable carbonic acid.

$$H_2O + CO_2 \Longrightarrow H_2CO_3$$

It combines with alkalies to form two series of salts, carbonates and bicarbonates.

$$2NaOH + CO_2 \longrightarrow Na_2CO_3 + H_2O$$

With excess of CO<sub>2</sub>, carbonate is converted into bicarbonate.

$$Na_2CO_3 + H_2O + CO_2 \longrightarrow 2NaHCO_3$$

Lime water, Ca(OH)<sub>2</sub>, is turned milky on passing CO<sub>2</sub> with the formation of insoluble calcium carbonate.

$$Ca(OH)_2 + CO_2 \longrightarrow CaCO_3 + H_2O$$
Insoluble

The milkiness disappears on passing more of CO<sub>2</sub> with the conversion of calcium carbonate into soluble calcium bicarbonate.

$$CaCO_3 + H_2O + CO_2 \longrightarrow Ca(HCO_3)_2$$
Soluble

(viii) CO<sub>2</sub> reacts with basic oxides like Na<sub>2</sub>O, K<sub>2</sub>O, etc.,to form corresponding carbonates.

$$K_2O + CO_2 \longrightarrow K_2CO_3$$
  
 $Na_2O + CO_2 \longrightarrow Na_2CO_3$ 

(ix) CO<sub>2</sub> is converted by plants in the presence of sunlight and chlorophyll into glucose and higher carbohydrates. This process is known as photosynthesis.

$$6CO_2 + 6H_2O \longrightarrow C_6H_{12}O_6 + 6O_2$$

Uses: (i) It is used in the manufacture of aerated water.

- (ii) Solid  $\rm CO_2$  (dry ice) is used in refrigeration. It is superior refrigerant than common ice because it can produce very low temperatures and does not form liquid on melting. A mixture of solid  $\rm CO_2$  and ether is used to produce low temperature of the order of  $-80^{\circ}\rm C$  to  $-100^{\circ}\rm C$ .
- (iii) Carbogen is a mixture of  $O_2$  and  $CO_2$  (5–10%). It is used for artificial respiration in the case of pneumonia patients and victims of CO poisoning.
- (iv) It is used in the manufacture of white lead and sodium carbonate (Solvay process).
- (v) CO<sub>2</sub> is used as fire extinguisher. The use of common fire extinguisher is based on the production of CO<sub>2</sub>. A soda acid fire extinguisher contains a concentrated solution of sodium bicarbonate and a bottle containing concentrated sulphuric acid. When the apparatus is turned upside down the acid flows out of the bottle and reacts with sodium bicarbonate to produce CO<sub>2</sub>.

Aluminium sulphate in place of conc. $H_2SO_4$  is used in foam type fire extinguishers. When solution of NaHCO<sub>3</sub> and aluminium sulphate react,  $CO_2$  is liberated along with the hydrolysis of aluminium sulphate producing aluminium hydroxide in the form of foam.

$$Al_2(SO_4)_3 + 6NaHCO_3 \longrightarrow 2Al(OH)_3 + 3Na_2SO_4 + 6CO_2$$
  
 $Al_2(SO_4)_3 + 6H_2O \longrightarrow 2Al(OH)_3 + 3H_2SO_4$ 

Al(OH)<sub>3</sub> deposits on the burning articles and thus cuts off their contact with the air.

(vi) CO<sub>2</sub> is used by plants in the form of food.

**Structure:** CO<sub>2</sub> has a linear structure since its dipole moment is zero. Both the oxygen atoms are linked by double bonds.

$$O = C = O$$

The C—O bond length is 1.15 Å which is less than calculated value of double bond C—O. Thus, it is believed that CO<sub>2</sub> molecule is a resonance hybrid of the following structures:

$$0=C=0 \longleftrightarrow \overset{+}{0}=C-\overset{-}{0} \longleftrightarrow \overset{-}{0}-C=\overset{+}{0}$$

The formation of the molecule can be explained on the basis of hybridization. Carbon is sp- hybridized. The hybrid orbitals form sigma bonds with p-orbitals of each oxygen atoms. The unhybridized two p-orbitals of carbon atom form two  $\pi$ -bonds with two oxygen atoms.

Carbon forms some less stable oxides, e.g.,  $C_3O_2$ ,  $C_5O_2$  and  $C_1O_2O_3$ . Graphite oxides are  $C_2O_3$  and  $C_2O_3$  which are still less stable. Carbon suboxide is formed by dehydration of malonic acid.

$$CH_2 \stackrel{COOH}{\underbrace{\qquad \qquad \qquad \qquad \qquad \qquad }} O=C=C=C=O+2H_2O$$

Some important reactions of carbon suboxide are:

$$C_{3}O_{2} + 2H_{2}O \longrightarrow CH_{2}$$

$$COOH$$

$$Malonic acid$$

$$COCI$$

$$C_{3}O_{2} + 2HCI \longrightarrow CH_{2}$$

$$COCI$$

$$Malonyl chloride$$

$$C_{3}O_{2} + 2NH_{3} \longrightarrow CH_{2}$$

$$CONH_{2}$$

$$CONH_{2}$$

$$Malonyl amide$$

# 2. Carbonic Acid, Carbonates and Bicarbonates

Carbon dioxide is an acidic oxide. The solution of CO<sub>2</sub> in water shows feeble acidic nature. This is believed due to the formation of carbonic acid.

 $CO_2 + H_2O \Longrightarrow H_2CO_3$  ( $CO_2$  is called carbonic anhydride.) Carbonic acid is known only in solution and has never been isolated in free state.

The carbonic acid is a dibasic acid and it forms two series of salts by replacement of one or both the hydrogen atoms.

$$H_2CO_3 \rightleftharpoons H^+ + HCO_3^- \rightleftharpoons 2H^+ + CO_3^{2-}$$

- (a) Acid salts, are also called bicarbonates or hydrogen carbonates. These contain  $HCO_3^-$  ions.
- (b) Normal salts, are also called carbonates. These contain  $CO_3^{2-}$  ions.

The metallic carbonates or bicarbonates are prepared by following methods:

(i) By passing CO<sub>2</sub> through the solution of base:

$$2\text{NaOH} + \text{CO}_2 \longrightarrow \text{Na}_2\text{CO}_3 + \text{H}_2\text{O}$$

$$\downarrow^{\text{CO}_2 + \text{H}_2\text{O}}$$

$$\text{NaHCO}_3$$

$$\text{Ca(OH)}_2 + \text{CO}_2 \longrightarrow \text{CaCO}_3 + \text{H}_2\text{O}$$

$$\downarrow^{\text{CO}_2 + \text{H}_2\text{O}}$$

$$\downarrow^{\text{CO}_2 + \text{H}_2\text{O}}$$

$$\text{Ca(HCO}_3)_2$$

(ii) By reacting basic oxides and CO2:

$$K_2O + CO_2 \longrightarrow K_2CO_3$$
  
 $Na_2O + CO_2 \longrightarrow Na_2CO_3$ 

(iii) By double decomposition, i.e., by using sodium carbonate :

$$CaCl_2 + Na_2CO_3 \longrightarrow CaCO_3 + 2NaCl$$
  
 $BaCl_2 + Na_2CO_3 \longrightarrow BaCO_3 + 2NaCl$ 

**Properties: (i) Solubility:** (a) Except alkali metals carbonates, all other carbonates are insoluble in water.

- (b) The bicarbonates are soluble in water. The bicarbonates of alkali metals are known in solid state while the bicarbonates of alkaline earth metals are only known in solutions.
- (ii) Action of heat: (a) All bicarbonates decompose on heating evolving carbon dioxide. The carbonate formed may further decompose except alkali metal carbonates.

$$Ca(HCO_3)_2 \longrightarrow CaCO_3 + H_2O + CO_2$$
  
 $2NaHCO_3 \longrightarrow Na_2CO_3 + H_2O + CO_2$ 

- (b) Alkali metal carbonates except Li<sub>2</sub>CO<sub>3</sub> do not decompose on heating.
- (c) All other carbonates decompose on heating with evolution of carbon dioxide.

$$ZnCO_3 \longrightarrow ZnO + CO_2$$
  
 $CaCO_3 \longrightarrow CaO + CO_2$   
 $CuCO_3 \longrightarrow CuO + CO_2$   
 $Ag_2CO_3 \longrightarrow 2Ag + CO_2 + \frac{1}{2}O_2$ 

(iii) Action of acids: Both carbonates and bicarbonates are decomposed by the action of acids with evolution of  $CO_2$  (effervescences).

$$Na_2CO_3 + 2HCI \longrightarrow 2NaCl + H_2O + CO_2$$
  
 $NaHCO_3 + HCl \longrightarrow NaCl + H_2O + CO_2$   
 $ZnCO_3 + H_2SO_4 \longrightarrow ZnSO_4 + H_2O + CO_2$ 

(iv) Action of MgSO<sub>4</sub>: This is the reagent with which carbonates and bicarbonates can be distinguished and tested. Soluble carbonates form an insoluble white precipitate with magnesium sulphate in cold.

$$Na_2CO_3 + MgSO_4 \longrightarrow MgCO_3 + Na_2SO_4$$
  
White ppt.

Bicarbonates do not form any white precipitate with magnesium sulphate in cold. However, when such solution is heated, a white precipitate appears.

(v) Effect of phenolphthalein: Soluble carbonates produce pink colour with phenolphthalein showing higher pH value while bicarbonates do not give pink colour with phenolphthalein.

### 3. Gaseous Fuels

Fuels are the substances which undergo combustion. As a result of their burning, they produce heat energy. During combustion, no undesirable product should be formed. The heat energy production depends on the presence of combustible substances such as carbon, carbon monoxide, carbonous matter, hydrogen, etc., in the fuels. Most common fuels are:

- (a) Solid fuels: Wood, lignite, peat, coke, charcoal, etc.
- **(b) Liquid fuels:** Petroleum products such as petrol, kerosene, spirits, etc.
- (c) Gaseous fuels: Water gas, producer gas, coal gas, oil gas, natural gas, etc.

Characteristics of good fuel: (i) It should have high calorific value.

- (ii) It should yield very little ash content.
- (iii) It should not give any offensive odour or any undesirable product during burning.
- (iv) It's cost of production should be low and it should be easily available.
  - (v) The combustion should be of moderate speed.

**Superiority of gaseous fuels:** Gaseous fuels are the best fuels. The following are the advantages of gaseous fuels over solid and liquid fuels:

- (i) Gaseous fuels leave no ash and there is lesser loss of heat during their combustion.
  - (ii) Gaseous fuels do not produce smoke.
  - (iii) They have high calorific value.
  - (iv) No special devices are required for their combustion.

(v) Gaseous fuels can flow through pipes and can be ignited at the moment's notice at any place where a burner is placed. Some of the important gaseous fuels are discussed below:

### (i) Producer Gas

Producer gas is mainly a mixture of carbon monoxide and nitrogen. It is prepared by the incomplete combustion of coal, coke or charcoal. The combustion is done in restricted supply of air.

$$\begin{array}{c} C + O_2 \longrightarrow CO_2 + 97.7 \text{ kcal} \\ CO_2 + C \longrightarrow 2CO - 38.3 \text{ kcal} \\ \hline 2C + O_2 \longrightarrow 2CO + 59.4 \text{ kcal} \end{array}$$

Initially, carbon dioxide is the main product but when it rises through the bed of coal, it combines with carbon, provided the temperature is 1000°C, forming carbon monoxide. Thus, heat is generated during its preparation. This heat can also be utilised if producer gas is generated on the spot and used while still hot.

Producer gas is poisonous, heavier than air and insoluble in water. It has a low calorific value. The CO burns and converted into  $\mathrm{CO}_2$  in air producing heat energy. The low calorific value (103 B.Th.U. per cubic ft) is due to the presence of large proportion of nitrogen in it. It is mainly used as a gaseous fuel in open hearth furnace in the manufacture of steel and glass. It is also used to heat coke ovens for the manufacture of coal gas.

## (ii) Water Gas

Water gas is mainly a mixture of CO and H<sub>2</sub>. It is made by blowing steam through the layers of incandescent (red hot) coal. The efficient working temperature is 1000–1400°C.

$$C + H_2O \longrightarrow CO + H_2 - 28 \text{ kcal}$$

Due to endothermic nature of this reaction, the coal cools down after sometime and the formation of carbon dioxide starts at low temperature. To check this formation, the current of steam is replaced by a blast of air. This raises the temperature of coal and steam is readmitted. In general, water gas consists of 40 volumes of CO, 50 volumes of  $H_2$ , 5 volumes of

The calorific value of water gas is fairly high (310 B.Th.U. per cubic ft). The calorific value of water gas is increased by carburetting, *i.e.*, adding gaseous hydrocarbons obtained by cracking of petroleum oils.

Water gas is used as a fuel and for the manufacture of hydrogen. It is also used for lighting purposes and in the manufacture of methyl alcohol. The flame of water gas is short and hot, it is thus used for welding purposes.

## (iii) Coal Gas

Coal gas is a mixture of hydrogen, methane, carbon monoxide, ethylene, acetylene, carbon dioxide, nitrogen and oxygen. It is a good gaseous fuel as it contains about 95% combustible gases. The calorific value of coal gas is 450–650 B.Th.U. per cubic ft. The average composition of coal gas by volume is:

Hydrogen	56%;	Ethylene, acetylene	2.5%
Methane	22.8%;	Carbon dioxide	1.3%
Carbon monoxide	10.9%;	Oxygen	0.5%
Nitrogen	5.0%		

Hydrogen, methane and carbon monoxide are non-illuminating but heat producing constituents. The unsaturated hydrocarbons produce illumination. Nitrogen, carbon dioxide and oxygen are present as impurities.

Coal gas is obtained by destructive distillation of coal at about 1000°C. For this purpose, coal is heated at 1000–1100°C in a large fire-clay retorts. The products of decomposition are: (i) coal gas (ii) coke (iii) coal tar (iv) ammonical liquor. One ton of bituminous coal gives about 13000 cubic ft of coal gas.

**Uses:** It is used:

- (i) as a fuel in the household and in metallurgical operations.
- (ii) in providing inert atmosphere in certain chemical processes.
  - (iii) in smelting of metals and alloys.
  - (iv) as a reducing agent.
  - (v) as an illuminating gas.

### (iv) Oil Gas

Oil gas is obtained by cracking of kerosene. It is a mixture of lower hydrocarbons, mainly CH<sub>4</sub>, C<sub>2</sub>H<sub>4</sub>, C<sub>2</sub>H<sub>2</sub>, etc.

A thin stream of oil is allowed to drop on the red hot surface of an iron retort. The kerosene is broken down into gaseous hydrocarbons.

$$C_{16}H_{34} \longrightarrow 6CH_4 + 2C_2H_4 + C_2H_2 + 4C$$

The gas mixture is passed through hydraulic main to remove tar and soluble impurities and then collected in gas holder.

Oil gas is generally used in laboratories.

Petrol gas is a mixture of petrol vapours and air. It is obtained by passing air through petrol (solvent oil). Nowadays, petrol gas is used in the laboratories instead of oil gas.

## (v) Natural Gas

Natural gas is found in regions rich in petroleum. The gas consists of chiefly methane. The approximate composition of a sample of natural gas is given below:

The composition may vary from place to place. Natural gas from certain regions has been found to have sufficient proportion of helium. Chief use of natural gas is as a fuel. It is also used for the production of hydrogen, carbon black and various petrochemicals.

## (vi) Liquefied Petroleum Gas (LPG)

Liquid or liquefied petroleum gas (LPG) is a clean burning gaseous fuel which contains  $C_3$  and  $C_4$  hydrocarbons of the alkane and alkene series. LPG contains hydrocarbons of such volatility that can exist as gases under normal temperature and atmospheric pressure, but can be easily liquefied under high pressure, *i.e.*, the critical temperature of the gaseous mixture (LMP) is nearly equal to room temperature. The main constituents of LPG are n-butane, isobutane, butene and propane.

LPG is generally isolated either from **natural gas** or from the **cracking units of petroleum refineries.** During fractional distillation of crude petroleum, the gases collected at the top of the fractionating tower which do not condense at all (hydrocarbons having low boiling points such as methane, ethane, propane, butanes, etc.) are used for making LPG. The mixture of lower hydrocarbons is condensed under high pressure in refrigeration units. However, traces of sulphur containing compounds such as ethyl mercaptan (C<sub>2</sub>H<sub>5</sub>SH) or methyl mercaptan (CH<sub>3</sub>SH) are deliberately added in order to detect any dangerous leakage from the gas cylinder.

The density of LPG is about 0.55g mL<sup>-1</sup> and is colourless, taşteless, odourless and non-toxic in nature. However, life is not possible in its gaseous atmosphere due to lack of oxygen, *i.e.*, it is suffocating in nature. In gaseous state it is twice heavy as air. It is highly inflammable and produces heat energy on combustion in air.

$$C_3H_8 + 5O_2 \longrightarrow 3CO_2 + 4H_2O + \text{Heat}$$
 
$$C_4H_{10} + \left(\frac{13}{2}\right)O_2 \longrightarrow 4CO_2 + 5H_2O + \text{Heat}$$

The average calorific value of LPG is 55 kJg<sup>-1</sup> or 29780 kcal/m<sup>3</sup>. LPG is used as a domestic fuel, direct motor fuel, laboratory gas and a source of petrochemicals. About 80% LPG is used nowadays in India as a domestic fuel (Cooking gas). Domestic installation consists of a LPG cylinder, pressure regulator, rubber tubing and a hot plate. On opening the cylinder valve with the help of pressure regulator, the pressure inside the cylinder is reduced causing LPG liquid to vaporise into gas. The gas through rubber tube reaches the burner of the hot plate where it is mixed with air and burnt.

## LPG is the safest fuel but requires certain simple precautions in day to day use.

- (i) As LPG is heavier than air and as such, it travels towards floor, so it is important that the flame should be at higher level than cylinder. Thus, it is recommended that hot plate level should be above cylinder height.
- (ii) There should be no electrical appliances like fridge in the kitchen which can cause electric spark during switch on or off.

- (iii) In case of smell of gas inside the kitchen, no flame should be produced and no electric switch be touched.
- (iv) The LPG cylinder should never be stored in cupboard.
- (v) Kitchen should be airy.
- (vi) After cooking is over, the pressure regulator should be turned off.

## LPG is an ideal fuel in modern living. The main advantages of LPG are :

- (a) It gives instant flame by just lighting a match box or lighter.
- (b) It gives instant heat, there is no need to wait for appliances to warm up.
- (c) It gives correct amount of heat required, as the size of the flame can be adjusted.
- (d) It gives comfort because cooking is quicker and the kitchen does not get heated or get dirty like other fuels.
- (e) It is much cheaper than other fuels.
- (f) It is easy to store. The cylinder occupies very little space. LPG connections can be transferred from one place to another.

## (vii) Gobar Gas or Bio-gas

The mixture of gases that can burn and produce heat energy, which is emitted from places where organic wastes (like animal dung, human excreta, vegetable waste, leaves, etc.) decay out of contact of air is called bio-gas or gobar gas.

Its main constituent is methane (60–70%). Other gases present are CO, H<sub>2</sub>, CO<sub>2</sub>, H<sub>2</sub>S, N<sub>2</sub>, etc. Bio-gas is combustible. It gives a blue flame with a lot of heat which may be used for cooking, lighting and as a fuel for petrol and diesel engines.

Organic waste is made to decay out of contact of air when bio-gas is produced. This process is called **anaerobic fermentation**. The waste that remains after fermentation called **slurry** is a very good fertilizer as the bacteria add a lot of nitrogen to the waste during fermentation, thus improving the quality of the fertilizer.

Bio-gas has become a very practical alternative energy resource in several rural areas of the country.

## 4. Carbides

Carbides are binary compounds of carbon with elements of lower or about equal electronegativity. Carbides are classified into three types on the basis of chemical bonding. These are salt-like carbides, covalent carbides and interstitial or alloy like carbides. Carbides are generally prepared by heating the element or its oxide with carbon or hydrocarbon at very high temperatures.

$$\begin{array}{c} Ba + 2C \longrightarrow BaC_2 \\ 2Li + 2C \longrightarrow Li_2C_2 \\ CaO + 3C \longrightarrow CaC_2 + CO \\ 4Li + C_2H_2 \longrightarrow Li_2C_2 + 2LiH \end{array}$$

**Salt-like carbides:** These carbides are formed by the metals of groups IA, IIA and IIIA (except boron), coinage metals, zinc, cadmium and some lanthanides. Depending on

the nature of the hydrocarbon formed during hydrolysis by water or dilute HCl, the ionic carbides can be further classified into the following types:

- (i) Acetylides: These are the ionic carbides which yield acetylene on hydrolysis. These are regarded as derivatives of acetylene and are thus called acetylides. The alkali metals and copper, silver and gold form  $M_2C_2$  type compounds. The alkaline earth metals, zinc and cadmium give  $MC_2$  type carbides. These carbides are believed to contain  $[C = C]^{2-}$  groups. Two types of crystal structures characterise these carbides. Both are tetragonal and are derived from sodium chloride structure by replacement of  $Cl^-$  ions by  $C_2^{2-}$  ions.
- (ii) Methanides: These carbides evolve methane on hydrolysis. These are regarded as derivatives of methane and are called methanides. Al<sub>4</sub>C<sub>3</sub>, Be<sub>2</sub>C, Mn<sub>3</sub>C,etc., are some examples of methanides. These contain C<sup>4-</sup> groups.
- (iii) Allylides: These carbides evolve allylene (methyl acetylene) on hydrolysis. The only example of this type is  $Mg_2C_3$ . It contains  $C_3^{4-}$  discrete groups.

$$Mg_2C_3 + 4H_2O \longrightarrow 2Mg(OH)_2 + CH_3 \longrightarrow C \equiv CH$$
Propyne

(iv) Mixed carbides: These carbides yield a mixture of hydrocarbons on hydrolysis. Carbides of iron group,  $UC_2$  and  $ThC_2$  belong to this class.

**Covalent carbides:** The only true covalent carbides are those of silicon (SiC carborundum) and boron (B<sub>4</sub>C and B<sub>13</sub>C<sub>2</sub>). These are chemically inert and extremely hard materials. On account of hardness, these carbides are used as abrasives.

Silicon carbide is produced by heating quartz or sand with an excess of coke in an electric arc furnace.

$$SiO_2 + 3C \xrightarrow{2000-2500^{\circ}C} SiC + 2CO\uparrow$$

**Metallic or interstitial carbides:** In these carbides, small carbon atoms occupy interstitial positions in the crystal lattices of the metals. These are of two types: MC (M = Ti, Zr, Hf, V, Nb, Ta, Mo, W) and  $M_2C$  (M = V, Mo and W). These carbides possess metallic lustre, high electrical conductivity and are chemically inert. These are extremely hard like diamond and possess very high melting points.

- **Uses:** (i) Calcium carbide is used to prepare acetylene. Acetylene is the starting material for many organic compounds. It is also used for production of oxy-acetylene flame employed for welding purposes.
- (ii) SiC, being hard substance, is used as abrasive. Boron carbide is also used as abrasive and shield from radiations. It is used for the construction of atomic reactors.
- (iii) Carbides which can withstand high temperature are used widely in furnace lining.
- (iv) Tungsten carbide, WC, is used for the manufacture of high speed tools.

## 9.6 SILICON

Silicon is the second most abundant element occurring in the earth's crust (about 28% by weight). Silicon and oxygen make up 75% of the crust of the earth. Unlike carbon, it is never found in free state but always in combined state. It is an important constituent of igneous rocks which consists of silicates of magnesium, aluminium, potassium or iron. Silicon is widely present as silica (SiO<sub>2</sub>) in various forms such as sand, quartz, flint, etc. Silicon dioxide, SiO<sub>2</sub> has a melting point of 1710°C.

Silicon is obtained by the reduction of silica. It exists in two allotropic forms: (a) amorphous and (b) crystalline. The amorphous variety is obtained by heating dry powdered silica with magnesium.

$$SiO_2 + 2Mg \longrightarrow Si + 2MgO$$

The crystalline variety is obtained by heating a finely powdered sand or quartz with carbon in an electric furnace. A small amount of iron is added to prevent the formation of carborundum (SiC).

$$SiO_2 + 2C \longrightarrow Si + 2CO$$

High purity silicon can be prepared by reducing SiCl<sub>4</sub> with magnesium.

$$SiCl_4 + 2Mg \longrightarrow Si + 2MgCl_2$$

The magnesium chloride, being water soluble, is then washed away from the silicon. The final purification of silicon takes place by **zone-refining.** 

Amorphous silicon is chemically more reactive than crystalline silicon. Amorphous silicon is a brownish powder. It burns brilliantly in oxygen and ignites spontaneously in fluorine.

$$Si + O_2 \longrightarrow SiO_2$$
  
 $Si + 2F_2 \longrightarrow SiF_4$ 

It decomposes steam at red heat. It dissolves in the mixture of HNO<sub>3</sub> and HCl. However, it dissolves readily in alkalies.

$$Si + 2H2O \longrightarrow SiO2 + 2H2$$

$$Si + 2KOH + H2O \longrightarrow K2SiO3 + 2H2$$

$$Na2CO3 + Si \longrightarrow Na2SiO3 + C$$

It combines with certain metals forming silicides.

$$2Mg + Si \longrightarrow Mg_2Si$$

When amorphous silicon is strongly heated, it fuses and on cooling solidifies to the crystalline form. It is very hard crystalline silicon, does not burn in oxygen but it readily combines with fluorine. It dissolves in mixture of HNO<sub>3</sub> and HF. When fused with alkali, it gives a silicate.

$$Na_2CO_3 + Si \longrightarrow Na_2SiO_3 + C$$

Silicon is used in the manufacture of certain alloys such as ferrosilicon, silicon bronze, manganese silicon bronze, etc. These alloys possess high strength and hardness and resistant to the attack of acids.

One outstanding property of silicon in a high state of purity is its electrical conductivity. It acts as a **semiconductor**, *i.e.*, it does not conduct electricity until a cartain electric voltage is applied, but beyond that it conducts moderately. Its conductivity

properties can be changed by a process known as **doping**, *i.e.*, placing other atoms in a crystal of pure silicon.

The excesses (*n*-type) and deficiencies (*p*-type) of electrons result from inserting arsenic and boron atoms respectively in the place of silicon atoms in the crystalline structure. In 1947, an electrical device called the **transistor** was invented. The simplest device used layers of *n*-*p*-*n* or *p*-*n*-*p*-doped silicon. The most revolutionary application of silicon's semiconductor properties has been in the design of **integrated circuits**, computer memories and even whole computers called **microprocessors** on tiny chips of silicon. These are used in calculators, cameras, watches, toys, cardiac pacemakers and many other products.

## 9.7 COMPOUNDS OF SILICON

## 1. Carborundum (Silicon Carbide), SiC

It is obtained when a mixture of sand, carbon, common salt and saw dust is strongly heated in an electric furnace.

$$SiO_2 + 3C \longrightarrow SiC + 2CO$$

Salt is added to act as flux and saw dust makes the mass porous. Two carbon rods connected by a thin carbon core act as electrodes in the furnace. Carborundum is formed round the central core of carbon. It is crushed, washed with H<sub>2</sub>SO<sub>4</sub>, NaOH, H<sub>2</sub>O and then dried.

**Properties:** (i) Pure carborundum is colourless but commercial samples possess yellow, green or blue colour.

- (ii) It is very hard mass. However, its hardness is less than diamond.
- (iii) It is chemically inert and resists the attack of almost all the reagents except fused caustic soda. The fused alkali dissolves it in presence of air.

$$4\text{NaOH} + \text{SiC} + 2\text{O}_2 \longrightarrow \text{Na}_2\text{SiO}_3 + \text{Na}_2\text{CO}_3 + 2\text{H}_2\text{O}$$
 Its structure is similar to diamond.

**Uses:** It is used as an abrasive instead of emery. It is used to make grind-stones, knife sharpeners, etc.

## 2. Sodium Silicate, Na<sub>2</sub>SiO<sub>3</sub> (Water Glass)

It is commercially called water glass. Chemically it is sodium metasilicate containing an excess of silica. Its composition may vary from Na<sub>2</sub>SiO<sub>3</sub>·SiO<sub>2</sub> to Na<sub>2</sub>SiO<sub>3</sub>·3SiO<sub>2</sub>.

It is obtained by fusing soda ash (Na<sub>2</sub>CO<sub>3</sub>) with pure sand at a high temperature.

$$Na_2CO_3 + SiO_2 \longrightarrow Na_2SiO_3 + CO_2 \uparrow$$

The resulting mass is extracted with water and the solution is evaporated to get a syrupy mass known as water glass.

**Properties:** It is soluble in water. The solution is alkaline due to hydrolysis.

$$Na_2SiO_3 + 2H_2O \implies 2NaOH + H_2SiO_3$$

If in a solution of sodium silicate of density 1.1, some coloured salts like cobalt nitrate, nickel chloride, ferrous

sulphate, copper sulphate, etc., are placed and whole solution is left as such for a night, beautiful hollow tubes of metallic silicate gels possessing different colours shoot up from these crystals and look like plants. This is called **silica garden** or **chemical garden**.

Uses: It is used:

- (a) in fire proofing of wood and textiles.
- (b) as a preservative for eggs.
- (c) as an adhesive cement for joining pieces of china clay.
- (d) in the soap industry as a filler for a cheaper variety of soap.
- (e) in paint industry and calico printing.
- (f) for making silica gel, SiO<sub>2</sub>·xH<sub>2</sub>O. When a solution of Na<sub>2</sub>SiO<sub>3</sub> is acidified with HCl, a gelatinous precipitate of silicic (H<sub>2</sub>SiO<sub>3</sub>) acid is slowly formed.

$$Na_2SiO_3 + 2HCl \longrightarrow 2NaCl + H_2SiO_3$$

If most of the water is carefully removed, the jelly like precipitate of H<sub>2</sub>SiO<sub>3</sub> is converted into a solid product which is called silica gel. It possesses excellent absorption property of gases and vapours.

#### 3. Silicones

These are organosilicon polymers containing Si—O—Si linkages. These are formed by the hydrolysis of alkyl or aryl substituted chlorosilanes and their subsequent polymerisation. The alkyl or aryl substituted chlorosilanes are prepared by the reaction of Grignard reagent and silicon tetrachloride.

$$RMgCl + SiCl_4 \longrightarrow R - SiCl_3 + MgCl_2$$
Grignard reagent

$$2RMgCl + SiCl_4 \longrightarrow R_2SiCl_2 + 2MgCl_2$$

$$3RMgCl + SiCl_4 \longrightarrow R_3SiCl + 3MgCl_2$$

R stands for 
$$-CH_3$$
,  $-C_2H_5$  or  $-C_6H_5$  groups.

Hydrolysis of substituted chlorosilanes yield corresponding silanols which undergo polymerisation.

Polymerisation of dialkyl silandiol yields linear thermoplastic polymer.

Polymerisation continues on both the ends and thus chain increases in length.

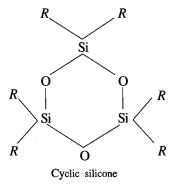

RSiCl<sub>3</sub> on hydrolysis gives a cross linked silicone. The formation can be explained in three steps:

Cyclic (ring) silicones are formed when water is eliminated from the terminal —OH groups of linear silicones.

R

Cross linked silicone

R

 $R_3$ SiCl on hydrolysis forms only a dimer

$$R_3$$
Si O  $\stackrel{\cdot}{H} + \stackrel{\cdot}{O}\stackrel{\cdot}{H}$  Si $R_3 \longrightarrow R_3$ Si—O—Si $R_3$ 

**Properties:** (i) The lower silicones are oily liquids but higher members containing long chains or ring structures are waxy and rubber like solids.

- (ii) Silicones are stable towards heat.
- (iii) Chemical reagents have no action on silicones.
- (iv) These are non-toxic.
- (v) Viscosity of silicone oils remains the same at different temperatures.
  - (vi) Silicones are good electrical insulators.
  - (vii) These are water repellants.

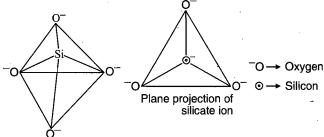

**Uses:** (i) Silicone oils are used for high temperature oil baths, high vacuum pumps and low temperature lubrication.

- (ii) These are used in making water-proof cloth and paper by exposing cloth or paper to the silicone vapour.
- (iii) These are used as insulating materials for electric motors and other electrical appliances.
- (iv) These are mixed with paints and enamels to make them resistant to the effects of high temperature, sunlight, chemicals and damp.
- (v) These are used in making vaseline like greases which are used as lubricants in aeroplanes.
- (vi) Silicone-rubbers are useful as they retain their elasticity over a range of temperatures.

#### 4. Silicates

Silicates are metal derivatives of silicic acid, H<sub>4</sub>SiO<sub>4</sub> or Si(OH)<sub>4</sub>. Silicates are formed by heating metal oxide or metal carbonates with sand, *e.g.*,

$$Na_2CO_3 - \xrightarrow{Fused with sand} Na_4SiO_4$$
,  $Na_2(SiO_3)_n$ , etc.

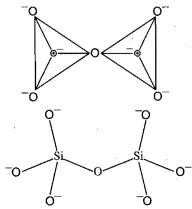

Silicates have basic unit of  $SiO_4^{4-}$ , each silicon atom is bonded with four oxide ions tetrahedrally.

There are following types of silicates:

- (i) Orthosilicates: These silicates contain single discrete unit of  $SiO_4^{4-}$  tetrahedra,
- e.g., Zircon ZrSiO<sub>4</sub>; Forsterite or Olivine Mg<sub>2</sub>SiO<sub>4</sub> Phenacite Be<sub>2</sub>SiO<sub>4</sub>; Willemite Zn<sub>2</sub>SiO<sub>4</sub>
- (ii) Pyrosilicates: These silicates contain two units of SiO<sub>4</sub><sup>4</sup> joined along a corner containing oxygen atom. These are also called as island silicates.

Pyrosilicate ion Si<sub>2</sub>O<sub>7</sub><sup>6-</sup>,

e.g., Thortveitite

 $Sc_2(Si_2O_7);$ 

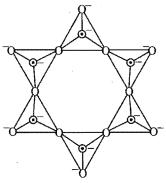

Hemimorphite

 $Zn_3(Si_2O_7)Zn(OH)_2 \cdot H_2O$ 

(iii) Cyclic structure: Cyclic or ring silicates have general formula  $(SiO_3^{2-})_n$  or  $(SiO_3)_n^{2n-}$ .

Structure and example of cyclic silicates containing  $Si_3O_9^{6-}$  and  $Si_6O_{18}^{12-}$  ions are given below:

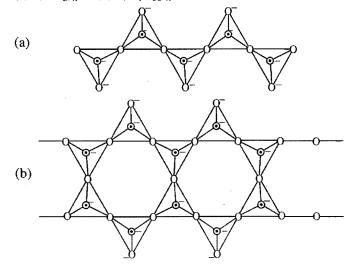

e.g., Beryl Be<sub>3</sub>Al<sub>2</sub>Si<sub>6</sub>O<sub>18</sub>; Benitoite BaTiSi<sub>3</sub>O<sub>9</sub>
Wollastonite Ca<sub>3</sub>Si<sub>3</sub>O<sub>9</sub>; Catapleite Na<sub>2</sub>ZrSi<sub>3</sub>O<sub>9</sub>·2H<sub>2</sub>O

(iv) Chain silicates: Chain silicates are formed by sharing two oxygen atoms by each tetrahedra. Anions of chain silicate have two general formulae,

(a)  $(SiO_3)_n^{2n-}$  (b)  $(Si_4O_{11})_n^{6n-}$ 

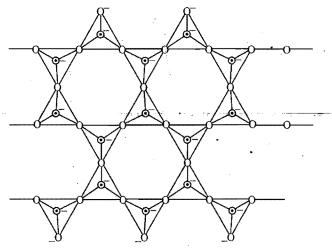

e.g., Synthetic silicates Li<sub>2</sub>SiO<sub>3</sub>, Na<sub>2</sub>SiO<sub>3</sub>;

 $\begin{array}{lll} \text{Spodumene} & \text{LiAl}(\text{SiO}_3)_2; \\ \text{Jadeite} & \text{NaAl}(\text{SiO}_3)_2; \\ \text{Enstatite} & \text{MgSiO}_3; \\ \text{Diopside} & \text{CaMg}(\text{SiO}_3)_2; \\ \end{array}$ 

Tremolite  $Ca_2Mg_5(Si_4O_{11})_2(OH)_2$ 

(v) Two dimensional sheet silicates: In such silicates, three oxygen atoms of each tetrahedra are shared with adjacent  $SiO_4^{4-}$  tetrahedra, such sharing forms two dimensional sheet structure with general formula  $(Si_2O_5)_n^{2n-}$ .

e.g., Talc  $Mg(Si_2O_5)_2Mg(OH)_2$ Kaolin  $Al_2(OH)_4(Si_2O_5)$ 

(vi) Three dimensional sheet silicates: These silicates involve all four oxygen atoms in sharing with adjacent SiO<sub>4</sub><sup>4</sup> tetrahedra.

e.g., Quartz, Tridymite, Crystobalite, Feldspars, Zeolites and Ultramarines.

Zeolites are a class of three dimensional aluminosilicates. They carry a negative charge on aluminosilicate framework which is compensated by neighbouring alkali-metal or alkaline-earth cations. They possess open structures consisting of polyhedra cavities of uniform size and shape. Most zeolites (natural or synthetic) accommodate water molecules in their cavities, where they provide a mobile phase for the migration of the charge-compensating cations. This enables zeolites to serve as ion - exchange materials and is the key to their ability to soften water.

When hard water is passed through a column packed with a zeolite, the calcium and magnesium ions exchange with the sodium ions,

$$2\text{NaZ}(s) + \text{Ca}^{2+}(aq.) \Longrightarrow \text{CaZ}_2(s) + 2\text{Na}^+(aq.)$$

When the ion exchange capacity of the zeolite is exhausted, this reaction can be reversed by passing a concentrated solution of sodium chloride through the zeolite to regenerate it in the sodium form.

#### 👼 5. Glass

Glass is a transparent or translucent amorphous supercooled solid solution of silicates and borates. The most common silicates present are those of potassium, calcium and lead. Its composition is variable as it is not a true compound.

An approximate formula for ordinary glass may be given as,  $R_2O \cdot MO \cdot 6SiO_2$ 

where R = Na or K and M = Ca, Ba, Zn or Pb.

SiO<sub>2</sub> may be replaced by Al<sub>2</sub>O<sub>3</sub>, B<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>. When glass is heated, it does not melt at a fixed temperature. However, it gradually softens and can be moulded into any desired shape. It is the property of glass which makes it a useful material for making articles of different shapes. Glass melts into a liquid at a very high temperature.

**Raw materials:** Following are the main raw materials used in the manufacture of glass:

- (a) Acidic oxides: A number of acidic oxides are used. The choice depends upon the quality of glass to be manufactured.
- (i) Silica: Sand of uniform size is used, *i.e.*, neither too fine nor too coarse. Fine variety makes the reaction violent while coarse variety slows down the reaction. It should be free from iron oxide and organic matter.
- (ii) Boron trioxide, B<sub>2</sub>O<sub>3</sub>: This is introduced in the form of boric acid or borax. It is used when a glass of low coefficient of expansion is required.
- (iii) Phosphorus pentoxide, P<sub>2</sub>O<sub>5</sub>: It is introduced in the form of calcium phosphate. It is used when opalescent glass is required.
- **(b) Basic oxides:** One or more of the following basic oxides are used:

Lithium, sodium, potassium, calcium, barium, magnesium, lead and zinc oxides. Sodium is introduced in the form of sodium carbonate (Na<sub>2</sub>CO<sub>3</sub>), sodium nitrate (NaNO<sub>3</sub>) or sodium sulphate (Na<sub>2</sub>SO<sub>4</sub>) and carbon mixture. Potassium is added as potassium carbonate (K<sub>2</sub>CO<sub>3</sub>) or potassium nitrate (KNO<sub>3</sub>). Calcium is added as CaCO<sub>3</sub> or CaO. Barium is put in as BaCO<sub>3</sub>. Magnesium is added as MgCO<sub>3</sub>. Lead oxides are put in as such. Zinc oxide is used when heat resistant glass is to be obtained.

(c) Colouring materials: Coloured glasses are obtained by adding certain metallic oxides or salts in the fused mass. The following is the list of various substances used for imparting a particular colour to the glass.

Substance	Colour imparte
Ferric oxide	Yellow
Chromic oxide	Green
Cobalt oxide	Blue
Selenium metal	Red
Manganese oxide	Purple
Cuprous oxide	Red
Cadmium sulphide	Yellow
Nickel oxide,	
Cobalt oxide,	Black
Manganese oxide	

**Manufacture:** The raw materials used in the manufacture of glass depend on the variety of glass. For ordinary glass, the raw materials are sand, washing soda and limestone. These are ground separately and mixed in the proper proportion, *i.e.*, in the ratio of 100:35:15. The mixture is known as "batch". Broken glass pieces known as "cullet" are added to the mixture of raw materials. Cullet melts at low temperature and helps in melting the rest of charge at low temperature.

The charge is fused now either in a pot or tank furnace at about 1400°C. This temperature is obtained by burning producer gas. Both the furnaces work on the regenerative system of heat economy. A tank furnace is used where the output expected is large but where the highest quality of glass is desired, the pot furnace is used. In tank furnace, the process is continuous while in pot furnace the process is discontinuous.

**Pot furnace:** A pot is a large monkey shaped crucible of the type given in Fig. 9.6. In a pot furnace a number of such pots are arranged in a circle. These are heated by burning producer gas.

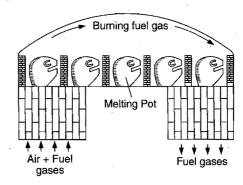

Fig. 9.6 Pot furnace

**Tank furnace:** It is a large rectangular clay tank in which raw materials are fused. It is also heated by producer gas (Fig. 9.7).

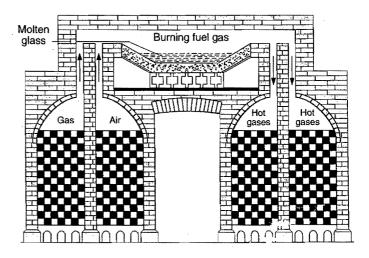

Fig. 9.7 Tank furnace

The free silica decomposes the carbonates, setting the evolution of CO<sub>2</sub>.

$$Na_2CO_3 + SiO_2 \longrightarrow Na_2SiO_3 + CO_2$$
  
 $CaCO_3 + SiO_2 \longrightarrow CaSiO_3 + CO_2$ 

At 1400°C silica also dissolves in the silicates of sodium and calcium.

$$Na_2SiO_3 + CaSiO_3 + 4SiO_2 \longrightarrow \underbrace{Na_2SiO_3 \cdot CaSiO_3 \cdot 4SiO_2}_{Glass}$$

The heating is continued till bubbles of CO<sub>2</sub> no longer rise and the mass melts to a clear liquid. The clear viscous liquid is then poured into moulds or stamped with dies to produce desired articles.

**Annealing:** The glass if cooled rapidly becomes brittle and fragile. The articles of glass are cooled neither very slowly nor very rapidly. These are made to pass through a long tunnel like furnace which is very hot at the mouth end and very cold at the tail end, *i.e.*, the articles are cooled gradually during passage through the tunnel. This process is termed as annealing and takes several days for completion.

The articles so cooled require some finishing such as cutting, grinding, polishing, etc. Only the finished products are sold in the market.

## Varieties of glass:

By varying the composition of batch, several varieties of glass are obtained. Some of the varieties are the following:

- (i) Soda glass or soft glass: It is a mixture of sodium and calcium silicates. It is a cheap variety. It softens at a comparatively low temperature and can be easily shaped into different forms. It is used in making glass tubes, window panes, bottles, dishes, etc.
- (ii) Potash glass or hard glass: It is a mixture of potassium and calcium silicates. It fuses with difficulty. It is more resistant to the action of water and acids. It is used for making hard glass apparatus.
- (iii) Flint glass: It is a mixture of potassium and lead silicates. It has a very high refractive index and is used for making electric bulbs and optical instruments.
- (iv) Jena glass: It is a mixture of zinc and barium borosilicates. It is resistant to heat, shock and common reagents. It is used for making good quality of glasswares.
- (v) Pyrex glass: It is a mixture of zinc, barium borosilicates and alumino silicates. It is similar to jena glass in properties. It can withstand sudden changes in temperature and is highly suitable for laboratory glassware and oven glassware. Its approximate composition is: silica 80%, Na<sub>2</sub>O 4%, CaO 0.5%, K<sub>2</sub>O 0.5%, B<sub>2</sub>O<sub>3</sub> 12%, Al<sub>2</sub>O<sub>3</sub> 3%.
- (vi) Crooke's glass: It is a special type of glass containing cerium oxide. It does not allow the passage of ultraviolet rays. It is used for making lenses.

### Etching of glass:

Glass is attacked by hydrofluoric acid. This property is used in the etching of glass.

The glass to be etched is coated with a thin layer of wax and the design to be produced is scratched with a needle or stylus. An aqueous solution of hydrofluoric acid is applied to the exposed part. After sometime it is placed in water and wax is removed from the surface. The marks are engraved on the exposed parts.

## 9.**8** TIN

**Occurrence:** Tin does not occur free in nature. The most important ore is cassiterite, SnO<sub>2</sub>, which is also known as tin stone. The ore is usually associated with siliceous matter, tungstates of iron (FeWO<sub>4</sub>) and manganese (MnWO<sub>4</sub>). It also exists along with the pyrites of copper, iron and zinc.

**Extraction:** Tin is extracted from cassiterite ore. The extraction involves the following steps:

- (a) Concentration: The ore is crushed and powdered. It is washed with running water which removes lighter siliceous matter. Iron tungstate is removed by electromagnetic separator. The ore is now roasted in a current of air to remove sulphur and arsenic as  $SO_2$  and  $As_2O_3$ , respectively.
- **(b) Smelting:** The roasted ore is mixed with about one fifth its mass of powdered anthracite (carbon) and a little limestone (flux). The mixture is subjected to heat in a reverberatory furnace when tin oxide is reduced to tin metal. The liquid metal is drawn off from the furnace.

$$SnO_2 + 2C \longrightarrow Sn + 2CO$$

The crude tin metal contains a number of impurities. It is further purified by liquation and poling. The crude metal is heated gently on the sloping hearth of reverberatory furnace. The tin metal flows down leaving behind iron, copper, tungsten, etc. The molten metal is now stirred with a green wood pole whereby impurities like S, As are oxidised, and any tin oxide formed is reduced by the hydrocarbons of wood.

**Properties:** (i) Tin is a silvery white metal. It melts at 232°C and boils at 2270°C. It is not affected by air.

- (ii) It is malleable and ductile but at 200°C, it becomes brittle and can be powdered.
- (iii) It produces a peculiar sound whenever it is bent. The cracking sound is known as *tincry*.
- (iv) It exists in three allotropic forms. White tin is the common and most stable.

Density Grey 
$$\frac{18^{\circ}\text{C}}{5.74}$$
 White  $\frac{170^{\circ}\text{C}}{7.32}$  Rhombic 6.55

The conversion of white tin to grey tin in cold countries is accompanied by decrease in density, *i.e.*, increase in volume. It is very brittle and easily comes into powdered form. This is termed as *tin disease* or *tin pest* or *tin plague*.

(v) Tin is much less reactive than the metals of group IA, IIA and IIIA. When heated in presence of oxygen at 1500-1600°C, it burns with bright flame forming stannic oxide, SnO<sub>2</sub>.

$$Sn + O_2 \xrightarrow{Heat} SnO_2$$

It is not attacked by water. Molten tin decomposes steam with liberation of hydrogen.

(vi) Tin is not attacked by organic acids. This property is utilised for tinning cooking utensils made of copper or brass. It dissolves slowly in dil. HCl but readily in conc. HCl.

$$Sn + 2HCl \longrightarrow SnCl_2 + H_2$$

It dissolves in dil. H<sub>2</sub>SO<sub>4</sub> as well as in conc. H<sub>2</sub>SO<sub>4</sub>.

$$Sn + H_2SO_4(dil.) \longrightarrow SnSO_4 + H_2$$

$$Sn + 4H_2SO_4(conc.) \longrightarrow Sn(SO_4)_2 + 2SO_2 + 4H_2O$$

Dilute HNO<sub>3</sub> dissolves tin with the formation of ammonium nitrate.

$$4[Sn + 2HNO_3 \longrightarrow Sn(NO_3)_2 + 2H]$$

$$HNO_3 + 8H \longrightarrow NH_3 + 3H_2O$$

$$NH_3 + HNO_3 \longrightarrow NH_4NO_3$$

$$4Sn + 10HNO_3 \longrightarrow 4Sn(NO_3)_2 + NH_4NO_3 + 3H_2O$$

Conc. HNO<sub>3</sub> oxidises Sn into metastannic acid.

$$2[2HNO_3 \longrightarrow H_2O + 2NO_2 + O]$$

$$Sn + 2O + H_2O \longrightarrow H_2SnO_3$$

$$Sn + 4HNO_3 \longrightarrow H_2SnO_3 + 4NO_2 + H_2O$$

(vii) Tin dissolves in hot alkali solutions forming stannates.

$$Sn + 2NaOH + H_2O \longrightarrow Na_2SnO_3 + 2H_2$$

(viii) Tin directly combines with halogens and sulphur.

$$Sn + 2Cl_2 \longrightarrow SnCl_4$$
 (Stannic chloride)  
 $Sn + 2S \longrightarrow SnS_2$  (Stannic sulphide)

**Uses:** (i) The metal is extensively used in tinning brass utensils. Organic acids present in the food stuff attack the utensils which are made of copper, brass, etc. This may cause food poisoning. The utensils are protected by tinning, *i.e.*, depositing a thin layer of tin on the surface of utensils. The vessel to be tinned is perfectly cleaned and heated. A pinch of NH<sub>4</sub>Cl is sprinkled to remove the oxide film. A little tin is now fused on the clean surface and then rubbed over with the help of cotton rag to have a uniform layer.

- (ii) It is largely used in forming a protective coating over iron. The process of depositing tin over the sheets of iron or steel is called tin plating. Tin plating is done either mechanically or electrically.
- (iii) Tin in the form of tin foil is used for wrapping cigarettes, confectionary and for making the tooth-paste tubes.
  - (iv) Tin amalgam is used in making mirrors.
  - (v) It is used for making useful alloys.

Name	Composition	Uses
(i) Solder	Sn 67%, Pb 33%	in soldering
(ii) Rose metal	Sn 28%, Pb 22%, Bi 50%	for electric fuses
(iii) Bronze	Cu 75-90%, Sn 25-10%	for utensils, statues
	•	and coils
(iv) Bell metal	Cu 80%, Sn 20%	bells and gongs
(v) Type metal	Sn 3%, Pb 82%, Sb 15%	printing types
(vi) Britannia metal	Sn 86%, Sb 12%, Cu 2%	cheap table ware

## 9.9 COMPOUNDS OF TIN

#### 1. Stannous Oxide, SnO

**Preparation:** (a) It is prepared from stannous chloride by following methods.

(i) Sodium hydroxide is added to stannous chloride. The stannous hydroxide thus formed is heated in an atmosphere of CO<sub>2</sub> when stannous oxide is formed.

$$SnCl_2 + 2NaOH \longrightarrow Sn(OH)_2 + 2NaCl$$
  
 $Sn(OH)_2 \xrightarrow{CO_2} SnO + H_2O$ 

(ii) A mixture of solid stannous chloride and sodium carbonate is heated in atmosphere of CO<sub>2</sub>, when stannous oxide is formed.

$$SnCl_2 + Na_2CO_3 \longrightarrow SnO + CO_2 + 2NaCl$$

(b) It may also be prepared by heating stannous oxalate in absence of air.

$$Sn(COO)_2 \longrightarrow SnO + CO + CO_2$$

**Properties:** (i) It is a dark grey or black powder. It is insoluble in water.

(ii) It burns in air with incandescence forming stannic oxide, SnO<sub>2</sub>.

$$2SnO + O_2 \longrightarrow 2SnO_2$$

(iii) It is an amphoteric oxide. It dissolves both in acids and alkalies.

$$\begin{array}{c} SnO + 2HCl \longrightarrow SnCl_2 + H_2O \\ & Stannous \\ & chloride \\ SnO + 2NaOH \longrightarrow Na_2SnO_2 + H_2O \\ & Sod. \ stannite \end{array}$$

Stannites are known only in aqueous solutions. Stannites absorb oxygen from air and oxidised to stannates which are stable in nature.

$$2Na_2SnO_2 + O_2 \longrightarrow 2Na_2SnO_3$$
  
Sod. stannate

## 2. Stannic Oxide, SnO<sub>2</sub>

It is found in nature as cassiterite or tin stone.

**Preparation:** It may be prepared by heating tin in air or by heating metastannic acid which is obtained by reacting tin with concentrated nitric acid.

$$Sn + O_2 \longrightarrow SnO_2$$
  
 $Sn + 4HNO_3 \longrightarrow H_2SnO_3 + 4NO_2 + H_2O_3$ 

$$H_2SnO_3 \longrightarrow SnO_2 + H_2O$$
  
Metastannic acid

**Properties:** It is a white powder, insoluble in water. It is somewhat unreactive. However, it dissolves in conc. H<sub>2</sub>SO<sub>4</sub> forming stannic sulphate.

$$SnO_2 + 2H_2SO_4 \longrightarrow Sn(SO_4)_2 + 2H_2O$$

When the solution is diluted, stannic oxide is reprecipitated.

$$Sn(SO_4)_2 + 2H_2O \longrightarrow SnO_2 + 2H_2SO_4$$

It readily dissolves in alkalies forming stannates.

$$SnO_2 + 2KOH \longrightarrow K_2SnO_3 + H_2O$$

Stannates are used as mordants in dyeing. It is used in the manufacture of pottery and glass in the form of white glazes.

## 3. Stannous Chloride, SnCl<sub>2</sub>

**Preparation:** (i) Hydrated stannous chloride SnCl<sub>2</sub>·2H<sub>2</sub>O is prepared by dissolving tin in hot concentrated hydrochloric acid and subjecting the solution to crystallisation.

$$Sn + 2HCl \longrightarrow SnCl_2 + H_2$$

Hydrated stannous chloride consists of two molecules of water as water of crystallisation, i.e., SnCl<sub>2</sub>·2H<sub>2</sub>O.

Anhydrous salt cannot be obtained by heating the hydrated salt as it undergoes hydrolysis and a white solid of tin hydroxy chloride is formed.

$$SnCl_2 \cdot 2H_2O \longrightarrow Sn(OH)Cl + HCl + H_2O$$

(ii) Anhydrous stannous chloride is formed when dry HCl gas is passed over hot tin.

$$Sn + 2HCl (gas) \longrightarrow SnCl_2 + H_2$$

It can also be obtained when a mixture of Sn and calculated quantity of mercuric chloride is heated.

$$Sn + HgCl_2 \longrightarrow SnCl_2 + Hg$$

**Properties:** (i) It is a white crystalline solid. It is soluble in water, alcohol and ether.

- (ii) In water, it is soon hydrolysed. However in presence of HCl (acid), hydrolysis is reversed.
- (iii) It forms a white precipitate with alkalies. The precipitate of stannous hydroxide, however, dissolves in excess of alkali.

$$SnCl_2 + 2NaOH \longrightarrow Sn(OH)_2 + 2NaCl$$
  
 $Sn(OH)_2 + 2NaOH \longrightarrow Na_2SnO_2 + 2H_2O$   
Sodium stannite

(iv) It forms a dark brown precipitate of stannous sulphide on passing H<sub>2</sub>S through its solution. The precipitate dissolves in yellow ammonium sulphide.

$$\begin{array}{c} SnCl_2 + H_2S \longrightarrow SnS + 2HCl \\ SnS + (NH_4)_2S_2 \longrightarrow (NH_4)_2SnS_3 \\ \text{Yellow ammonium sulphide} & \text{Ammonium thiostannate} \end{array}$$

- (v) It is a strong reducing agent. Few examples are given below:
- (a) It reduces mercuric chloride to mercurous chloride (white ppt.) and finally to metallic mercury (dark grey or black).

$$2HgCl_2 \ + \ SnCl_2 \longrightarrow Hg_2Cl_2 \ + \ SnCl_4$$
 Mercurous chiloride

$$Hg_2Cl_2 + SnCl_2 \longrightarrow 2Hg + SnCl_4$$

(b) It reduces ferric salts to ferrous salts and cupric salts into cuprous salts.

$$2\text{FeCl}_3 + \text{SnCl}_2 \longrightarrow 2\text{FeCl}_2 + \text{SnCl}_4$$
  
 $2\text{CuCl}_2 + \text{SnCl}_2 \longrightarrow 2\text{CuCl} + \text{SnCl}_4$ 

(c) It decolourises iodine and thus can be titrated with it.

$$SnCl_2 + 2HCl + I_2 \longrightarrow SnCl_4 + 2HI$$

(d) Organic nitro compounds are reduced to amino compounds.

$$C_6H_5NO_2 + 6HCl + 3SnCl_2 \longrightarrow C_6H_5NH_2 + 3SnCl_4+2H_2O$$
Nitrobenzene Aniline

(e) It reduces gold chloride to metallic gold.

$$2AuCl_3 + 3SnCl_2 \longrightarrow \begin{array}{c} 2Au + 3SnCl_4 \\ \text{Colloidal gold} \end{array}$$

SnCl<sub>4</sub> undergoes hydrolysis forming stannic acid which absorbs colloidal particles of gold and thus forms purple of cassius.

Uses: It is used: (i) as a reducing agent.

- (ii) for making purple of cassius. Purple of cassius is used for colouring glass and pottery.
  - (iii) as a mordant in dyeing.

### 4. Stannic Chloride, SnCl<sub>4</sub>

It is prepared by passing dry chlorine over fused tin in a retort. The vapours of stannic chloride are condensed in water cooled receiver.

$$Sn + 2Cl_2 \longrightarrow SnCl_4$$

**Properties:** (i) It is a colourless fuming liquid having disagreeable smell.

- (ii) It is hygroscopic and forms crystalline hydrates containing 3, 5, 6 and 8 molecules of water as water of crystallisation. The pentahydrate SnCl<sub>4</sub>·5H<sub>2</sub>O, is known as "butter of tin" or "oxymuriate of tin".
  - (iii) It is soluble in water in which it undergoes hydrolysis.

$$SnCl_4 + 4H_2O \longrightarrow Sn(OH)_4 + 4HCl$$

It is also soluble in organic solvents showing that it is a covalent compound.

(iv) It dissolves in conc. HCl forming chlorostannic acid. In presence of ammonium chloride, it forms ammonium salt of this acid.

$$SnCl_4 + 2HCl \longrightarrow H_2SnCl_6$$
Chlorostannic acid
 $SnCl_4 + 2NH_4Cl \longrightarrow (NH_4)_2SnCl_6$ 
Ammonium chlorostannate

Uses: It is used:

- (i) in pentahydrate form as a mordant and in ammonium chlorostannate form as a mordant for pink dyes.
  - (ii) for fire-proofing cotton.
  - (iii) for increasing the weight of silk.

## 9.10 LEAD OR PLUMBUM

**Occurrence:** Lead is mainly found in the form of sulphide. The ore is called the galena, PbS. It is usually associated with zinc blende, iron pyrites and traces of silver (up to 0.1 %). The lead content in galena ore varies from 6 to 8%. The other less important ores of lead are:

(a) anglesite,  $PbSO_4$  (b) cerussite,  $PbCO_3$  (c) lanarkite,  $PbO \cdot PbSO_4$ .

**Extraction:** Lead is mainly extracted, from galena ore. The extraction involves the following steps:

- (i) Concentration of the ore
- (ii) Reduction
- (iii) Purification
- (i) Concentration: The ore is crushed and sieved. It is submitted to the froth floatation process for concentration.

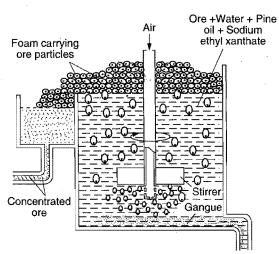

Fig. 9.8 Froth floatation process

The ore is introduced in a large tank containing water to which some pine oil has been added. The mixture is agitated by passing compressed air. The froth is produced which carries away along with it to the surface the ore particles while the gangue settles down at the bottom.

- (ii) Reduction: Two processes are used.
- (a) Air reduction process for ores rich in lead content,
- (b) Carbon reduction process for ores poor in lead content.
- (a) Air reduction process: The concentrated ore is roasted in the reverberatory furnace. The ore is partially oxidised by adjusting the supply of air.

2PbS + 
$$3O_2 \longrightarrow 2$$
PbO +  $2SO_2$   
PbS +  $2O_2 \longrightarrow PbSO_4$ 

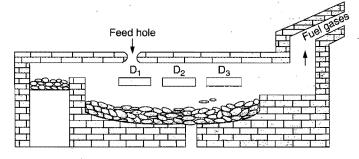

Fig. 9.9 Reverberatory furnace

The temperature of the furnace is raised and air supply is reduced. Some more concentrated galena ore is added. PbS reacts with PbO and PbSO<sub>4</sub> forming lead metal.

$$2PbO + PbS \longrightarrow 3Pb + SO_2$$
  
 $PbSO_4 + PbS \longrightarrow 2Pb + 2SO_2$ 

Thus, roasting and smelting are done in the same furnace at different temperatures.

Molten lead is drawn off from the lower part of the furnace.

(b) Carbon reduction process: The concentrated ore is mixed with some lime and it is then roasted in a sinterer (Fig. 9.10). It is mounted on trunnions for charging and discharging. It is provided with a grating at the bottom and a hood at the top. The air is introduced through grating and is circulated through the charge by applying suction at the top of the hood. PbS oxidised to lead oxide.

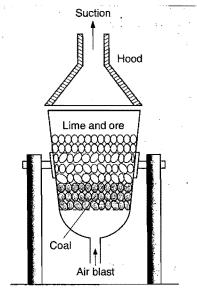

Fig. 9.10 Sinterer

$$2PbS + 3O_2 \longrightarrow 2PbO + 2SO_2$$

Lime serves two purposes:

- (i) It prevents the formation of PbSO<sub>4</sub>.
- (ii) It prevents the formation of PbSiO<sub>3</sub>.

$$[PbSiO_3 + CaO \longrightarrow PbO + CaSiO_3]$$

The sintered ore is crushed into small pieces and mixed with coke and lime. It is fed into a small blast furnace (15–20 feet in height and 3–5 feet in diameter). The following reactions occur in the blast furnace.

$$\begin{array}{c} PbO + C \longrightarrow Pb + CO \\ PbO + CO \longrightarrow Pb + CO_{2} \\ CaO + SiO_{2} \longrightarrow CaSiO_{3} \ (slag) \\ PbSiO_{3} + CaO \longrightarrow PbO + CaSiO_{3} \\ (if \ formed) \end{array}$$

The slag and molten metal are drawn out from the furnace.

(iii) Purification: The lead obtained by any of the above two processes contains Bi, Sb, Cu, Fe, Ag, etc., as impurities.

The removal of these impurities is done by the following processes:

(i) Softening process: This process removes the base metals. The impure metal is melted on the shallow hearth of the reverberatory furnace and a current of air is circulated. The base metals are oxidised and come on the surface of the molten mass as scum which

(ii) Desilverisation: The removal of silver is done by Parke's process or Pattinson's process.

removed.

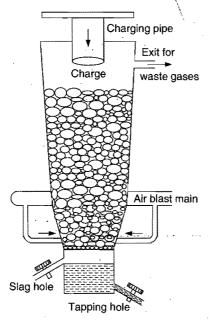

Fig. 9.11 Blast furnace

lead is further purified by Bett's electrolytic method. It consists of impure lead as anode and pure lead as cathode while lead silico fluoride,  $PbSiF_6$ , acts as an electrolyte. This contains 8 to 12% hydrofluosilicic acid  $(H_2SiF_6)$  and a little gelatin.

On passing current, pure lead is deposited on the cathode, the less electropositive impurities like Ag, Au, Sb, etc., collect below anode as anodic mud while more electropositive impurities like Fe, Zn, Ni, etc., go into the solution.

**Properties:** (i) It is a bluish grey metal. It has bright metallic lustre when freshly cut. It is soft in nature and can be cut with knife. It is a heavy metal (sp. gr. 11.35). It melts at 327°C.

- (ii) It leaves a black mark on paper.
- (iii) It is malleable but not ductile.
- (iv) It is poor conductor of electricity.
- (v) It is not attacked by dry air but affected by moist air with the formation of a thin film of basic carbonate on its surface which prevents the further action.
- (vi) When heated in air or oxygen, it forms lead monoxide which changes to red lead.

$$2Pb + O_2 \xrightarrow{\text{Heat}} 2PbO$$
 (Litharge)  
 $6PbO + O_2 \xrightarrow{\text{High temp}} 2Pb_3O_4$  (Red lead)

(vii) It is not affected by pure water except at the boiling point. It dissolves slowly in water containing dissolved oxygen.

$$2Pb + 2H_2O + O_2 \longrightarrow 2Pb(OH)_2$$

The dissolution of lead in water is known as plumbosolvency. The value of plumbosolvency increases if the water contains nitrates, organic acids and ammonium salts. The presence of soluble sulphates, phosphates, carbonates, etc., decrease the dissolution of lead due to formation of a protective thin layer of insoluble lead salts. Lead pipes are often used for conveying drinking water. In order to minimise the dissolution of lead in the form of lead salts which are poisonous, hard water is first passed through lead pipes as to deposit the protective film on the inner surface of the pipes.

(viii) Reaction with acids: Dilute HCl and  $H_2SO_4$  have practically no action on lead. Lead dissolves in hot conc. HCl with evolution of hydrogen.

$$3[Pb + 2HNO_3(dil.) \longrightarrow 2Pb(NO_3)_2 + 2H]$$

$$2[HNO_3 + 3H \longrightarrow NO + 2H_2O]$$

$$3Pb + 8HNO_3(dil.) \longrightarrow 3Pb(NO_3)_2 + 2NO + 4H_2O$$

$$Pb + 2HNO_3(conc.) \longrightarrow Pb(NO_3)_2 + 2H$$

$$2[HNO_3 + H \longrightarrow NO_2 + H_2O]$$

$$Pb + 4HNO_3(conc.) \longrightarrow Pb(NO_3)_2 + 2NO_2 + 2H_2O$$
Organic acids dissolve lead in presence of oxygen.

$$Pb + 2CH_3COOH + \frac{1}{2}O_2 \longrightarrow Pb(CH_3COO)_2 + H_2O$$

Hot conc. H<sub>2</sub>SO<sub>4</sub> dissolves lead with evolution of SO<sub>2</sub> but the reaction becomes slower due to formation of insoluble PbSO<sub>4</sub>.

$$Pb + 2H_2SO_4 \longrightarrow PbSO_4 + SO_2 + 2H_2O$$

HNO<sub>3</sub> is the best solvent for lead. With dil. HNO<sub>3</sub>, NO is evolved while with conc. HNO<sub>3</sub>, NO<sub>2</sub> is liberated.

(ix) Reaction with NaOH: Lead dissolves in NaOH forming sodium plumbite with evolution of hydrogen.

$$Pb + 2NaOH \longrightarrow Na_2PbO_2 + H_2$$

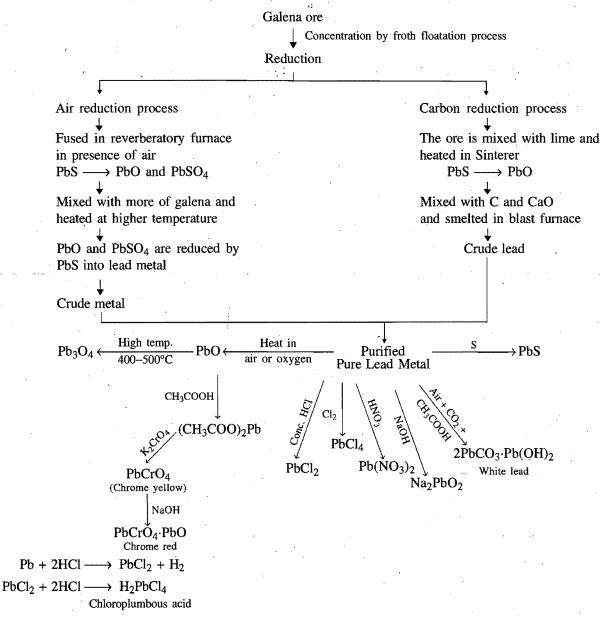

(x) Reaction with non-metals: Lead directly combines with sulphur and halogens.

$$Pb + S \longrightarrow PbS$$
  
 $Pb + 2Cl_2 \longrightarrow PbCl_4$ 

**Uses:** Lead is used:

- (i) for making chambers used in the manufacture of H<sub>2</sub>SO<sub>4</sub>.
- (ii) for making pipes for carrying water.
- (iii) for making telegraph and telephone wires which are to be buried in earth.
  - (iv) in making bullets and lead accumulators.
  - (v) in the preparation of lead pigments.
- (vi) in making useful alloys such as solder, type metal, pewter, etc.

### FLOW SHEET FOR THE EXTRACTION OF LEAD AND FORMATION OF VARIOUS COMPOUNDS

## 9.1 COMPOUNDS OF LEAD

#### 1. Lead Monoxide, PbO

It is known in two forms:

(i) a yellow powder commonly known as massicot and

(ii) a buff coloured crystalline form known as litharge.

**Preparation:** It is obtained by heating lead or lead sulphide in air at 300°C (massicot form). When the temperature of oxidation kept 900, litharge is formed.

$$2Pb + O_2 \longrightarrow 2PbO$$
  
 $2PbS + 3O_2 \longrightarrow 2PbO + 2SO_2$ 

It is also formed by heating lead nitrate or lead carbonate.

$$2Pb(NO_3)_2 \longrightarrow 2PbO + 4NO_2 + O_2$$
  
 $PbCO_3 \longrightarrow PbO + CO_2$ 

**Properties:** It is insoluble in water. It is an amphoteric oxide. It dissolves in acids and alkalies both.

$$PbO + 2HNO_3 \longrightarrow Pb(NO_3)_2 + H_2O$$

$$PbO + 2NaOH \longrightarrow Na_2PbO_2 + H_2O$$

On heating in air at 470°C, it forms red lead.

$$6PbO + O_2 \longrightarrow 2Pb_3O_4$$
 (red lead)

**Uses:** It is used for making glass, paints and varnishes. The mixture of massicot and glycerine is used as a cement for glass and pottery. PbO is used for making other lead compounds.

## 2. Red Lead (Minium or Sindhur), Pb<sub>3</sub>O<sub>4</sub>

**Preparation:** It is obtained by heating litharge at 470°C in air.

$$6PbO + O_2 \xrightarrow{470^{\circ}C} 2Pb_3O_4$$

**Properties:** It is a red powder, insoluble in water. When heated, it becomes almost black but it again becomes red on cooling. On heating above 470°C, it decomposes into PbO and  $O_2$ .

$$2Pb_3O_4 \longrightarrow 6PbO + O_2$$

When treated with conc. HNO3, lead nitrate and brownish black insoluble oxide, PbO<sub>2</sub>, are formed. This indicates that Pb<sub>3</sub>O<sub>4</sub> is a compound oxide containing both PbO<sub>2</sub> and PbO in the ratio of 1:2.

$$Pb_3O_4 + 4HNO_3 \longrightarrow 2Pb(NO_3)_2 + PbO_2 + 2H_2O$$
  
With  $H_2SO_4$ , it evolves oxygen.

$$2Pb_3O_4 + 6H_2SO_4 \longrightarrow 6PbSO_4 + 6H_2O + O_2$$

It acts as an oxidising agent.

$$Pb_3O_4 + 8HCl \longrightarrow 3PbCl_2 + 4H_2O + Cl_2$$
  
 $Pb_3O_4 + 4C \longrightarrow 3Pb + 4CO$   
 $Pb_3O_4 + 4CO \longrightarrow 3Pb + 4CO_2$ 

Uses: It is used:

- (i) as a red pigment.
- (ii) in glass industry.
- (iii) for making protective paint for iron and steel.
- (iv) in match industry as an oxidising agent.

## 3. Lead Acetate (Sugar of Lead), (CH<sub>3</sub>COO)<sub>2</sub>Pb

Preparation: It is prepared by dissolving lead oxide (litharge) or lead carbonate or basic lead carbonate in acetic acid (45%) and crystallising the solution.

PbO + 2CH<sub>3</sub>COOH 
$$\longrightarrow$$
 (CH<sub>3</sub>COO)<sub>2</sub>Pb + H<sub>2</sub>O  
PbCO<sub>3</sub> + 2CH<sub>3</sub>COOH  $\longrightarrow$  (CH<sub>3</sub>COO)<sub>2</sub>Pb + CO<sub>2</sub> + H<sub>2</sub>O  
2PbCO<sub>3</sub> Pb(OH)<sub>2</sub> + 6CH<sub>3</sub>COOH  $\longrightarrow$   
3(CH<sub>3</sub>COO)<sub>2</sub>Pb + 2CO<sub>2</sub> + 4H<sub>2</sub>O

**Properties:** (i) It is a white crystalline solid. It is soluble in water. Its solution has sweet taste and known as sugar of lead but it is poisonous in nature.

(ii) On heating, it decomposes to give acetone.

$$(CH_3COO)_2Pb \longrightarrow PbO + CO_2 + CH_3COCH_3$$
Acetone

(iii) It forms a white precipitate of lead carbonate when treated with sodium bicarbonate.

$$(CH_3COO)_2 \cdot Pb + 2NaHCO_3 \longrightarrow PbCO_3 + 2CH_3COONa + CO_2 + H_2O$$

(iv) It forms a white precipitate of basic lead carbonate when treated with a solution of sodium carbonate.

$$3(CH_3COO)_2Pb + 3Na_2CO_3 + H_2O \longrightarrow$$
  
 $2PbCO_3 \cdot Pb(OH)_2 + 6CH_3COONa + CO_2$   
Basic lead carbonate

(v) A black precipitate is obtained when H<sub>2</sub>S is passed through its solution.

$$(CH_3COO)_2Pb + H_2S \longrightarrow PbS + 2CH_3COOH$$
  
Lead sulphide
(black)

(vi) A yellow precipitate of lead chromate is formed when potassium chromate solution is added.

$$(CH_3COO)_2Pb + K_2CrO_4 \longrightarrow PbCrO_4 + 2CH_3COOK$$

(vii) On addition of dil. HCl to a cold solution of lead acetate, a white precipitate of lead chloride appears. This precipitate is soluble in hot water.

$$(CH_3COO)_2Pb + 2HC1 \longrightarrow PbCl_2 + 2CH_3COOH$$

(viii) The solution of lead acetate on boiling with litharge (PbO) forms basic lead acetate.

$$(CH_3COO)_2Pb + PbO + H_2O \longrightarrow Pb(OH)_2Pb(CH_3COO)_2$$

Basic lead acetate.

**Uses:** It is used:

- (i) in the manufacture of chrome yellow and chrome red employed as lead pigments.
  - (ii) as a mordant in dyeing and calicoprinting.
  - (iii) for the manufacture of white lead.
- (iv) as a laboratory reagent for the test of sulphide and chloride ions.
  - (v) in medicine for curing skin diseases.

## 4. Basic Lead Carbonate (White Lead) 2PbCO<sub>3</sub>·Pb(OH)<sub>2</sub>

White lead is manufactured by the application of the following three methods:

- (i) Dutch process, (ii) Carter's process, (iii) Electrolytic process.
- 1. Dutch process: This is the oldest method but it produces the best quality of white lead. It is a very slow method and takes about 6 to 8 weeks for the conversion of lead metal into white lead in the presence of acetic acid, carbon dioxide and moist air.

Lead is melted and cast into the form of perforated discs, called buckles. A number of earthenware pots with shelves are taken in which vinegar or dilute acetic acid (3%) is placed at their bottom. Buckles are kept at the shelves of these earthenware pots. These pots are then arranged in rows. These are partly covered with wooden planks and the space in between the rows is fled by spent tanbark and horse dung (Fig. 9.12).

The pots are allowed to remain in this position for about 6 to 8 weeks. During this period, fermentation of tanbark and horse dung occurs. This produces CO2 and heat energy which helps in the evaporation of acetic acid. The combined action of acetic acid vapours, carbon dioxide, air and moisture converts lead into white lead. The following chemical changes are supposed to take place.

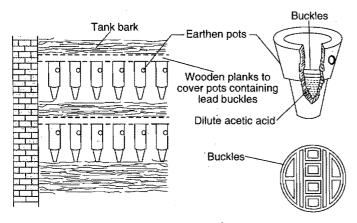

Fig. 9.12 Dutch process

$$\begin{aligned} & 2\text{Pb} + 2\text{H}_2\text{O} + \text{O}_2 \longrightarrow 2\text{Pb}(\text{OH})_2 \\ & \text{Pb}(\text{OH})_2 + 2\text{CH}_3\text{COOH} \longrightarrow \text{Pb}(\text{CH}_3\text{COO})_2 + 2\text{H}_2\text{O} \\ & \text{Pb}(\text{OH})_2 + \text{Pb}(\text{CH}_3\text{COO})_2 \longrightarrow \text{Pb}(\text{CH}_3\text{COO})_2 \cdot \text{Pb}(\text{OH})_2 \\ & \text{Basic lead acetate} \\ & 3[\text{Pb}(\text{CH}_3\text{COO})_2 \cdot \text{Pb}(\text{OH})_2] + 4\text{CO}_2 + 2\text{H}_2\text{O} \longrightarrow \end{aligned}$$

. 
$$2[2PbCO_3 \cdot Pb(OH)_2] + 6CH_3COOH$$
  
White lead

White lead is removed from unchanged lead and washed with water to remove soluble lead acetate. It is then dried.

**2.** Carter's process: It is comparatively quicker process. This process is carried in wooden cylinders which are rotated.

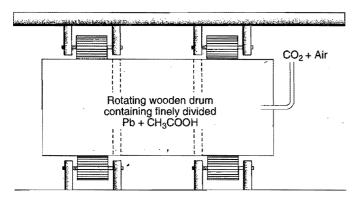

Fig. 9.13 Carter's process

Molten lead is first atomised by a jet of superheated steam or compressed air and brought in the wooden cylinders. A spray of acetic acid, carbon dioxide and air is blown into the cylinders (Fig. 9.13).

The same chemical changes occur as in the Dutch process. The conversion takes place in 5–12 days.

**3. Electrolytic process:** The electrolytic cell is divided into two compartments with the help of a porous diaphragm. The anodic compartment is filled with sodium acetate solution and contains anodes of lead plates, while cathodic compartment consists of cathodes of steel dipped into a solution of sodium carbonate. On passing electricity, lead of anode starts dissolving in the form of lead acetate, which meets with sodium carbonate to form white lead.

$$CH_{3}COONa \Longrightarrow CH_{3}COO^{-} + Na^{+}$$

$$Anode$$

$$dissolves lead$$

$$Pb(CH_{3}COO)_{2}$$

$$3Pb(CH_{3}COO)_{2} + 4Na_{2}CO_{3} + 2H_{2}O \longrightarrow$$

$$2PbCO_{3} \cdot Pb(OH)_{2} + 2NaHCO_{3} + 6CH_{3}COONa$$

White lead is washed with water and dried.

**Properties:** It is white, heavy amorphous powder. It is insoluble in water. It is poisonous in nature. It is miscible with linseed oil. On heating to 430°C, it decomposes into red lead.

$$\begin{array}{c} \text{2PbCO}_3 \cdot \text{Pb(OH)}_2 \longrightarrow \begin{array}{c} \text{Pb}_3 \text{O}_4 + \text{H}_2 \text{O} + \text{CO} + \text{CO}_2 \\ \text{Red lead} \end{array}$$

It is darkened in air due to formation of PbS.

**Uses:** White lead mixed with linseed oil is used as a white paint. It has a large covering power. It is generally mixed with BaSO<sub>4</sub> which increases its property of brushing out without affecting its covering power.

The main drawbacks to the use of white lead are that it becomes black if H<sub>2</sub>S is present in atmosphere and it is poisonous in nature. Various substitutes such as lithopone, titanium dioxide, sublimed white lead, etc., have been suggested. It is also used for the preparation of red lead and pottery glazes.

## SOME SOLVED PROBLEMS

**Example 1.** A colourless solution contains a metal nitrate. A little solution of sodium chloride is added to it when a cloudy white precipitate appears. How you will ascertain about the metal ion?

#### **Solution:**

The chloride ions have combined with the metal ions to give the precipitate of a chloride as sodium nitrate is soluble.

Metal nitrate + NaCl 
$$\longrightarrow$$
 Metal chloride + NaNO<sub>3</sub> (Insoluble) (Soluble)

The metal chloride may be PbCl<sub>2</sub> or AgCl or Hg<sub>2</sub>Cl<sub>2</sub>. The following tests can be used to ascertain the metal chloride.

- (i) If the precipitate dissolves in hot water, it is PbCl<sub>2</sub>.
- (ii) If the precipitate dissolves in NH<sub>4</sub>OH, it is AgCl.
- (iii) If the precipitate turns black with NH<sub>4</sub>OH, it is Hg<sub>2</sub>Cl<sub>2</sub>.

**Example 2.** (a) If you have to dissolve lead (II) oxide, PbO, which acid you will choose?

(b) Explain why the reactions with hydrochloric acid and sulphur dioxide show the oxidising nature of  $PbO_2$ .

(c) Predict the result of reacting Pb<sub>3</sub>O<sub>4</sub> with concentrated hydrochloric acid. [M.L.N.R. 1992]

#### **Solution:**

(a) Nitric acid. This is because lead nitrate formed is soluble in water. If H<sub>2</sub>SO<sub>4</sub> is used, an insoluble layer of PbSO<sub>4</sub> is deposited on the surface of powder and prevents the further reaction. Likewise, PbCl<sub>2</sub> prevents the reaction with HCl.

$$\begin{array}{ccc} & \text{IV} & \text{II} \\ & \text{PbO}_2 + 4\text{HCI} \longrightarrow & \text{PbCl}_2 + \text{Cl}_2 + 2\text{H}_2\text{O} \\ & \text{IV} & \text{II} \\ & \text{PbO}_2 + \text{SO}_2 & \longrightarrow & \text{PbSO}_4 \end{array}$$

In above reactions, lead changes from lead (IV) to lead (II), *i.e.*, gain of electrons.

$$Pb^{4+} + 2e \longrightarrow Pb^{2+}$$

Thus, PbO<sub>2</sub> acts as oxidising agent as it oxidises HCl and SO<sub>2</sub>

(c) Pb<sub>3</sub>O<sub>4</sub> is considered to possess PbO and PbO<sub>2</sub>· PbO<sub>2</sub> acts as an oxidising agent. Thus, PbCl<sub>2</sub> and Cl<sub>2</sub> are formed.

$$Pb_{3}O_{4} \longrightarrow 3PbO + O$$

$$2HCl + O \longrightarrow H_{2}O + Cl_{2}$$

$$[PbO + 2HCl \longrightarrow PbCl_{2} + H_{2}O] \times 3$$

$$Pb_{3}O_{4} + 8HCl \longrightarrow 3PbCl_{2} + Cl_{2} + 4H_{2}O$$

## **Example 3.** Explain the following:

- (i) The first ionisation energy of carbon atom is greater than that of boron atom whereas the reverse is true for second ionisation energy.
  - (ii)  $(SiH_3)_3N$  is a weaker base than  $(CH_3)_3N$ . [I.I.T. 1995]
  - (iii) Diamond is very hard while graphite is soft.

[I.I.T. 1993]

- (iv)  $CO_2$  is a gas while silica is a solid.
- (v) Solid carbon dioxide is known as dry ice.

#### **Solution:**

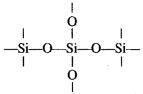

(i) The first ionisation energy of carbon  $(1s^2, 2s^2 2p_x^{-1}2p_y^{-1})$  is higher than boron  $(1s^2, 2s^22p_x^{-1})$  as the nuclear charge in carbon is higher than boron (At. no. C = 6; B = 5).

The second ionisation energy of carbon is less than that of boron because in carbon the second electron is to remove from 2p-orbital while in boron the second electron is to be removed from paired 2s-orbital which requires higher energy in comparison to singly occupied p-orbital.

- (ii) In  $(SiH_3)_3 N$ , the lone pair of electrons on nitrogen is involved in  $p\pi$ — $d\pi$  back bonding, while such bonding is not possible in  $(CH_3)_3 N$ , as d-orbitals are not present in carbon. Hence, the lone pair of electrons on nitrogen in  $(CH_3)_3 N$  is available for donation to Lewis acids, thereby acting as stronger base.
- (iii) Diamond has giant three dimensional polymeric structure in which each carbon is  $sp^3$  hybridized and linked to four carbon atoms. This structure makes diamond as hardest. On

account of small radii of carbon atoms, the various atoms are closely packed in the crystal lattice. Graphite possesses layer structure in which each carbon atom is  $sp^2$  hybridized. There is wide separation between various layers. One layer can slide easily on the other. This makes graphite soft in nature.

(iv) In carbon dioxide discrete molecules are present. In each molecule carbon is linked with two oxygen atoms by double bonds (O=C=O), while silica possesses a giant three dimensional structure in which each silicon is linked with four oxygen atoms tetrahedrally and each oxygen is linked with two silicon atoms.

This structure is extremely stable and considerable energyis required to break Si—O bond. Thus, CO<sub>2</sub> is a gas and silica is a solid.

(v) When solid  $CO_2$  evaporates, it changes to the gaseous state without coming to the liquid state. It produces cooling during evaporation. It is, therefore, known as dry ice.

**Example 4.** Write the formulae of the following compounds:

(a) Butter of tin

(b) White lead

(c) Red lead

(d) Sugar of lead

(e) Litharge

(f) Carborundum

(g) Phosgene

(h) Chrome yellow

(i) Water glass

(j) Drykold

#### **Solution:**

(a) SnCl<sub>4</sub>·5H<sub>2</sub>O

(Stannic chloride)

(b) 2PbCO<sub>3</sub>·Pb(OH)<sub>2</sub>

(Basic lead carbonate)

(c) Pb<sub>3</sub>O<sub>4</sub>

(Trilead tetra-oxide)

(d) Pb(CH<sub>3</sub>COO)<sub>2</sub>

(Lead acetate)

(e) PbO

(Lead monoxide)

(f) SiC

(Silicon carbide)

(g) COCl<sub>2</sub>

(Carbonyl chloride)

(h). PbCrO<sub>4</sub>

Tand alamanaka)

(11): 1 - - - - - 4

(Lead chromate)

(i) Na<sub>2</sub>SiO<sub>3</sub>

(Sodium silicate)

(j) CO<sub>2</sub>

(Carbon dioxide in solid state)

**Example 5.** An aqueous solution of a salt (A) gives a white precipitate (B) with sodium chloride solution. The filtrate gives a black precipitate (C) when  $H_2S$  is passed into it. Compound (B) dissolves in hot water and the solution gives a yellow precipitate (D) on treatment with sodium iodide. The compound (A) does not give any gas with dilute HCl but liberates a reddish brown gas on heating. Identify the compounds (A) to (D).

#### **Solution:**

Since the crystalline compound (B) dissolves in hot water

and gives a yellow precipitate with NaI, it should be lead chloride, PbCl<sub>2</sub> and the solution (A) consists a lead salt.

$$PbCl_2 + 2NaI \longrightarrow PbI_2 + 2NaCl$$
<sub>(B)</sub>
<sub>(D)</sub>

The compound (A) does not give any gas with dilute HCl but liberates a reddish brown gas on heating, it should be lead nitrate,  $Pb(NO_3)_2$ .

$$\begin{array}{ccc} 2Pb(NO_3)_2 & \longrightarrow & 2PbO + 2NO_2 + O_2 \\ (A) & & \text{Reddish brown gas} \end{array}$$

Lead chloride is sparingly soluble in water. When H<sub>2</sub>S is passed, it gives a black precipitate of lead sulphide, PbS.

$$PbCl_2 + H_2S \longrightarrow PbS + 2HCl$$
Black
(C)

Thus,

- (A) is lead nitrate,  $Pb(NO_3)_2$ ,
- (B) is lead chloride, PbCl<sub>2</sub>,
- (C) is lead sulphide, PbS,

and

(D) is lead iodide, PbI<sub>2</sub>.

**Example 6.** (i) Indicate the principal ingredients of the following:

- (a) Coal gas (b) Producer gas (c) Water gas. [M.L.N.R.1991]
- (ii) Identify A and B (compound/reaction condition):

$$PbS \xrightarrow{Heat} A + PbS \xrightarrow{B} Pb + SO_2$$
 [1.1.T. 1991]

#### Solution:

- (i) Coal gas,  $H_2 + CH_4 + CO$ Producer gas,  $CO + N_2$ Water gas,  $CO + H_2$
- (ii) A = PbO or  $\text{PbSO}_4$  B = high temperatureAir supply is cut off.

**Example 7.** Write the balanced equation for reaction of  $Al_4C_3$  and CaNCN with water. [I.I.T. 2002]

#### **Solution:**

$$Al_4C_3 + 12H_2O \longrightarrow 4Al(OH)_3 + 3CH_4$$
.  
 $CaNCN + 3H_2O \longrightarrow CaCO_3 + 2NH_3$ .

**Example 8.** Like CO why its analogue SiO is not stable? [C.B.S.E. (P.M.T.) 2004]

#### **Solution:**

Carbon has a strong tendency to form  $p\pi-p\pi$  multiple bonds due to its small size and high electronegativity. Carbon combines with oxygen and forms stable CO forming  $p\pi-p\pi$  multiple bonds. CO is actually a resonance hybrid of the following two structures:

$$:C = 0: \longleftrightarrow :C = 0:$$

Silicon, on the other hand, on account of its bigger size and lower electronegativity has no tendency to form  $p\pi-p\pi$  multiple bonds and thus does not combine with oxygen to form stable SiO.

**Example 9.**  $[SiF_6]^{2-}$  is known whereas  $[SiCl_6]^{2-}$  not. Give possible reasons.

#### **Solution:**

The possible reasons for the non-existence of  $[SiCl_6]^{2-}$  are:

- (i) due to large size of Cl atoms. Six fluorine atoms can be easily accommodated around silicon atom due to smaller size while six larger chlorine atoms cannot be accommodated around silicon atom.
- (ii) due to the presence of lone pair of electrons in fluorine atom on a smaller 2p-orbital, the interaction with d-orbital of silicon atom is stronger rather than the presence of lone pair of electrons in chlorine atom on a larger 2p-orbital, the interaction with d-orbital of silicon atom is poor.

**Example 10.** (a) Why Sn(II) is a reducing agent whereas Pb(II) is not?

- (b) Why does not silicon form an analogue of graphite?
- (c) C and Si are always tetravalent but Ge, Sn and Pb show divalency. Why?

#### **Solution:**

(a) Both Sn and Pb exhibit +2 and +4 oxidation states due to inert pair effect. Inert pair effect is more effective in lead than in tin. Thus, +2 state is less stable in tin and thus, Sn(II) acts as a reducing agent and converted into more stable Sn(IV) state. For example, Fe<sup>3+</sup> is reduced by Sn(II).

$$2Fe^{3+} + Sn^{2+} \longrightarrow 2Fe^{2+} + Sn^{4+}$$

- (b) On account of bigger size and smaller electronegativity of silicon atom in comparison to carbon atom, silicon atom does not undergo  $sp^2$ -hybridization and does not form  $p\pi$ - $p\pi$  double bonds. Thus, silicon does not form graphite like structure as it requires double bonds:
- (c) Carbon and silicon have no d- or f-electrons in inner shells. Therefore, they do not show inert pair effect. Consequently, they show only tetravalency due to  $sp^3$  hybridization. In all other elements from Ge to Pb either d- or both d- and f-electrons are present. Due to poor shielding effect, inert pair effect is observed, i.e., showing either divalency or tetravalency. The stability of divalency increases while that of tetravalency decreases as the inert pair effect becomes more and more prominent from Ge to Pb.

**Example 11.** (a) Silica is attacked by hydrofluoric acid with the formation of  $SiF_6^{2-}$  anions. The analogous  $CF_6^{2-}$  anion does not exist. Account for this.

(b) Diamond is covalent, yet it has a high melting point. Why? **Solution:** 

(a) Silicon has 3d-orbitals in the valence shell and thus expands its octet giving  $sp^3d^2$ -hybridization while d-orbitals are not present in the valence shell of carbon. It can undergo  $sp^3$ -hybridization only. Thus, carbon is unable to form  $CF_6^{2-}$  anion.

- (b) Diamond has three dimensional network involving strong C—C bonds which are difficult to break. Hence, its a high melting point.
- **Example 12.** (a) Discuss briefly why tin and lead compounds do not show  $p\pi$ - $p\pi$  bonding?
- (b) What are the properties responsible for the anomalous behaviour of carbon?
  - (c) Which silicon compound is used as a:
  - (i) dehydrating agent
- (ii) cation exchanger
- (iii) lubricant
- (iv) thermal insulator.

#### **Solution:**

- (a) Tin and lead do not show  $p\pi-p\pi$  bonding because the *d*-orbitals of Sn and Pb are of much higher energy than that of the element with which they form a bond in the compound.
- (b) Small size, high electronegativity, high ionisation energy and absence of *d*-orbitals in the valence shell are the main properties of carbon which lead to its anomalous behaviour.
  - (c) (i) Silica gel
- (ii) Zeolites
- (iii) Silicones
- (iv) Asbestos

## SUMMARY AND IMPORTANT POINTS TO REMEMBER

1. Group IVA or 14 of the periodic table consists of six elements—carbon, silicon, germanium, tin, lead and ununquadium. These are p-block elements as the last differentiating electron is accommodated in np-shell. These elements have four electrons in their valency shell, two of which are in s-orbital while remaining two in p-orbitals, i.e., ns<sup>2</sup>np<sup>2</sup> configuration.

- 2. Carbon is seventeenth and silicon is second most abundant element by mass in earth's crust. Carbon is found both in native and combined state. Carbon is an essential constituent of all living matter as proteins, carbohydrates and fats. Silicon occurs very widely as silica and a wide variety of silicate minerals and clays. Tin and lead are comparatively low but are found as concentrated ores. The important ore of tin is cassiterite (SnO<sub>2</sub>) and that of lead is galena (PbS). Germanium is rare element.
- 3. (a) Non-metallic nature decreases from carbon to lead.

C Si

Ge Metalloid Sn Pb Metals

- (b) Density increases from C to Pb.
- (c) Melting and boiling points decrease down the group.
- (d) Atomic radii increase on moving down the group.
- (e) Electronegativity decreases from C to Si.
- (f) Ionisation energy decreases regularly from C to Sn. Pb, however, shows a higher value than Sn due to poor shielding of *f*-orbitals.
- **4.** All the elements show tetravalency due to  $sp^3$  hybridization. Last three members show inert pair effect and show the tendency to form  $M^{2+}$  ions. The stability of  $M^{2+}$  state increases as the atomic number increases. The compounds of  $Ge^{2+}$  and  $Sn^{2+}$  are less stable than  $M^{4+}$  state. Thus,  $Ge^{2+}$  and  $Sn^{2+}$  compounds act as **reducing agents**.

  Ph<sup>2+</sup> compounds are more stable than  $Ph^{4+}$  compounds
  - Pb<sup>2+</sup> compounds are more stable than Pb<sup>4+</sup> compounds. Thus, Pb<sup>4+</sup> compounds act as oxidising agents.
- 5. The tendency of formation of long open or closed chains by the combination of same atoms in themselves is known as catenation. This property is maximum in carbon and decreases down the group. Lead shows no catenation.

Only carbon atoms do form double or triple bonds involving  $p\pi$ – $p\pi$  bonding. Carbon has also the property to form closed chain compounds with O, S and N atoms as well as forming  $p\pi$ – $p\pi$  multiple bonds with other elements particularly N, S and O. Carbon can form chains containing as many as carbon atoms but Si and Ge cannot extend the chain beyond 6 atoms. The reason for greater tendency of carbon for catenation is due to high bond energy between carbon and carbon atoms. This bond energy is approximately of the same magnitude as the energies of the bond between carbon and atoms of other elements.

C-C (83 kcal mol<sup>-1</sup>); C-O (86 kcal mol<sup>-1</sup>);

C— $Cl(81 kcal mol^{-1})$ 

- **6.** The maximum covalency of carbon is four because it has no *d*-orbitals which can be used to accommodate more than 8 electrons.
  - Remaining elements have vacant d-orbitals. Thus, they have the tendency to show maximum covalency of six involving  $sp^3d^2$ -orbitals.
- 7. The phenomenon of existence of a chemical element to exist in two or more forms differing in physical properties but having almost same chemical nature is known as allotropy. This phenomenon is due to the difference either in the number of atoms in the molecules or arrangement of atoms in the molecules in the crystal structure. Except lead, all other members of group 14 exhibit allotropy.
  - Carbon exists as diamond, graphite, coal, charcoal, lampblack and fullerene. Silicon exists in two forms, crystalline and amorphous; germanium exists in two crystalline forms and tin exists in three forms; grey, white and rhombic form.
- **8.** Diamond is the purest form of carbon. It is the crystalline form. It is the hardest natural substance known. It is bad conductor of electricity and heat. It is transparent to X-rays and glows in ultraviolet rays. It has high refractive index (2.45). It is chemically inert. It reacts with fluorine at 700°C to form CF<sub>4</sub>. In diamond every carbon is in  $sp^3$  hybridized state and linked to four other carbon atoms tetrahedrally by covalent bonds. It is, thus, a giant three dimensional polymeric structure in which C—C distance is 1.54 Å and bond angle 109.5°. It is used as gem stone and in knifes for cutting glasses and rock borers.

- 9. Graphite is another crystalline form of carbon. It is found in nature and is also manufactured by Acheson process. It is soft, greasy, dark greyish coloured crystalline solid. It is good conductor of electricity. It leaves a black mark on paper and is called black lead or plumbago. It is chemically more active than diamond. With alkaline KMnO<sub>4</sub>, it is oxidised to mellitic acid [C<sub>6</sub>(COOH)<sub>6</sub>] and oxalic acid. Conc. HNO<sub>3</sub> or conc. H<sub>2</sub>SO<sub>4</sub> oxidises it into insoluble yellowish green substance, known as graphitic acid C<sub>11</sub>H<sub>4</sub>O<sub>5</sub>.
  - It has two dimensional sheet structure. Each carbon is  $sp^2$  hybridized and is linked to three carbon atoms in hexagonal planar structure. The C—C bond distance is 1.42 Å. The adjacent layers are held by van der Waals' forces and distance between layers is 3.4Å. Graphite is thermodynamically more stable form.
  - It is used for lining and making electrodes, refractory crucibles, lead pencils. It acts as a moderator in nuclear reactor. It is also used as a lubricant in machinery.
- 10. An allotropic form called fullerenes or Buckminster-fullerenes or Bucky balls recently discovered is C<sub>60</sub> or C<sub>70</sub>. Such molecules are made from interlocking hexagonal and pentagonal rings of carbon atoms and exist in chimney soot or candle smoke.
- 11. Carbon has three amorphous forms. These are coal, charcoal and lampblack. Coal is the crude form of carbon. It is found in various forms depending upon the carbon content (peat, lignite, bituminous, steam coal and anthracite). Anthracite is the superior quality of coal.
  - When coal is subjected to destructive distillation, it loses volatile constituents and the residue left is known as **coke**. Coal is used as a fuel, for making fuel gases and synthetic petrol and coke.
  - Charcoal is formed when wood, cellulose or any other carboneous matter are burnt in limited supply of air. This is the most active form. It has number of applications.
  - Lampblack, carbon black or soot is obtained by burning substances rich in carbon such as kerosene, turpentine oil, etc., in a limited supply of air. These substances yield a large amount of smoke which is passed into chambers having wet blankets. The soot collected on blankets is called lampblack. It is almost pure carbon. It is a soft black powder and is used as a pigment in black inks and paints. It is also used as a filler in making rubber tyres.
- 12. The elements of group 14 react with oxygen on strong heating to form oxides of the type  $MO_2$ . The acidic nature decreases with increase in atomic number.  $CO_2$  and  $SiO_2$  are acidic while  $GeO_2$ ,  $SnO_2$  and  $PbO_2$  are amphoteric in nature. They dissolve in alkalies forming carbonates, silicates, germanates, stannates and plumbates of the type  $Na_2MO_3$  respectively.
  - They also form oxides of the type MO.SiO is unstable. CO is neutral while SnO and PbO are amphoteric.
- 13. Non-oxidising acids do not attack carbon and silicon. Tin dissolves slowly in dilute HCl but readily in conc. HCl. Lead also dissolves in HCl forming insoluble PbCl<sub>2</sub>. Germanium is not attacked by dilute HCl but when metal is heated in a

- stream of HCl gas, germanium chloroform (GeHCl<sub>3</sub>) is formed. Concentrated H<sub>2</sub>SO<sub>4</sub> and HNO<sub>3</sub> attack Ge, Sn and Pb.
- **14.** Except carbon, all other members of group 14 dissolve in aqueous NaOH solution evolved hydrogen.

$$M + 2$$
NaOH + H<sub>2</sub>O  $\longrightarrow$  Na<sub>2</sub> $M$ O<sub>3</sub> + 2H<sub>2</sub>

- **15.** All the members of group 14 form covalent hydrides of type  $MH_4$ . Besides  $CH_4$ , carbon forms a large number of hydrides, saturated and unsaturated. Silicon forms only limited number of saturated hydrides. Germanium gives a still smaller number while Sn and Pb form only one hydride each. Hydrides are gaseous and their thermal stability decreases and consequently reducing nature increases.
- **16.** All the members of group 14 form tetrahalides of the type  $MX_4$  except PbBr<sub>4</sub> and PbI<sub>4</sub>. The halides are covalent and formed by  $sp^3$  hybridization. The thermal stability decreases.

 $CX_4 > SiX_4 > GeX_4 > SnX_4 > PbX_4$ Except carbon halides, other halides are readily hydrolysed by water. The hydrolysis is due to utilization of *d*-orbitals. The tetrahalides of Si, Ge, Sn and Pb can form hexahalo complexes. The tetrahalides of Si, Ge, Sn and Pb act as strong Lewis acids.

- 17. CO is a colourless, odourless, poisonous and neutral oxide. It is slightly soluble in water. It is obtained by heating K<sub>4</sub>Fe(CN)<sub>6</sub> with conc. H<sub>2</sub>SO<sub>4</sub>. It is absorbed by ammonical Cu<sub>2</sub>Cl<sub>2</sub> solution. It is combustible but does not support combustion. Its poisonous nature is due to its reaction with haemoglobin to form carboxy-haemoglobin which is not capable of absorbing oxygen. It is a good reducing agent. The bonding in CO is represented as: C ⊆ O. It acts as a π-acid ligand. It forms addition compound with a number of substances. It combines with metals like Ni, Cr, Fe, etc. The compounds formed are called carbonyls.
  - It is used as a fuel in the form of water gas, producer gas, etc. It is used in the manufacture of methanol, synthetic petrol, formic acid, phosgene gas, etc. It is used as a reducing agent in extraction of iron and in Mond's process for extraction of Ni.
- 18. CO<sub>2</sub> is a colourless, odourless and tasteless gas. It is present in atmosphere. It is slightly soluble in water but more soluble under pressure. It is heavier than air. It is easily liquefied under pressure into a colourless mobile liquid. If CO<sub>2</sub> under pressure is allowed to escape through a nozzle, a white solid, i.e., dry ice is obtained. Solid CO<sub>2</sub> is soft, white, snow like substance. It sublimes and leaves no residue. Solid CO<sub>2</sub> is used as a refrigerant under the commercial name drikold.

It is neither combustible nor a supporter of combustion. However, burning magnesium, sodium or potassium continues burning in the gas.  $CO_2$  is converted by plants into glucose and higher carbohydrates in the presence of sunlight and chlorophyll. This process is known as **photosynthesis**. **Carbogen** is a mixture of  $O_2$  and  $CO_2$  (5 to 10%). It is used for artificial respiration.

A mixture of solid  $CO_2$  and ether is used to produce low temperature of the order of  $-80^{\circ}$ C to  $-100^{\circ}$ C.  $CO_2$  is used as a fire extinguisher.

- (a) Dry powder extinguishers contain sand and baking soda (NaHCO<sub>3</sub>).
- (b) Baking soda and sulphuric acid type extinguishers.
- (c) Foamite extinguishers contain baking soda and aluminium sulphate.
- 19. The carbides are binary compounds in which carbon combines with elements of lower or about equal electronegativity. Carbides are divided into three categories.
  - (i) Salt-like or ionic or electrovalent carbides: These are formed by strong electropositive elements of group 1, 2 and 13 (except boron), coinage metals, Zn, Cd and some lanthanides. These are further classified into three classes:
    - (a) Methanides: These give methane on hydrolysis. They contain  $C^{4-}$  ions, e.g., Be<sub>2</sub>C, Al<sub>4</sub>C<sub>3</sub>.
    - (b) Acetylides: These give acetylene on hydrolysis. They contain  $C_2^{2-}(C \equiv C)^{2-}$  ions, e.g.,  $CaC_2$ ,  $BeC_2$ ,  $Li_2C_2$ ,  $Na_2C_2$ , etc.
    - (c) Allylides: These give propyne or allylene on hydrolysis. These contain  $C_3^4$  ion, e.g.,  $Mg_2C_3$ .
  - (ii) Covalent carbides: Boron carbide and carborundum (SiC) belong to this category. They are covalent, polymeric, thermally stable, extremely hard, high melting and inert solids. SiC has diamond like structure.
  - (iii) Metallic or interstitial carbides: These are formed by transitional elements. Carbon atoms being small in size occupy interstitial positions of metal atoms. These carbides are hard and possess high melting points, used as refractory materials.
- **20.** Water gas, producer gas, coal gas, oil gas, natural gas, LPG, etc., are gaseous fuels. These have high calorific values.
  - (i) Water gas or synthetic gas is a mixture of CO and H<sub>2</sub>. It is made by passing steam over red hot coal at 1000 − 1400°C.
  - (ii) Producer gas is a mixture of CO and N<sub>2</sub>. It is made by passing air on hot coke. It has lower calorific value than water gas.
  - (iii) Coal gas is a mixture of hydrogen, methane, carbon monoxide, acetylene, etc. It is obtained by destructive distillation of coal at 1000°C. It has high calorific value.
  - (iv) Oil gas is obtained by cracking of kerosene. It is a mixture of lower hydrocarbons.
  - (v) Natural gas mainly contains CH<sub>4</sub>.
  - (vi) LPG is a mixture of butane and isobutane.
  - (vii) Semiwater gas is a mixture of water gas and producer gas.
- 21. Silicon is the second most abundant element in the earth's crust (about 28% by mass). Unlike carbon, it is never found in free state but always in combined state. Silicon is widely present as silica (SiO<sub>2</sub>) in various forms such as sand, quartz, flint, etc. Silicon exists in two forms (a) amorphous and (b) crystalline. The amorphous variety is obtained by heating dry powdered silica with magnesium. The crystalline form is obtained by heating finely powdered sand or quartz with carbon in an electric furnace.

- Amorphous silicon is chemically more active than crystalline silicon.
- 22. Sodium silicate is commercially called water glass. It is chemically sodium metasilicate containing an excess of silica. Its composition varies from Na<sub>2</sub>SiO<sub>3</sub>·SiO<sub>2</sub> to Na<sub>2</sub>SiO<sub>3</sub>·3SiO<sub>2</sub>. It is soluble in water and its solution is alkaline. Some coloured salts like cobalt nitrate, nickel chloride, ferrous sulphate, copper sulphate, etc., are placed in the solution of sodium silicate and whole solution is left as such for a night. A beautiful hollow tubes of metallic silicate gels possessing colours shoot up from these crystals and look like plants. This is called **silica garden**.
- 23. Silicones are organosilicon polymers containing Si—O—Si linkages. These are formed by the hydrolysis of alkyl or aryl substituted chlorosilanes and their subsequent polymerization. The substituted chlorosilanes are formed by the reaction of Grignard reagents and silicon tetrachloride.

 $RMgCl + SiCl_4 \longrightarrow R \longrightarrow SiCl_3$  or  $R_2SiCl_2$  or  $R_3SiCl$ .  $R_2SiCl_2 \stackrel{HOH}{\longrightarrow} R_2Si(OH)_2 \longrightarrow HO \longrightarrow Si(R_2) \longrightarrow O\longrightarrow Si(R_2) \longrightarrow OH$ Polymerization continues on both ends and thus chain increases in length (linear thermoplastic polymer)  $RSiCl_3 \stackrel{HOH}{\longrightarrow} RSi(OH)_3$ . This gives crossed linear silicone. Lower silicones are oily liquids while higher members containing long chains or ring structures are waxy and rubber like solids. These are stable towards heat and chemical reagents and are good electrical insulators. These are nontoxic and are water repellents. These have variety of industrial applications.

- **24.** Silicates are metal derivatives of silicic acid, H<sub>4</sub>SiO<sub>4</sub> or Si(OH)<sub>4</sub>. Silicates are formed by heating metal oxides or carbonates with sand. Silicates have basic unit SiO<sub>4</sub><sup>4</sup>. Each silicon atom is tetrahedrally bonded to four oxide ions.
  - (i) Orthosilicates Contain single discrete unit of SiO<sub>4</sub><sup>4</sup>-tetrahedra, e.g., zircon (ZrSiO<sub>4</sub>).
  - (ii) Pyrosilicates Contain two units of SiO<sub>4</sub><sup>4</sup> joined along a corner containing oxygen. Pyrosilicate ion, Si<sub>2</sub>O<sub>7</sub><sup>6</sup>, e.g., thorteveitite Sc<sub>2</sub>Si<sub>2</sub>O<sub>7</sub>.
  - (iii) Cyclic or ring silicates General formula  $(SiO_3^2)_n$ , e.g., beryl Be<sub>3</sub>Al<sub>2</sub>Si<sub>6</sub>O<sub>18</sub>.
  - (iv) Chain silicates By sharing two oxygen atoms of each tetrahedra.
  - (v) Two dimensional sheet silicates By sharing three oxygen atoms of each tetrahedra. General formula  $(Si_2O_5)_n^{2n-}$ .
  - (vi) Three dimensional sheet silicates Involve all the four oxygen atoms of each tetrahedra examples quartz, tridymite, feldspar, ultramarines, etc.
- 25. Glass is a transparent or translucent super cooled solid solution of silicates and borates. The most common silicates are those of sodium, potassium, calcium and lead. An approximate formula is R<sub>2</sub>O<sub>2</sub>MO<sub>2</sub>6SiO<sub>2</sub>, where R = Na or K and M = Ca, Ba, Zn or Pb. SiO<sub>2</sub> may be replaced by Al<sub>2</sub>O<sub>3</sub>, B<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>.
- **26.** Glass is attacked by HF. This property is used in the etching of glass.

- 27. The most important ore of tin is cassiterite, SnO<sub>2</sub>. The ore is crushed and powdered. It is washed with running water to remove lighter siliceous matter. Iron tungstate is removed by electromagnetic separator. The ore is now roasted to remove sulphur and arsenic. The roasted mass is mixed with about one fifth of its mass with anthracite (carbon) and subjected to heat in a reverberatory furnace. The liquid metal is drawn off from the furnace. It is further purified by liquation and poling.
- **28.** (a) Tin produces a peculiar sound whenever it is bent. The cracking sound is known as **Tincry.** 
  - (b) It exists in three allotropic forms. White tin is the common and most stable.

Grey tin 
$$\frac{18^{\circ}\text{C}_{\searrow}}{\checkmark}$$
 White  $\frac{170^{\circ}\text{C}}{\checkmark}$  Rhombic

The conversion of white tin to grey tin in cold countries is accompanied by decrease in density, comes into powdered form. This is termed **tin disease** or **tin pest** or **tin plague**.

- (c) Tin is not attacked by organic acids. This property is utilised for tinning cooking vessels made of copper or brass.
- (d) Tin is largely used in forming a protective coating over iron. The process of depositing tin over the sheets of iron or steel is called **tin plating.**
- (e) Tin foil is used for wrapping cigarettes, confectionary and for making the tooth-paste tubes. Tin amalgam is used in making mirrors.
- (f) It is used for making useful alloys.
  (i) Solder Sn 67%, Pb 33% (ii) Bronze Cu 75–90%,
  Sn 10 25% (iii) Bell metal Cu 80%, Sn 20%.
- 29. SnCl<sub>4</sub> is hygroscopic and forms crystalline hydrates containing 3, 5, 6 and 8 molecules of water as water of crystallization. The pentahydrate, SnCl<sub>4</sub>·5H<sub>2</sub>O is known as butter of tin or oxymuriate of tin. It is used as a mordant, for

- fire proofing cotton and for increasing weight of silk.
- 30. SnCl<sub>2</sub>·2H<sub>2</sub>O is a crystalline solid. It is soluble in water. It acts as a reducing agent. It is used for making **purple of cassius** and as a mordant.
- **31.** Lead is mainly extracted from galena (PbS) ore. The ore is concentrated by froth floatation process. It is extracted either by air reduction process or carbon reduction process.
- 32. Pb is not affected by pure water. However, it dissolves slowly in water having dissolved oxygen. The dissolution of lead in water is known as **plumbosolvency**. Lead salts are poisonous in nature and lead pipes are often used in conveying water. In order to minimise dissolution, hard water is first conveyed which forms a protective layer on the inner walls.
- 33. Lead forms three oxides PbO, PbO<sub>2</sub> and Pb<sub>3</sub>O<sub>4</sub>. PbO<sub>2</sub> is a strong oxidising agent. Pb<sub>3</sub>O<sub>4</sub> is known as red lead (minium or sindhur). PbO<sub>2</sub> is used in storage batteries and in match industry. PbO exists in two forms (a) a yellow powder commonly known as massicot and (b) buff coloured form known as litharge. PbO is used for making glass, paints and varnishes.
- **34.** The solution of lead acetate is sweet in taste and is known as sugar of lead but it is poisonous in nature.
- 35. Basic lead carbonate (white lead), 2PbCO<sub>3</sub>·Pb(OH)<sub>2</sub> in linseed oil is used as white paint. It has large covering power but is poisonous and affected by H<sub>2</sub>S in air.
- 36. PbCrO<sub>4</sub>, chrome yellow is used as a yellow pigment and basic lead chromate PbCrO<sub>4</sub>·PbO known as chrome red, is also used as pigment.
- **37.** PbCl<sub>2</sub> is more ionic than PbCl<sub>4</sub>. It is more stable.
- **38.** Lead blocks are used to protect harmful emissions from radioactive minerals.
- **39.** Tetraethyl lead Pb(C<sub>2</sub>H<sub>5</sub>)<sub>4</sub> is used as an **antiknock** agent to improve the quality of gasoline.
- **40.** The hardness order of some abrasives is:
  Boron nitride > Diamond > Boron carbide > Silicon carbide

## Subjective Type Questions

#### 1. Answer the following:

- (a) Name three allotropic forms of carbon. Which one is a good conductor of electricity?
- (b) What is name of recently discovered allotrope of carbon, i.e., C<sub>60</sub>?
- (c) Which isotope of carbon is radioactive?
- (d) Which allotrope of carbon is used as a moderator in atomic reactors?
- (e) Name the purest form of carbon.

#### 2. Among group 14 elements name :

- (a) The element having highest tendency to form  $p\pi$ - $p\pi$  bonds.
- (b) The element which is most electropositive.
- (c) The element which is radioactive in nature.

- (d) The element which is most abundant in earth's crust.
- (e) The element which is used as a semiconductor.
- (f) The element which is commonly found in +2 oxidation state.

#### 3. Give reason for each of the following:

- (i) Why Ge, Sn and Pb show divalency?
- (ii) Out of methane and silane which is more stable and why?
- (iii) Aqueous solutions of carbonates of alkali metals are alkaline in nature?
- (iv) Carbon tetrachloride cannot be hydrolysed with water.
- (v) SnCl<sub>2</sub> is a solid while SnCl<sub>4</sub> is a liquid at room temperature.

#### 4. Answer the following:

PRACTICE PROBLEMS

- (a) Which is the basic building unit of all silicates?
- (b) Why are carbon compounds relatively inert?
- (c) What is dry ice? Why is it so called?

- (d) Why is diamond a bad conductor of electricity but a good conductor of heat?
- (e) Which halide of carbon is used as a refrigerant?

## 5. Indicate the principal ingredients of the following:

(a) Coal gas

[M.L.N.R. 1991]

(b) Producer gas

[M.L.N.R. 1991]

(c) Water gas

[M.L.N.R. 1991]

- (d) Natural gas
- (e) Soft glass
- (f) Hard glass

#### 6. What happens when the following are heated?

- (a) Red lead
- (b) Lead nitrate
- (c) Lead acetate
- (d) Hydrated stannous chloride
- (e) White lead

#### 7. What happens when?

- (i) Dilute nitric acid is slowly reacted with tin.
- (ii) Carbon dioxide is passed through a suspension of limestone in water. [I.I.T. 1991]
- (iii) Carbon and steam are heated.
- (iv) Red lead is treated with nitric acid. [M.L.N.R. 1992]
- (v) Iodine is added to stannous chloride.
- (vi) Carbon dioxide is passed through a concentrated aqueous solution of sodium chloride saturated with ammonia.
- (vii) Tin is treated with concentrated nitric acid.
- (viii) Lead is obtained from galena by air reduction.
- (ix) NaOH solution is added to SnCl2 solution.
- (x) Silica is heated with CaF<sub>2</sub> and conc. H<sub>2</sub>SO<sub>4</sub>.
- (xi) Stannous chloride reacts with ferric chloride.
- (xii) Stannous chloride reacts with mercuric chloride.
- (xiii) SnS reacts with yellow ammonium sulphide.
- (xiv) Lead is reacted with acetic acid in presence of oxygen.
- (xv) Nitrobenzene is treated with acidified stannous chloride.
- (xvi) Methyl chloride is passed over powdered silicon in the presence of copper catalyst at 275–375°C.
- (xvii) Potassium ferrocyanide is heated with conc. H<sub>2</sub>SO<sub>4</sub>.
- (xviii) Carbon monoxide is passed over nickel at 80°C.
- (xix) Silicon is fused with soda ash.
- (xx) Lead chloride is heated with conc. HCl.

#### 8. How will you prepare the following?

- (i) Tin metal from cassiterite.
- (ii) Litharge from red lead.
- (iii) Red lead from litharge.
- (iv) White lead from lead.
- (v) Stannous oxide from stannous chloride.
- (vi) Silanes from silicon.
- (vii) Crystalline silicon from silicon tetrachloride.
- (viii) Tetraethyl lead from sodium lead alloy.
- (ix) Chrome yellow from litharge.
- (x) Carbon monoxide from water gas.

#### 9. Answer the following:

- (i) Which elements have the electronic configuration  $ns^2 np^2$ ? Give their names.
- (ii) What is chemical formula of soft glass?
- (iii) What is gas carbon?

- (iv) What are carburetted water gas and semiwater gas?
- (v) What is a metal carbonyl?
- (vi) What is tin disease or tin plague?
- (vii) How does SiCl<sub>4</sub> differ from CCl<sub>4</sub>?
- (viii) What is plumbosolvency?
- 10. Write short notes on the following:
  - (i) Structure of diamond (ii) Structure of graphite
  - (iii) Alloys of tin
- (iv) Fuel gases
- (v) Silicones
- (vi) Various forms of coal
- (vii) Fire extinguisher
- (viii) Catenation
- 11. Explain the following with proper reasoning.
  - (i) Carbon dioxide does not support combustion but a burning magnesium ribbon continues to burn in it.

[Hint: Mg reduces CO<sub>2</sub> to carbon,

$$2Mg + CO_2 \longrightarrow 2MgO + C$$
  
and therefore continues to burn in  $CO_2$ .

(ii) Graphite is a conductor but diamond is not a conductor.

**[Hint :** Graphite has layer structure in which each carbon is  $sp^2$  hybridized.  $\pi$ -electrons are delocalised and conduct electricity. In diamond each carbon is  $sp^3$  hybridized and no mobile or delocalised electrons are available.]

(iii) Carbon tetrachloride is not affected but silicon tetrachloride is hydrolysed by water.

[**Hint**: In silicon *d*-orbitals are available, *i.e.*, it increases its coordination number to 6.

$$\begin{array}{c|c}
Cl & Si & Cl + 2H_2O \longrightarrow H \\
Cl & Si & Cl + 2H_2O \longrightarrow H
\end{array}$$

$$\begin{array}{c|c}
Cl & Cl & Cl \\
Cl & Cl & Cl
\end{array}$$

$$\begin{array}{c|c}
Cl & Cl & Cl \\
H & Cl & Cl
\end{array}$$

$$\begin{array}{c|c}
Cl & Cl & Cl
\end{array}$$

$$\begin{array}{c|c}
Cl & Cl
\end{array}$$

$$\begin{array}{c|c}
Cl & Cl
\end{array}$$

$$\begin{array}{c|c}
Cl & Cl
\end{array}$$

$$\begin{array}{c|c}
Cl & Cl
\end{array}$$

In carbon d-orbitals are not present.]

(iv) Dilute HCl is preferred to dilute H<sub>2</sub>SO<sub>4</sub> for the preparation of carbon dioxide from marble.

[**Hint**: In case of dilute H<sub>2</sub>SO<sub>4</sub>,CaSO<sub>4</sub> is formed. This is deposited on the surface of marble and acts as a protective layer. This layer stops the further reaction to liberate CO<sub>2</sub>.]

(v)  $\operatorname{Sn}^{2+}$  and  $\operatorname{Fe}^{3+}$  cannot coexist in the same solution.

[Hint: Redox reaction occurs.

$$2Fe^{3+} + Sn^{2+} \longrightarrow Sn^{4+} + 2Fe^{2+}$$
.

(vi) CCl<sub>4</sub> is used as fire extinguisher but not CS<sub>2</sub>.

[**Hint**: CCl<sub>4</sub> is heavy non-combustible liquid but CS<sub>2</sub> is highly combustible liquid.

$$2CS_2 + 5O_2 \longrightarrow 2CO + 4SO_2$$

(vii) Sn is used in making solder.

[Hint: It is easily fusible alloying metal.]

(viii) The lead of lead pencils is not lead but graphite.

[**Hint**: Graphite has the property of marking paper.]
(ix) PbO does not dissolve in H<sub>2</sub>SO<sub>4</sub> while SnO is soluble in H<sub>2</sub>SO<sub>4</sub>.

[Hint: PbSO<sub>4</sub> is insoluble while SnSO<sub>4</sub> is soluble in water.]

(x) Alkali cannot be stored in a Sn or Pb vessel.

[Hint: Sn and Pb dissolve in alkali.]

(xi) Alkanes are more stable than silanes.

[Hint: The C—C bond energy is higher than Si—Si bond energy.]

(xii) CCl<sub>4</sub> does not act as a Lewis acid while SiCl<sub>4</sub> and SnCl<sub>4</sub> act as Lewis acids.

[Hint: SiCl<sub>4</sub> and SnCl<sub>4</sub> act as Lewis acids as they can extend their coordination number beyond 4 due to the presence of *d*-orbitals.]

(xiii) Radioactive materials are shielded by lead blocks.

[Hint: The penetration of radioactive rays is minimum through lead.]

(xiv) SnCl<sub>2</sub> has high melting point (is solid) while SnCl<sub>4</sub> has low melting point (is a liquid).

[Hint: SnCl<sub>2</sub> has ionic nature while SnCl<sub>4</sub> is a covalent compound involving sp<sup>3</sup> hybridization.]

(xv) Lead pollution is caused by car exhaust.

[Hint: Lead tetraethyl is added to petrol as antiknock. It is evolved during ignition of petrol as lead tetrabromide which causes pollution.]

(xvi) Carbon atom is tetravalent inspite of the fact that there are only two unpaired electrons in it.

**[Hint :** One of the *p*-orbitals is empty. The *ns* electron pair is unpaired and the electron is shifted to *np* orbital, *i.e.*, in excited state, the electronic configuration is  $2s^1 2p_x^1 2p_y^1 2p_z^1$ . There is  $sp^3$  hybridization and four hybrid orbitals each having one electron come into existence, showing tetravalency.]

(xvii) PbCl<sub>4</sub> exists while PbBr<sub>4</sub> and PbI<sub>4</sub> do not exist.

[Hint: Pb<sup>4+</sup> is an oxidising agent and readily changes into Pb<sup>2+</sup>. The Br<sup>-</sup> and Γ ions are reducing agents. Thus, redox reaction occurs indicating that PbBr<sub>4</sub> and PbI<sub>4</sub> are unstable compounds.

$$Pb^{4+} + 4Br^{-} \longrightarrow PbBr_2 + Br_2$$

(xviii)  $CO_2$  is an acidic anhydride while  $PbO_2$  is basic anhydride.

[**Hint**: C is a non-metal. Its oxide, CO<sub>2</sub>, is thus acidic in nature while lead is a metal and its oxide is basic in nature.]

**12.** A substance (X) is dissolved in concentrated hydrochloric acid and on treating the solution with sodium hydroxide solution a white precipitate formed which dissolved in excess, giving a solution with strongly reducing properties.

On heating (X) with sulphur, a brown powder (Y) was formed which dissolved in yellow ammonium sulphide and on adding HCl, a yellow precipitate was formed.

When (X) was strongly heated in air, a white powder (Z) was obtained. When (Z) was fused with sodium hydroxide and extracted with hot water, white crystals were obtained. Identify (X), (Y) and (Z) and write the reactions.

13. An inorganic compound (A) is a strong reducing agent. Its hydrolysis in water gives a white turbidity (B). Aqueous solution of (A) gives a white precipitate (C) with NaOH solution which is soluble in excess of NaOH. (A) reduces auric chloride to produce purple of cassius. (A) also reduces iodine and gives chromyl chloride test. What are (A) to (C) and give the chemical reactions.

[Ans. (A) = 
$$SnCl_2$$
; (B) =  $Sn(OH)Cl$ ; (C) =  $Sn(OH)_2$   
 $SnCl_2 + H_2O \longrightarrow Sn(OH)Cl + HCl$   
(A) (B)  
 $SnCl_2 + NaOH \longrightarrow Sn(OH)_2 + 2NaCl$   
(C)  
 $Sn(OH)_2 + 2NaOH \longrightarrow Na_2SnO_2 + 2H_2O$   
 $3SnCl_2 + 2AuCl_3 \longrightarrow 3SnCl_4 + 2Au$   
 $SnCl_2 + 2HCl + I_2 \longrightarrow SnCl_4 + 2HI$ 

14. A colourless crystalline solid (BA) dissolves in water. When the solid is heated with concentrated  $H_2SO_4$ , a reddish brown gas (X) is liberated. A solution of the salt when treated with potassium chromate solution gives a yellow precipitate (Y) insoluble in acetic acid. The same solution gives a white precipitate which dissolves in excess of NaOH to form a compound (Z). Identify (X), (Y), (Z) and the salt (BA).

[Ans.  $(BA) = Pb(NO_3)_2$ ;  $(X) = NO_2$ ;  $(Y) = PbCrO_4$ ;  $(Z) = Na_2PbO_2$ ]

5. A white solid (A) is not completely soluble in dilute HCl or

15. A white solid (A) is not completely soluble in dilute HCl or dilute H<sub>2</sub>SO<sub>4</sub> but dissolves in dilute HNO<sub>3</sub> with effer-vescences. In the evolved gas, a burning magnesium ribbon-continues to burn. (A) when heated forms a yellow solid (B) which is an amphoteric oxide. (B) when heated in air forms a red coloured compound (C). (C) when dissolved in concentrated HNO<sub>3</sub> gives a brown residue (D). Identify (A) to (D).

[Ans. (A) = 
$$PbCO_3$$
; (B) =  $PbO$ ; (C) =  $Pb_3O_4$ ; (D) =  $PbO_2$ ]

- **16.** A white coloured inorganic salt (A) gives the following reactions:
  - (i) It is soluble in water and the solution has sweet taste. The solution turns black in presence of  $H_2S$ .
  - (ii) The solution gives a white precipitate with dilute HCl which is soluble in hot water.
  - (iii) The salt when heated gives acetone and a yellow coloured residue.

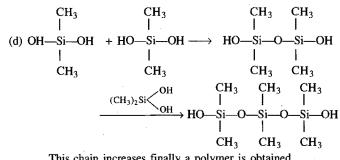

Identify the salt (A) and give chemical reactions.

[Ans. (A) is  $Pb(CH_3COO)_2$ 

$$\begin{array}{c} Pb(CH_3COO)_2 \,+\, H_2S \longrightarrow PbS \,+\, 2CH_3COOH \\ Black \\ Pb(CH_3COO)_2 \,+\, 2HCl \longrightarrow PbCl_2 \,+\, 2CH_3COOH \\ Soluble \ in \\ hot \ water \\ Pb(CH_3COO)_2 \longrightarrow PbO \,+\, CO_2 \,+\, CH_3COCH_3] \end{array}$$

- 17. Starting from SiCl<sub>4</sub> prepare the following in steps not exceeding the number given in parentheses (give reactions only):
  - (i) Silicon (I).
  - (ii) Linear silicon containing methyl groups only (4).
  - (iii) Na<sub>2</sub>SiO<sub>3</sub>(3). [I.I.T. 2001]

$$\begin{split} & [\textbf{Hint:} (i) \qquad SiCl_4 + 2Mg \longrightarrow Si + 2MgCl_2 \\ & (ii) \quad (a) \; SiCl_4 + 2Mg \longrightarrow Si + 2MgCl_2 \\ & \quad (b) \; Si + 2CH_3Cl \; \frac{Cu \; Catalyst}{280^\circ - 300^\circ C} \; (CH_3)_2 \; SiCl_2 \end{split}$$

This chain increases finally a polymer is obtained.

(iii) (a) 
$$SiCl_4 + 4H_2O \longrightarrow Si(OH)_4 + 4HCl$$

(b) 
$$Si(OH)_4 \xrightarrow{Heat} SiO_2 + 2H_2O$$

(c) 
$$SiO_2 + Na_2CO_3 \longrightarrow Na_2SiO_3 + CO_2$$

#### Matching Type Questions

#### Match the following:

- [A] (a) Red lead
- (i) Carbon
- (b) Litharge
- (ii) An ore of tin
- (c) Galena
- (iii) A white pigment

- (d) Cassiterite
- (e) Lignite
- (f) White lead
- (g) Chrome yellow
- (h) Chrome red
- [B] (a) Diamond
  - (b) Graphite
  - (c) Phosgene

  - (d) Producer gas
  - (e) Water glass
  - (f) Carbon monoxide
  - (g) Solid carbon dioxide
  - (h) Carbon dioxide gas
- [C] (a)  $SnCl_4.5H_2O$ 
  - (b) (CH<sub>3</sub>COO)<sub>2</sub>Pb
  - (c) PbO<sub>2</sub>
  - (d) SiC
  - (e) SnCl<sub>2</sub>
  - (f) Solder
  - (g) Silanes
  - (h) Na<sub>2</sub>O·CaO·6SiO<sub>2</sub>

- (iv) PbCrO<sub>4</sub>
- (v) Lead monoxide
- (vi) PbCrO<sub>4</sub>·PbO
- (vii) Minium
- (viii) An ore of lead
  - (i) A poisonous gas
  - (ii) Metal carbonyls
- (iii) A fuel
- (iv) Fire extinguisher
- (v) Refrigerant
- (vi) Lead pencils
- (vii) Sodium silicate
- (viii) Abrasive
  - (i) Carborundum
  - (ii) An alloy of tin and lead
- (iii) Soda glass
- (iv) Hydrides of silicon
- (v) Butter of tin
- (vi) An oxidising agent
- (vii) Sugar of lead
- (viii) A reducing agent

### tuswers

#### Answers: Subjective Type Questions

- 1. (a) Diamond, graphite and coal. Graphite is a good conductor of electricity.
  - (b) Fullerene or Bucky ball
  - (c) <sup>14</sup><sub>6</sub>C (used for carbon dating)
- (d) Diamond.
- 2. (a) Carbon
  - (b) Lead
  - (c) Ununquadium (114)
  - (d) Silicon
  - (e) Silicon and germanium
- (f) Lead
- 3. (i) Due to inert pair effect.
  - (ii) Methane. Silicon atom is bigger in size in comparison to hydrogen, thus, silane is unstable.
  - (iii) Carbonates of alkali metals are salts of strong bases and weak acid and hence undergo hydrolysis.
  - (iv) The maximum covalency of carbon is 4 due to absence of d-orbitals. It cannot expand its octet.
  - (v) SnCl<sub>2</sub> is an ionic compound while SnCl<sub>4</sub> is covalent in nature.
- (a) SiO<sub>4</sub><sup>4-</sup> is the basic building unit of all silicates.
  - (b) Carbon-carbon bond dissociation energy is quite high.
  - (c) Solid carbon dioxide, it does not wet the surface when it melts.
  - (d) Mobile electrons are not present in diamond. Conduction of electricity requires movement of electrons. The conduction of heat does not require movement of electrons.
  - (e) Freon, CF<sub>2</sub>Cl<sub>2</sub>.
- 5. (a) Coal gas—H<sub>2</sub>, CH<sub>4</sub>, CO, N<sub>2</sub>
  - (b) Producer gas—CO, N<sub>2</sub>
  - (c) Water gas-CO, H2
  - (d) Natural gas-CH<sub>4</sub>, C<sub>2</sub>H<sub>6</sub>, C<sub>3</sub>H<sub>8</sub>

- (e) Soft glass-Na2O, CaO, SiO2
- (f) Hard glass-K2O, CaO, SiO2
- 6. (a) On heating above 470°C, it decomposes into PbO and O2-

$$2Pb_3O_4 \longrightarrow 6PbO + O_2$$

(b) On heating, it breaks up into PbO, NO2 and O2.

$$2Pb(NO_3)_2 \longrightarrow 2PbO + 4NO_2 + O_2$$

(c) On heating, it decomposes giving acetone.

$$(CH_3COO)_2Pb \longrightarrow PbO + CO_2 + CH_3COCH_3$$

(d) Hydrolysis occurs with water of crystallisation.

$$SnCl_2 \cdot 2H_2O \longrightarrow Sn(OH)C1 + HC1 + H_2O$$

 $Sn + 10HNO_3(dil.) \longrightarrow 4Sn(NO_3)_2 + NH_4NO_3 + 3H_2O_3$ 

(e) On heating, it decomposes into red lead,

$$2PbCO_3 \cdot Pb(OH)_2 \longrightarrow Pb_3O_4 + CO + CO_2 + H_2$$

$$2HNO_3 + 8H \longrightarrow NH_4NO_3 + 3H_2O$$

(ii) Limestone dissolves in the form calcium bicarbonate.

$$CaCO_3 + H_2O + CO_2 \longrightarrow Ca(HCO_3)_2$$

(iii) Water gas is formed.

$$C + H_2O \longrightarrow \underbrace{CO + H_2}_{Water\ gas}$$

(iv) 
$$Pb_3O_4 \longrightarrow 2PbO + PbO_2$$

$$[PbO + 2HNO_3 \longrightarrow Pb(NO_3)_2 + H_2O] \times 2$$

$$Pb_3O_4 + 4HNO_3 \longrightarrow 2Pb(NO_3)_2 + PbO_2 + 2H_2O_3$$

(v) It decolourises iodine.

$$2SnCl_2 + 2I_2 \longrightarrow 2SnCl_2I_2 \longrightarrow SnCl_4 + SnI_4$$

(vi) 
$$NH_4OH + CO_2 \longrightarrow NH_4HCO_3$$

$$NaCl + NH_4HCO_3 \longrightarrow NaHCO_3 + NH_4Cl$$

$$NaCl + NH_4OH + CO_2 \longrightarrow NaHCO_3 + NH_4Cl$$

$$\begin{array}{cccc} (vii) & & [2HNO_3 & \longrightarrow & H_2O + 2NO_2 + O] \times 2 \\ & & \underline{Sn + 2O + H_2O \longrightarrow & H_2SnO_3} \\ & & & \underline{Sn + 4HNO_3 \longrightarrow & H_2SnO_3 + 4NO_2 + H_2O} \\ & & & \underline{Metastannic \ acid} \end{array}$$

(viii) 
$$2PbS + O_2 \longrightarrow 2PbO + SO_2$$
  
 $PbS + 2O_2 \longrightarrow PbSO_4$ 

Roasted in a limited supply of oxygen. Air supply is cut-off and fresh galena is added and the temperature is raised. Galena reduces both PbO and PbSO<sub>4</sub> to metallic lead.

$$2PbO + PbS \longrightarrow 3Pb + SO_2$$

$$PbSO_4 + PbS \longrightarrow 2Pb + 2SO_2$$

(ix) 
$$SnCl_2 + 2NaOH \longrightarrow Sn(OH)_2 + 2NaCl$$
  
 $Sn(OH)_2 + 2NaOH \longrightarrow Na_2SnO_2 + 2H_2O$ 

$$\frac{2}{\text{SnCl}_2 + 4\text{NaOH} \longrightarrow \text{Na}_2\text{SnO}_2 + 2\text{NaCl} + 2\text{H}_2\text{O}}$$

(x) 
$$[CaF_2 + H_2SO_4 \longrightarrow CaSO_4 + 2HF] \times 2$$

$$SiO_2 + 4HF \longrightarrow SiF_4 + 2H_2O$$

$$2CaF_2 + SiO_2 + 2H_2SO_4 \longrightarrow 2CaSO_4 + SiF_4 + 2H_2O$$

$$SnCl_2 + 2FeCl_3 \longrightarrow SnCl_4 + 2FeCl_2$$

(xii) 
$$HgCl_2 + SnCl_2 \longrightarrow Hg + SnCl_4$$

(xiii) 
$$SnS + S \longrightarrow SnS_2$$

$$SnS_2 + (NH_4)_2S \longrightarrow (NH_4)_2SnS_3$$

(xiv) Pb + 2CH<sub>3</sub>COOH + 
$$\frac{1}{2}$$
 O<sub>2</sub>  $\longrightarrow$  (CH<sub>3</sub>COO)<sub>2</sub>Pb + H<sub>2</sub>O

$$(xv) C_6H_5NO_2 + 6HCl + 3SnCl_2 \longrightarrow C_6H_5NH_2 + 3SnCl_4 + 2H_2O$$

(xvi) 
$$2CH_3Cl + Si \xrightarrow{Cu} (CH_3)_2SiCl_2$$

$$(xvii)K_4Fe(CN)_6 + 3H_2SO_4 \longrightarrow 2K_2SO_4 + FeSO_4 + 6HCN$$

$$[HCN + 2H_2O \longrightarrow HCOOH + NH_3] \times 6$$

$$[2NH_3 + H_2SO_4 \longrightarrow (NH_4)_2SO_4] \times 3$$

$$[HCOOH \longrightarrow CO + H_2O] \times 6$$

$$K_4Fe(CN)_6 + 6H_2SO_4 + 6H_2O \longrightarrow 2K_2SO_4 + FeSO_4 +$$

$$3(NH_4)_2SO_4 + 6CO$$

(xviii) Ni + 4CO 
$$\longrightarrow$$
 Ni(CO)<sub>4</sub>

Nickel carbonyl

(xix) 
$$Si + Na_2CO_3 \longrightarrow Na_2SiO_3 + C$$

$$\begin{array}{ccc} \text{(xx)} & & \text{PbCl}_2 + 2\text{HCl} & \longrightarrow & \text{H}_2\text{PbCl}_4 \\ & & \text{Chloroplumbous acid} \\ & & \text{(Soluble)} \end{array}$$

3. (i) The ore is first roasted to remove sulphur, arsenic as SO<sub>2</sub> and As<sub>2</sub>O<sub>3</sub> respectively. The roasted mass is mixed with about one fifth its mass of powdered anthracite and a little lime. The mixture is heated in reverberatory furnace when tin metal is formed.

$$SnO_2 + 2C \longrightarrow Sn + 2CO$$

(ii) On heating above 470°C, red lead decomposes into litharge.  $2Pb_3O_4 \longrightarrow 6PbO + O_2$ 

(iii) On heating litharge in air about 450°C.

$$6PbO + O_2 \longrightarrow 2Pb_3O_4$$

- (iv) Lead is converted into white lead by Dutch process or electrolytic process. See text on page 436.
- (v) NaOH is added to stannous chloride. The stannous hydroxide precipitated is heated in atmosphere of CO<sub>2</sub>.

$$SnCl_2 + 2NaOH \longrightarrow Sn(OH)_2 + 2NaCl$$
  
 $Sn(OH)_2 \xrightarrow{Heat, CO_2} SnO + H_2O$ 

(vi) Silicon is fused with magnesium. Magnesium silicide is now treated with dilute HCl when a mixture of silicon hydrides is obtained.

$$2Mg + Si \longrightarrow Mg_2Si \xrightarrow{Dil. HCl} A$$
 mixture of silicon hydrides (Silanes)

(vii) By passing a current of silicon tetrachloride over molten aluminium.

$$3SiCl_4 + 4Al \longrightarrow 3Si + 4AlCl_3$$

(viii) 
$$4C_2H_5C_1 + 4Pb$$
—Na  $\longrightarrow (C_2H_5)_4Pb + 4NaC_1 + 3Pb$ 

(ix) PbO + 2CH<sub>3</sub>COOH 
$$\longrightarrow$$
 (CH<sub>3</sub>COO)<sub>2</sub>Pb + H<sub>2</sub>O  
(CH<sub>3</sub>COO)<sub>2</sub>Pb + K<sub>2</sub>CrO<sub>4</sub>  $\longrightarrow$  PbCrO<sub>4</sub> + 2CH<sub>3</sub>COOK  
Chrome yellow

x)  $\underbrace{\text{CO} + \text{H}_2}_{\text{Water gas}} \xrightarrow{200 \text{ atm.}}_{\text{Amm.Cu}_2\text{Cl}_2} \text{CO is absorbed.}$ 

It is released when pressure is removed.

- (i) Elements of IVA or 14th group : Carbon, Silicon, Germanium, Tin and Lead.
  - (ii) Na<sub>2</sub>SiO<sub>3</sub>·CaSiO<sub>3</sub>·4SiO<sub>2</sub>
  - (iii) The amorphous form of carbon obtained by scrapping the walls of a retort which has been used in destructive distillation of coal.
  - (iv) The water gas mixed with volatile hydrocarbons is known as carburetted water gas. Semiwater gas is a mixture of water gas and producer gas. It is obtained by passing a mixture of steam and air over incandescent coke.
  - (v) A coordination compound of metal with carbon monoxide molecules as ligands is known as metal carbonyl.
  - (vi) The crumbling of white tin into grey powder from a very low temperature is called tin disease or tin plague.
  - (vii) CCl<sub>4</sub> does not undergo hydrolysis while SiCl<sub>4</sub> undergoes hydrolysis.
  - (viii) The dissolution of lead in water in presence of dissolved oxygen is known as plumbosolvency.

12. 
$$X = Sn$$
;  $Y = SnS$ ;  $Z = SnO_2$ 

$$\operatorname{Sn} + 2\operatorname{HCl} \longrightarrow \operatorname{SnCl}_2 + \operatorname{H}_2$$
(X)

$$SnCl_2 + 2NaOH \longrightarrow Sn(OH)_2 + 2NaCl$$
  
 $Sn(OH)_2 + 2NaOH \longrightarrow Na_2SnO_2 + 2H_2O$ 

$$Sn + S \longrightarrow SnS$$
(Y) Brown

$$SnS + (NH4)2SnS2 \longrightarrow (NH4)2SnS3$$

$$(NH_4)_2SnS_3 + 2HCl \longrightarrow SnS_2 + H_2S + 2NH_4Cl$$

$$Sn + O_2 \longrightarrow SnO_2$$

$$SnO_2 + 2NaOH \longrightarrow Na_2SnO_3 + H_2O$$

#### Answers: Matching Type Questions

## ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. Graphite is not:
  - (a) a good conductor of heat
  - (b) an amorphous allotrope of carbon
  - (c) softer than diamond:
  - (d) used for making lubricants

Ans. (b)

[Hint: Graphite is crystalline allotrope of carbon.]

- **2.** Carbon atoms in diamond are bonded with each other in a configuration :
  - (a) linear

(b) planar

(c) tetrahedral

(d) octahedral

Ans. (c)

- 3. When heated with concentrated H<sub>2</sub>SO<sub>4</sub>, K<sub>4</sub>Fe(CN)<sub>6</sub> gives :
  - (a) CO

(b) CO<sub>2</sub>

(c) (CN)<sub>2</sub> and CO

(d)  $(CN)_2$  and  $CO_2$ 

Ans. (a)

[Hint:  $K_4Fe(CN)_6 + 6H_2SO_4 + 6H_2O \longrightarrow 2K_2SO_4 + FeSO_4 + 3(NH_4)_2SO_4 + 6CO$ ]

- 4. Carbon monoxide is absorbed by:
  - (a) plants
  - (b) alcohol
  - (c) Ni(CO)<sub>4</sub>
  - (d) ammonical solution of cuprous chloride

Ans. (d)

[Hint: All the four valencies of carbon are not satisfied. It behaves as an unsaturated compound and forms addition products.

$$\begin{array}{ccc} CuCl & + CO & \xrightarrow{High} & CuCl \cdot CO] \\ Ammonical & solution & & \end{array}$$

- 5. Which of the following is correct?
  - (a) Silicones are organosilico polymers containing Si—O—Si linkage.
  - (b)  $R_3$ SiCl on hydrolysis gives  $R_3$ Si—O—Si $R_3$
  - (c) Both
  - (d) None

Ans. (c)

- 6. The general formula of cyclic or ring silicates is:
  - (a)  $(Si_2O_5)_n^{2n}$

(b)  $(SiO_3)_n^{2n}$ 

(c)  $(SiO_3^{2-})_n$ 

(d) both (b) and (c)

Ans. (d)

- 7. Which one of the following statements is wrong?
  - (a) Ionic carbides are formed by highly electropositive metals.
  - (b) Carborundum and boron carbide are true covalent carbide.
  - (c) Carborundum and boron carbide are used as abrasive.
  - (d)  $Mg_2C_3$  like  $CaC_2$  on hydrolysis evolves  $C_2H_2$ .

Ans. (d)

[Hint:  $Mg_2C_3$  on hydrolysis evolves propyne.  $Mg_2C_3 + 4H_2O$  $\longrightarrow 2Mg(OH)_2 + CH_3-C = CH \text{ (propyne)}]$ 

- **8.** In  $(SiO_4)^{4-}$  (tetrahedral structure), three oxygen atoms are shared in which of the following? [I.I.T. 2005]
  - (a) Sheet silicates

(b) Three dimensional silicates

(c) Linear silicate

(d) Pyrosilicate

Ans. (a)

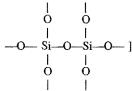

[Hint: See page No. 427]

9. In silicon dioxide:

[A.I.E.E.E. 2005]

- (a) each silicon atom is surrounded by four oxygen atoms and each oxygen atom is bonded to two silicon atoms
- (b) each silicon atom is surrounded by two oxygen atoms and each oxygen atom is bonded to two silicon atoms
- (c) silicon atom is bonded to two oxygen atoms
- (d) there are double bonds between silicon and oxygen atoms. **Ans.** (a)

[Hint: Each silicon atom is surrounded tetrahedrally by four oxygen atoms.

10. Silica reacts with magnesium to form a magnesium compound (X). (X) reacts with dilute HCl and forms (Y). (Y) is:

[E.A.M.C.E.T. 2004]

(a) MgO

- (b) MgCl<sub>2</sub>
- (c) MgSiO
- (d) SiCl<sub>4</sub>

Ans. (b)

[Hint: 
$$SiO_2 + 2Mg \longrightarrow 2MgO + Si$$
;  $MgO + 2HCl \longrightarrow MgCl_2$ 

$$(X) \qquad (Y)$$

$$+ H_2O]$$

- 11. Silica is reacted with sodium carbonate. What is the gas liberated? [E.A.M.C.E.T. 2005]
  - (a) CO

(b) O<sub>2</sub>

(c) CO<sub>2</sub>

(d) O<sub>3</sub>

Ans. (c)

[Hint:  $SiO_2 + Na_2CO_3 \longrightarrow Na_2SiO_3 + CO_2$ ]

12. Pb and Sn are extracted from their chief ores by:

[I.I.T. 2004]

- (a) carbon reduction and self reduction
- (b) self reduction and carbon reduction
- (c) electrolysis and self reduction
- (d) self reduction and electrolysis

Ans. (b)

[Hint: PbS + 2PbO  $\longrightarrow$  3Pb + SO<sub>2</sub> (self reduction); SnO<sub>2</sub> + C  $\longrightarrow$  Sn + CO<sub>2</sub> (carbon reduction)]

13. The soldiers of Napoleon army while at Alps during freezing winter suffered a serious problem as regards to tin buttons of their uniforms. White metallic buttons of tin got converted to grey powder. This transformation is related to:

[A.I.E.E.E. 2004]

- (a) an interaction with nitrogen of the air with very low temperature
  (b) an interaction with water vapour present in humid air
  (c) a change in the partial pressure of oxygen present in the air
  (d) a change in the crystalline structure of tin
  Ans. (d)
  [Hint: White tin converts itself into grey tin at 18°C.]
  14. Ge (II) compounds are powerful reducing agents whereas Pb (IV) compounds are strong oxidants. It can be due to:
  (a) Pb is more electronegative than Ge
  (b) ionisation potential of lead is less than that of Ge
- (c) ionic radii of Pb<sup>2+</sup> and Pb<sup>4+</sup> are larger than those of Ge<sup>2+</sup> and Ge<sup>4+</sup>
- (d) more pronounced inert pair effect in lead than in Ge.

Ans. (d)

**15.** Buckminsterfullerene is :

(a) graphite

(b) diamond

(c) C-60

(d) bone charcoal

Ans. (c)

[Hint: Fullerene, a carbon allotrope, consists of spherical C-60 molecules with the extra ordinary shape of a soccer ball. It has 12 pentagonal and 20 hexagonal faces with each atom  $sp^2$  hybridized and bonded to three other atoms.]

#### **OBJECTIVE QUESTIONS**

Set I:	This set	cont	ains	ques	stions	with	singl	le corr	ect answer.

1.	In the ground state the carbon atom has unpaired	10.	Which of the following is the chemically inactive allotre	opic
	electron/electrons:		form of carbon?	
	(a) 2 $\square$ (b) 3 $\square$	-	(a) diamond	$\Box$
	(c) 4 $\square$ (d) no $\square$		(c) charcoal	
2.	What is the general electronic configuration of group 14 or	11.	The use of diamond as a gem depends on its:	
	IVA elements:		(a) hardness $\square$ (b) high refractive index	
	(a) $ns^2 np^4$		(c) purest form of carbon □ (d) chemical inertness	
		12.	CO forms a volatile compound with:	
3.	The element which forms only one hydride is:		(a) nickel	
	(a) C $\square$ (b) Si $\square$		(c) sodium	
	(c) Pb $\Box$ (d) none of these $\Box$	13.	A colourless gas which burns with blue flame and red	uces
4.	Carbon shows tetravalency due to:		CuO to Cu is:	
	(a) $s^2p^2$ hybridization $\square$ (b) $d^3p$ hybridization $\square$		(a) $N_2$	
	(c) $dsp^2$ hybridization $\Box$ (d) $sp^3$ hybridization $\Box$		(c) $CO_2$	
5.	In group IVA or 14 of the extended form of the periodic table	14.	Fire extinguishers contain a bottle of H <sub>2</sub> SO <sub>4</sub> and:	
	with increase in atomic number, the metallic character:		(a) CaCO <sub>3</sub>	
	(a) increases		(c) NaHCO <sub>3</sub>	
-	(b) decreases	15	$H_2SO_4$ is not used for the preparation of $CO_2$ from ma	
	(c) remains the same	13.	chips because:	1010
_	(d) first increases then decreases	}	(a) it does not react	
6.	The species present in solution when CO <sub>2</sub> is dissolved in		(b) huge amount of heat is evolved	
	water:		(c) the reaction is vigorous	
	(a) $H_2CO_3, CO_3^{2-}$	ļ	(d) calcium sulphate is sparingly soluble and get depos	
	(b) HCO <sub>3</sub> , CO <sub>3</sub> <sup>2</sup>		on marble chips and stops the reaction	,nca
	(c) CO <sub>2</sub> , H <sub>2</sub> CO <sub>3</sub>	16	Producer gas is the mixture of:	. –
	\-\(\frac{1}{2}\) - \(\frac{1}{2}\) - \(\frac{1}{2}\) - \(\frac{1}{2}\) - \(\frac{1}{2}\) - \(\frac{1}{2}\) - \(\frac{1}{2}\)	10.	(a) CO and $N_2$	
	[Hint: $CO_2 + H_2O \Longrightarrow H_2CO_3 \Longrightarrow H^+ + HCO_3^- \Longrightarrow 2H^+ + CO_3^{2-}$ ]		(c) $N_2$ and $NH_3$ $\square$ (d) $CO$ , $H_2$ and $N_2$	
7	Diamond and graphite are:	17	A dry ice piece is composed of:	
/.	(a) isomers	17.		
	(c) isotopes		(a) solid He $\Box$ (b) solid $CO_2$ (c) solid $SO_2$ $\Box$ (d) solid $C_6H_6$	
R	Carbon has valency four in CH <sub>4</sub> . Its valency in acetylene is:	18	In laboratory burners, we use:	
0.	(a) 1	10.	(a) producer gas $\Box$ (b) coal gas	
	(c) 3 $\square$ (d) 4 $\square$			
9	Which of the following is a good conductor of electricity?	10	(c) oil gas	
٦.	(a) diamond $\Box$ (b) graphite $\Box$	19	Maximum ability of catenation is shown by:	
	(c) coal $\Box$ (d) none of these $\Box$		(a) carbon ☐ (b) nitrogen ☐ (c) oxygen ☐ (d) sulphur	
	(a) none of those	1	(c) oxygen	

20.	Graphite is a good conductor of electricity because it	32.	The structure and hybridization of Si(CH <sub>3</sub> ) <sub>4</sub> is:	
	contains:		\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\	]
	(a) bonded electrons $\Box$ (b) mobile electrons $\Box$		(c) octahedral, $sp^3d^2$ $\square$ (d) tetrahedral, $sp^3$ $\square$	
	(c) strong C—C bonds □ (d) strong C=C bonds □	33.	Among the following substituted silanes, the one which wi	11
21.	Which form of the carbon has a two dimensional sheet like	:	give rise to cross linked silicone polymer on hydrolysis is	:
	structure?		(a) $RSiCl_3$ $\square$ (b) $R_4Si$	]
	(a) Diamond		(c) $R_2 \text{SiCl}_2$	]
	(c) Graphite	34.	Structural units of ice and dry ice are respectively:	
22.	If CO <sub>2</sub> is passed in excess into lime water, the milkiness first		(a) $H_2O$ , $CO$ $\Box$ (b) $CO_2$ , $H_2O$	]
	formed disappears due to:		(c) $H_2O, CO_2$ $\square$ (d) $CO, CO_2$	
	(a) reversal of the original reaction	35.	Which of the following is a semiconductor?	
	(b) formation of volatile calcium derivative			
	(c) formation of water soluble calcium bicarbonate	- 1	(c) Ge	J
	(d) the solution getting heated by exothermic reaction	1 00	Carbon atoms in diamond are bonded with each other in	a
23.	When steam is passed through red hot coke:		configuration:	
۵.	(a) CO <sub>2</sub> and H <sub>2</sub> are obtained		(a) linear	
	(b) CO and N <sub>2</sub> are formed		\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \	
	* *	1 27		
		<b>.</b>		3-
~4	(d) petrol gas is obtained	'		_
24.	Glass could be considered as:		(c) it is neither combustible nor a supporter of combustion	
	(a) amorphous solid	1		ה ר
	(c) crystalline solid $\Box$ (d) super cooled liquid $\Box$		(d) it is a colourless gas	_
25.	An important ore of lead is:	38	— · · · · · · · · · · · · · · · · · · ·	_
	(a) magnesite	50	expansion is:	
	(c) bauxite			
26.	Glass is soluble in:			_
	(a) HF $\square$ (b) H <sub>2</sub> SO <sub>4</sub> $\square$	30	When the destructive distillation of coal is done, the	
	(c) HClO <sub>4</sub>		non-volatile residue left in the retort is:	ıc
27.	An alloy which does not contain copper is:			_
	(a) bell metal			_
	(c) brass	40		_
28.	Coal gas is a mixture of:	1.40	gives more of:	g
	(a) CO and H <sub>2</sub>			7
	(b) H <sub>2</sub> , saturated and unsaturated hydrocarbons, CO, CO <sub>2</sub>	.	* *	
	$N_2$ and $O_2$	. 1	For complete combustion of a fuel we shall need:	
	(c) saturated and unsaturated hydrocarbons	41	<del>-</del>	_
	(d) CO, CO <sub>2</sub> and CH <sub>4</sub>		( )	
29.	[SiO <sub>4</sub> ] <sup>4-</sup> has tetrahedral structure, the silicate formed by using	1		<u></u>
	three oxygen has a:	'		
	(a) linear polymeric structure	I <sub>42</sub>		_
	(b) three dimensional structure	1		7
	(c) pyrosilicate structure	1		_
	(d) two dimensional sheet structure		* •	
30.	Coal gas:	<b>'</b>	* * *	
50.		1 40		
	(a) burns with a smoky flame	. 1	Colour is imparted to glass by mixing:	_
	(b) burns with non-smoky flame	_		_
	(c) is not used for lighting purposes	į.	* *	
	(d) is not a good fuel	I   44		
31.	Mark the correct statement:	.	J.E.E. (Orissa) 2010	_
	(a) Water gas is used in the manufacture of methyl alcoho	. !	`/ +	_
	(b) Water gas has the highest calorific value	1	The poisonous gas present in the exhaust fumes of car is	_
	(c) Water gas burns with luminous flame			_
	(d) The production of water gas is exothermic process.	1 (	(c) carbon monoxide	

46.	Phosgene is the common name given to:	_		(d) it has strong catenation property	
	(a) carbonyl chloride	빌ㅣ	61.	The heat of combustion of carbon is 94 kcal. The calori	tic
	(c) phosphorus oxychloride			value of carbon is about:	_
	(d) phosphorus trichloride			_ (5) 1515 1515	
47.	Red lead is:	_	<i>(</i> 2	_ (4)	
	(a) PbO $\square$ (b) PbO <sub>2</sub>		62.	Which compound is called sugar of lead?	_
	(c) $Pb_3O_4$			(a) $PbCl_2$	
48.	Which of the following halides is least stable and h	nas	· .	(5) 10004	
	doubtful existence?	_	63.	The number and type of bonds between two carbon ator	ms
	(a) $CI_4$			in CaC <sub>2</sub> are:	_
	(c) $GeI_4$			(a) one sigma and one pi bond	닏
49.	Which one of the oxides is neutral?	_ 1		(b) one sigma and two pi bonds	
	(a) CO $\square$ (b) SnO <sub>2</sub>			(c) one sigma and one and a half pi bond	
	(c) $ZnO$ $\Box$ (d) $SiO_2$			(d) one sigma bond	
50.	An example of major air pollutant is:	_	64.	When a mixture of air and steam is passed over red hot col	ke,
	(a) $O_2$			the outgoing gas contains:	
	(c) CO			()	
51.	*			(c) coal gas	
	(a) it combines with water to give carbonic acid		65.	Tin reacts with conc. HNO <sub>3</sub> and gives:	_
	(b) it combines with haemoglobin of the blood			(a) stannic nitrate	
	(c) it is a powerful oxidising agent			(c) metastannic acid	
	(d) it is used to prepare aerated water		66.	Which substance is used as lubricant?	_
52.	Which of the following compounds is used as a reduc-	ing		(a) $SnCl_2$	
	agent?		/	(c) graphite	
	(a) $SnO_2$ $\square$ (b) $SnS_2$		67.	The colour imparted by Co(II) compounds to glass is:	
	(c) $SnCl_4$			[A.I.I.M.S. 20	06J
53.	Which of the following statements is not correct?			(a) deep blue	님
	(a) Lead salts are slow poisons		<b>CO</b>	(c) yellow	
	(b) Lead metal is used in accumulators		68.	The principal constituent of pyrex glass is:	_
	(c) Plumbosolvency increases by the presence of car			(a) Zn	
	nates, sulphates, phosphates, etc.		<b>40</b>	(c) Pb	
~.	(d) Lead is a soft metal		69.	The difference in properties of $CH_4$ and $SiH_4$ is due to:	
54.	Chrome yellow is chemically called:	_		(a) large difference in the electronegativity of carbon a	ana
	(a) lead chromate			silicon	
	(c) lead iodide		l I	(b) large difference in size of carbon and silicon atoms	
55.				(c) the inability of carbon to expand its octet	
	(a) Pb(OH) <sub>2</sub> ·PbCO <sub>3</sub>		70	(d) the inability of silicon to form double bonds	
56	(c) Pb(OH) <sub>2</sub> ·Pb(CH <sub>3</sub> COO) <sub>2</sub> (d) PbCO <sub>3</sub> ·PbO		70.		IIO-
56.	<b>-</b>			lysed because:	and
	(a) $CaC_2$ $\square$ (b) $Al_4C_3$ (c) $WC$ $\square$ (d) $SiC$			(a) carbon cannot expand its octet but silicon can expa	П
57		ш		its octet  (b) ionication potential of carbon is higher than silicon.	
57.				<ul><li>(b) ionisation potential of carbon is higher than silicon</li><li>(c) carbon forms double and triple bonds</li></ul>	
				(d) electronegativity of carbon is higher than that of silic	COD
58.	(c) $C_3O_2$			(d) electronegativity of carbon is nigher than that of sine	
50.	sodium hydroxide solution:	O)	71	Which of the following oxides has three dimension	mal
	(a) $Fe^{3+}$		/1.	structure?	niai
	(a) Fe $\square  (b) \text{ C1}$ (c) $\text{Sn}^{2+} \qquad \square  (d) \text{ Cu}^{2+}$			() 65	
50		LI			
59.	(a) Na <sub>2</sub> O		72.	(c) SiO <sub>2</sub>	
	(a) $Na_2O$ $\square$ (b) $NO$ (c) $CaO$ $\square$ (d) $SnO$		12.	This shows that carbon has:	<b>℃</b> 2.
60.				(a) two allotropic forms	
ω.	(a) carbon is tetra-valent	<del>:.</del> □		(b) two oxidation states	
	(b) it has non-metallic character			(c) two oxidation states	
	(c) it shows allotropy			(d) four electrons in valency shells	
	THE AS DALOTTO MILITARY		1	in ton continue in the city diffin	-

73.	In silicon dioxide:	86.	Solder is an alloy of: [A.F.M.C. 20	005]
	(a) there are double bonds between silicon and oxygen		(a) 70 % Pb, 30 % Sn	
	atoms		(c) 80 % Pb, 20 % Sn	
	(b) each silicon atom is surounded by four oxygen atoms	87.	Solid carbon dioxide is used as:	
	and each oxygen atom is bonded to two silicon atoms		(a) poison	
			(c) refrigerant	
	(c) silicon is bonded to two silicon atoms $\Box$	88.	When PbO <sub>2</sub> reacts with conc. HNO <sub>3</sub> , the gas evolved is	s:
	(d) each silicon atom is surrounded by two oxygen atoms		[A.I.E.E.E. 20	105]
	and each oxygen atom is bonded to two silicon atoms	<u>.</u>	(a) $NO_2$	
			(c) $N_2$	
74.	In the manufacture of glass the addition of MnO <sub>2</sub> gives:	89.	When steam reacts with red hot coke to form CO2 a	and
	(a) yellow colour $\Box$ (b) red colour $\Box$		hydrogen:	
	(c) violet colour $\Box$ (d) pink colour $\Box$		(a) water acts as oxidising agent	
<i>7</i> 5.	Which is not used as pigment in paints?		(b) water acts as reducing agent	
	(a) $PbCrO_4$ $\square$ (b) $PbO_2$ $\square$		(c) carbon acts as oxidising agent	
	(c) White lead $\Box$ (d) Pb <sub>3</sub> O <sub>4</sub> $\Box$		(d) there is no oxidation or reduction .	
76.	Lead dissolves most readily in:	90.	, .	
	(a) acetic acid $\Box$ (b) sulphuric acid $\Box$		(a) CO + steam $\Box$ (b) CO + N <sub>2</sub>	
	(c) nitric acid $\Box$ (d) hydrochloric acid $\Box$		(c) $CO + H_2$	
77.	Which of the following metals is an important ingredient of	91.	e; e	
	transistors?		(a) -Sn—Sn	
	(a) Osmium		(c) Si—Si	
	(c) Gold $\Box$ (d) Sodium $\Box$	92.	Graphite is soft and lubricant, extremely difficult to melt.	The
78.	The gas which is present both in producer gas and in water		reason for this anomalous behaviour is that graphite:	
	gas is:		[A.I.E.E.E. 20	
	(a) $N_2$ $\square$ (b) $H_2$ $\square$		(a) has carbon atoms arranged in large plates of rings	
	(c) CO $\square$ (d) CO <sub>2</sub> $\square$		strongly bound carbon atoms with weak interp	late
79.	Which glass has the highest percentage of lead?		bonds	
	(a) Soda glass $\Box$ (b) Flint glass $\Box$		(b) is a non-crystalline substance	
	(c) Jena glass $\Box$ (d) Pyrex glass $\Box$		(c) is an allotrope form of carbon	
80.	Which does not exist?		(d) has molecules of variable molecular masses polymers	
	(a) $[CCl_6]^2$	93.	Which of the following is correct composition of water g	
	(c) $[GeF_6]^{2-}$ $\Box$ (d) $[SnCl_6]^{2-}$ $\Box$	93.	(a) $CO + Cl_2$	
81.	The material used in solar cells contains:		(a) $CO + CI_2$ $\Box$ (b) $CO + II_2$ (c) $CO + H_2$ $\Box$ (d) $CO + H_2 + N_2$	
•	(a) Si $\Box$ (b) Sn $\Box$	94	What is the formula of carbon suboxide?	
	(c) Ti $\Box$ (d) Cs $\Box$	"	(a) CO $\Box$ (b) CO <sub>2</sub>	
82.	'Softening of lead' means:	ļ	(c) $C_2O_4$ $\square$ (d) $C_3O_2$	
*	(a) conversion of lead to PbO	95.	Which of the following halide of carbon is used	
	(b) conversion of lead to $Pb_3O_4$		refrigerant?	
	(c) removal of impurities (metallic) from lead		(a) $CCl_4$ $\Box$ (b) $CF_4$	
	(d) washing lead with HNO <sub>3</sub> followed by a dil. alkali	,	(c) $CH_2Cl_2$ $\square$ (d) $CH_2F_2$	
	solution	96.	The carbide which gives propyne on hydrolysis:	
83.	'Lead pencil' contains:		(a) $Al_4C_3$ $\Box$ (b) $CaC_2$	
	(a) graphite		(c) $Fe_3C$ $\Box$ (d) $Mg_2C_3$	
	(c) charcoal . □ (d) lead sulphide □	97.	Which among the following carbides is methanide?	
84.	Electrolytic bath in electrolytic refining of lead contains:		(a) $Al_4C_3$ $\Box$ (b) $CaC_2$	
	(a) $H_2SiF_6$ only		(c) $Be_2C$ $\square$ (d) $SiC$	
	(b) PbSiF <sub>6</sub> only $\Box$	98.	Percentage of lead in lead pencil is:	
	(c) H <sub>2</sub> SiF <sub>6</sub> in presence of gelatin		(a) zero	
	(d) $H_2SiF_6$ and $PbSiF_6$ in presence of gelatin		(c) 80	
85.	Which of the following oxides is amphoteric in character?	99.	CCl <sub>4</sub> is used as fire extinguisher because:	_
	[A.I.E.E.E. 2005]		(a) its m.pt. is high $\Box$ (b) it forms covalent bon	
	(a) CaO $\Box$ (b) CO <sub>2</sub> $\Box$		(c) its b.pt. is low	
	(c) $SiO_2$ $\Box$ (d) $SnO_2$ $\Box$	1	(d) it gives incombustible vapours	П

100.	The correct order of increasing C—O bond length of CO, $CO_3^{2-}$ , $CO_2$ is: [C.B.S.E. 2007]	112.	Which is likely to show inert pair effect?
	(a) $CO_3^{2-} < CO_2 < CO$		[D.C.E. (Engg.) 2007] (a) K
			(a) K $\square$ (b) Mg $\square$ (c) Al $\square$ (d) Pb $\square$
101	(c) $CO < CO_3^2 < CO_2$	113.	The stability of dihalides of Si, Ge, Sn and Pb increases
101.	PbF <sub>4</sub> , PbCl <sub>4</sub> exists but PbBr <sub>4</sub> and PbI <sub>4</sub> do not exist	115.	
	because of: [C.E.E. (Haryana) 2000]		•
	(a) large size of Br and I		(a) $PbX_2 < SnX_2 < GeX_2 < SiX_2$ (b) $GeX_2 < SiX_2 < SnX_2 < PbX_2$
	(b) strong oxidising character of Pb <sup>4+</sup>	ĺ	· · · · · · · · · · · · · · · · · · ·
	(c) strong reducing character of Pb <sup>4+</sup>		(6) 5212 ( 5512 ( 5512 ( 5512
100	(d) low electronegativity of Br and I   [A DNG 2001]		(d) $SiX_2 < GeX_2 < SnX_2 < PbX_2$
102.	Marsh gas contains: [A.F.M.C. 2001]	114.	Which of the following oxidation states are the most charac-
	(a) $CH_4$ $\square$ (b) $CO_2$ $\square$ (c) $C_2H_6$ $\square$ (d) $N_2$ $\square$		teristic for lead and tin respectively? [C.B.S.E, 2007]
103.			(a) +2, +4
105.	Which of the following is most stable? [C.P.M.T. 2001] (a) $\operatorname{Sn}^{2+}$ $\square$ (b) $\operatorname{Ge}^{2+}$ $\square$		(c) $+2, +2$
	(a) $\operatorname{Sn}^{2+}$ $\square$ (b) $\operatorname{Ge}^{2+}$ $\square$ (c) $\operatorname{Si}^{2+}$ $\square$ (d) $\operatorname{Pb}^{2+}$ $\square$	115.	Which one of the following is present in the chain structure
104			of silicates? [C.B.S.E. 2007]
104.	The state of the s		(a) $(Si_2O_5^2)_n$ $\square$ (b) $(SiO_3^2)_n$ $\square$
			(c) $(SiO_4)^{4-}$
105		116.	Which of the following has the highest calorific value?
105.	Biogas and producer gas are made up of:		[B.H.U. 2007]
	[B.V. (Pune) 2002] (a) biogas contains CO <sub>2</sub> but producer gas does not		(a) Coal gas
	2 1		(c) Producer gas
	(b) producer gas contains CO but not CO <sub>2</sub>	117.	The hybrid state of carbon atoms in C <sub>60</sub> molecule is:
	(c) both biogas and producer gas have $N_2$		(a) $sp$ $\square$ (b) $sp^3$ $\square$
100	(d) all the three above		(c) $dsp^2$ $\Box$ (d) $sp^2$ $\Box$
106.	Me <sub>2</sub> SiCl <sub>2</sub> on hydrolysis will produce: [I.I.T. (S) 2003]	118.	Litharge is chemically: [A.I.I.M.S. 2007]
	(a) $Me_2Si(OH)_2$		(a) PbO $\square$ (b) PbO <sub>2</sub> $\square$
	(b) $Me_2Si = O$		(c) $Pb_3O_4$
	(c) $-[-O-(Me)_2Si-O-]_n$	110	
107	(d) Me <sub>2</sub> SiCIOH	119.	$\operatorname{SiCl}_4 \xrightarrow{\operatorname{H}_2\operatorname{O}} X \xrightarrow{\operatorname{1000}} Y$
107.	Carborundum is: [B.H.U. 2003]		In the above reaction, X and Y respectively are:
	(a) $Al_2O_3$		[E.A.M.C.E.T. (Med.) 2007]
108.	Which of the following is the composition of solder?		(a) $SiO_2$ and $Si$
100.	[A.F.M.C. 2003]	120	(c) $H_2SiCl_6$ and $SiO_2$ $\square$ (d) $H_4SiO_4$ and $Si$ $\square$
	(a) $Cu + Zn$ $\Box$ (b) $Pb + Sb$ $\Box$	120.	Al <sub>4</sub> C <sub>3</sub> on hydrolysis gives gas.
	(c) $Cu + Sn$ $\Box$ (d) $Pb + Sn$ $\Box$		[J.E.E. (Orissa) 2007]
109.	For making good quality mirrors, plates of float glass are		(a) $CH_4$ $\Box$ (b) $C_2H_6$ $\Box$
102.	used. These are obtained by floating molten glass over a	101	(c) $C_2H_4$ $\Box$ (d) $C_2H_2$ $\Box$
	liquid metal, which does not solidify before the glass. The	121.	Diamond is hard because: [V.I.T.E.E.E. 2008]
	metal used is: [A.I.E.E.E. 2003]		(a) all the four valence electrons are bonded to each carbon
	(a) Hg		atoms by covalent bonds
	(c) Na $\Box$ (d) Mg $\Box$		(b) it is a giant molecule
110.	'A' when added to silica will give 'B'. 'A' and 'B' are:		(c) it is made up of carbon atoms $\Box$
1100	[D.P.M.T. 2007]		(d) it cannot be burnt
	(a) $HF, H_2SiF_4$ $\Box$ (b) $HF, H_2SiF_6$ $\Box$	122.	Among the following substituted silanes the one which will
	(c) $HCl_1H_2SiCl_6$ $\Box$ (d) $HI_1H_2SiL_6$ $\Box$		give rise to cross-linked silicone polymer on hydrolysis is:
111.	In $SiF_6^2$ and $SiCl_6^2$ which one is known and why?		[A.I.E.E.E. 2008]
111.			(a) $R_3$ SiCl $\Box$ (b) $R_4$ Si $\Box$
	[D.C.E. (Engg.) 2007]		(c) $RSiCl_3$ $\square$ (d) $R_2SiCl_2$ $\square$
	(a) $SiF_6^2$ because of small size of F	123.	The incorrect statement/s among the following is/are:
	(b) $SiF_6^{2-}$ because of large size of F		[P.E.T. (Kerala) 2008]
	(c) $SiCl_6^{2-}$ because of small size of Cl		I. NCl <sub>5</sub> does not exist while PCl <sub>5</sub> does.
	(d) $SiCl_6^{2-}$ because of large size of Cl		II. Lead prefers to form tetravalent compounds.

	III. The three C—O bonds are not equal in the carbonate		(c) hydrolysis of (CH <sub>3</sub> ) <sub>2</sub> SiCl <sub>2</sub> followed by condensatio	n —
	ion.		polymerisation	
	IV. Both O <sub>2</sub> <sup>+</sup> and NO are paramagnetic.		(d) hydrolysis of (CH <sub>3</sub> ) <sub>3</sub> SiCl followed by condensation	n
	(a) I, III and IV $\Box$ (b) I and IV $\Box$		polymerisation [	
	(c) II and III	128.	Which of the following statements is not correct?	
	(e) ·IV only □		[J.E.E. (W.B.) 2009	9]
	[Hint: Lead prefers to form divalent compounds due to inert pair		(a) Silicon is used extensively as a semiconductor	
	effect. In carbonate ion, all the three C—O bonds are equal		· · · · · · · · · · · · · · · · · · ·	
	due to resonance.]		· ·	
124.	In silica, SiO <sub>2</sub> , each silicon atom is bonded to:		, -	
	[U.P.S.E.E. (Engg.) 2008]	129.	On heating K <sub>4</sub> Fe(CN) <sub>6</sub> with Conc. H <sub>2</sub> SO <sub>4</sub> gives the gas:	
	(a) two oxygen atoms $\Box$	1	[J.E.E. (Orissa) 2009	
	(b) four oxygen atoms			
•	(c) one silicon and two oxygen atoms			
	(d) one silicon and four oxygen atoms $\Box$	130	Products formed, when Pb(NO <sub>3</sub> ) <sub>2</sub> is heated, are:	LI
125.	C—C bond length is maximum in: [U.P.S.E.E. (Engg.) 2008]	150.	[J.E.E. (Orissa) 2009	61
	(a) diamond			
	(c) naphthalene $\square$ (d) fullerene $\square$			
126.	and financial section of the contract of the c	121	(c) PbO, $NO_2$ , $O_2$ $\square$ (d) Pb, $N_2$ , $O_2$ $\square$	
	liberated? [C.P.M.T. 2008]	131.	The products of the following reaction are:	
	(a) CO $\Box$ (b) O <sub>2</sub> $\Box$		$SiO_2 + C \xrightarrow{Heat} Products$	
	(c) $CO_2$ $\Box$ (d) $O_3$ $\Box$		[J.E.E. (Orissa) 2010	0]
127.	The straight chain polymer is formed:		2	
	[C.B.S.E. (P.M.T.) 2009]		(c) SiC and CO	
	(a) hydrolysis of CH <sub>3</sub> SiCl <sub>3</sub> followed by condensation poly-	132.	Which of the following has least tendency to undergo	go
	merisation		catenation ? [A.M.U. (Engg.) 201	0]
	(b) hydrolysis of (CH <sub>3</sub> ) <sub>4</sub> Si followed by addition poly-		(a) C	
	(b) hydrorysis or (Crrs/401 followed by addition pory-	1		_
_			(c) Ge $\square$ (d) Sn

#### **Objective Questions for IIT ASPIRANTS**

- 1. A red coloured mixed oxide (X) on treatment with conc. HNO<sub>3</sub> gives a compound (Y). (Y) with HCl produces a chloride (Z)which is insoluble in cold water but soluble in hot water.(Z) can also be formed by treating (X) with conc. HCl. Compounds (X), (Y) and (Z) are:
  - (a) Pb<sub>3</sub>O<sub>4</sub>, PbO<sub>2</sub>, PbCl<sub>2</sub>
- (b) Mn<sub>3</sub>O<sub>4</sub>, MnO<sub>2</sub>, MnCl<sub>2</sub>
- (c) Fe<sub>3</sub>O<sub>4</sub>, Fe<sub>2</sub>O<sub>3</sub>, FeCl<sub>3</sub>
- (d) Fe<sub>3</sub>O<sub>4</sub>, FeO, FeCl<sub>2</sub>

[Hint:  $Pb_3O_4(X)$  is red coloured mixed oxide consisting PbO and

$$Pb_3O_4 + 4HNO_3 \longrightarrow 2Pb (NO_3)_2 + PbO_2 + 2H_2O;$$

$$PbO_2 + 4HCl \longrightarrow PbCl_2 + 2H_2O + Cl_2$$

PbCl<sub>2</sub> is insoluble in cold water but soluble in hot water.  $Pb_3O_4 + 8HCl \longrightarrow 3PbCl_2 + 4H_2O + Cl_2$ 

- 2. An inorganic compound (A) made of two most occurring elements in the earth's crust and used in building construction when made to react with carbon, forms a poisonous gas (B) which is most stable diatomic molecule. Compounds (A) and (B) are:
  - (a) SiO<sub>2</sub>, CO<sub>2</sub>
- (b) SiO<sub>2</sub>, CO
- (c)  $SiO_2$ ,  $N_2$
- (d) CaO, CO<sub>2</sub>

[Hint: SiO<sub>2</sub> is a compound of oxygen and silicon, the two most abundant elements of earth's crust and is used in building

> $SiO_2 + 2C \longrightarrow Si + 2CO$  (poisonous gas and a stable diatomic molecule) ]

 $\operatorname{SnCl}_2 + \operatorname{HCl} + \operatorname{I}_2 \longrightarrow (A) + (B)$ 

The compounds (A) and (B) are:

- (a)  $SnI_2$ ,  $Cl_2$
- (b) H<sub>2</sub>SnCl<sub>4</sub>, HI
- (c) SnCl<sub>4</sub>, HI
- (d) HSnCl<sub>3</sub>, HI

[Hint: SnCl2 decolourises iodine forming colourless HI.

$$SnCl_2 + 2HCl + I_2 \longrightarrow SnCl_4 + 2HI$$

- 4. Bucky ball or buckminsterfullerene:
  - (a) is an allotrope of carbon
  - (b) is referred as C-60
  - (c) has  $sp^2$  hybridized nature and resembles with soccer ball
  - (d) all of the above
- When concentrated H<sub>2</sub>SO<sub>4</sub> is added to K<sub>4</sub>Fe(CN)<sub>6</sub>, CO is evolved. If in place of concentrated H<sub>2</sub>SO<sub>4</sub>, dilute H<sub>2</sub>SO<sub>4</sub> is used, what gas will be evolved?
  - (a) CO

(b) HCN

(d) CO<sub>2</sub>

[Hint:  $K_4Fe(CN)_6 + 3H_2SO_4$  (dil.)  $\rightarrow 2K_2SO_4 + FeSO_4 + 6HCN$ ]

- Which tetrahalide does not act as Lewis acid?
  - (a) CCl<sub>4</sub>

- (b) SiF<sub>4</sub>
- (c) GeCl<sub>4</sub>
- (d) SnCl<sub>4</sub>

[Hint: CCl<sub>4</sub> does not form hexachloro complex as d-orbitals are not present in carbon but rest of the tetrahalides can form hexahalo complexes.]

- 7. A mixture of two gases is formed when an organic acid is heated with conc. H<sub>2</sub>SO<sub>4</sub>. When the gaseous mixture is passed through KOH solution, one gas is absorbed. The unabsorbed gas combines with chlorine and forms a poisonous gas. The organic acid and the two gases evolved with conc.  $H_2SO_4$  are respectively:
  - (a) CH<sub>3</sub>COOH, CO<sub>2</sub>, CO
- .(b) oxalic acid, CO<sub>2</sub>, CO
- (c) HCOOH, CO, H2O
- (d) none of these

[Hint: COOH]
$$\begin{array}{c} \text{Conc.H}_2\text{SO}_4 \\ \text{COOH} \end{array} \xrightarrow{\text{Conc.H}_2\text{SO}_4} \text{CO} + \text{CO}_2 \xrightarrow{\text{KOH}} \text{CO}_2 \text{ is absorbed COCl}_2 \end{array}$$

- 8.  $2 RCl + Si \xrightarrow{Cu \text{ powder}} R_2 SiCl_2 \xrightarrow{H_2O} R_2 Si(OH)_2 \xrightarrow{Polymerisation}$ 
  - (A), (A) is:
  - (a) cyclic silicone
- (b) cross linked silicone
- (c) linear silicone
- (d) none of these

[Hint: See page no. 426]

- 9.  $SiCl_4 \xrightarrow{H_2O} (A) \xrightarrow{Heat} (B) \xrightarrow{+Na_2CO_3}$ (C). The compound (C) is:
  - (a) SiO<sub>2</sub>
- (b) Si
- (c) SiC

$$[\textbf{Hint}: SiCl_4 + H_2O \longrightarrow Si(OH)_4 \xrightarrow{\quad Heat \quad} SiO_2 \xrightarrow{\quad Na_2CO_3 \quad } Heat \quad \\ (A) \qquad \qquad (B)$$

Na<sub>2</sub>SiO<sub>3</sub>]

- 10. When a mixture of air and steam is passed over red hot coke, the outgoing gas contains:
  - (a) producer gas
- (b) water gas
- (c) coal gas
- (d) mixture of (a) and (b)

[Hint: Coke + air  $\longrightarrow$  CO + N<sub>2</sub>; Coke + H<sub>2</sub>O  $\longrightarrow$  CO+H<sub>2</sub>] Steam

- Producer gas
- 11. Lead oxide (PbO) can be dissolved in:
  - (a) HNO<sub>3</sub>
- (c) H<sub>2</sub>SO<sub>4</sub>
- (d) H<sub>2</sub>O

[Hint: PbO dissolves in HNO3 as it forms lead nitrate which is soluble.

$$PbO + 2HNO_3 \longrightarrow Pb(NO_3)_2 + H_2O$$

HCl forms insoluble PbCl2 and H2SO4 forms insoluble PbSO<sub>4</sub>. PbO is insoluble in water also.]

- 12. Which silicon compound is used as lubricant?
  - (a) Asbestos
- (b) Silicone
- (c) Zeolite
- (d) Mica
- 13. A colourless solution (X) gives black precipitate on passing  $H_2S$ . (X) also gives a white precipitate with stannous chloride which gradually changes to grey. What may be (X)?
  - (a) PbCl<sub>2</sub>
- (b) CdBr<sub>2</sub>
- (c) HgCl<sub>2</sub>
- (d)  $Cu(NO_3)_2$

[Hint:  $HgCl_2 + H_2S \longrightarrow HgS + 2HCl$ ;

 $\begin{array}{ccc} HgCl_2 + SnCl_2 & \longrightarrow & Hg_2Cl_2 & \xrightarrow{SnCl_2} & 2Hg \end{array}]$   $\begin{array}{ccc} White & \longrightarrow & Grev \end{array}$ 

14. 
$$CaCO_3(s) \xrightarrow{Heat} (A)(s) + (B)(g)$$

$$+ Carbon \\ heat \\ (C)(s) + (D)(g)$$

$$(C)(s) + H_2O \longrightarrow (E)(g).$$
The compound  $(E)(g)$  is:

(a)  $CO$ 
(b)  $CO_2$ 
(c)  $CH_4$ 
(d)  $C_2H_2$ 

[Hint: 
$$CaCO_3 \xrightarrow{Heat} CaO + CO_2$$

$$(A) \qquad (B)$$

$$CaO + C \xrightarrow{Heat} CaC_2 + CO$$

$$(C) \qquad (D)$$

$$CaC_2 + 2H_2O \longrightarrow Ca(OH)_2 + C_2H_2 ]$$

$$(E)$$

- 15. A white coloured inorganic salt gives the following reactions:
  - (i) It is soluble in water and the solution has sweet taste. The solution turns black in presence of  $H_2S$ .
  - (ii) The salt when heated gives acetone and a yellow coloured residue which is used in paints.
  - (iii) The solution of the salt gives a white precipitate with dilute HCl which is soluble in hot water.

    The inorganic salt is:
  - (a) Ca (CH<sub>3</sub>COO)<sub>2</sub>
- (b) Zn (CH<sub>3</sub>COO)<sub>2</sub>
- (c) Pb (CH<sub>3</sub>COO)<sub>2</sub>
- (d) Ba(CH<sub>3</sub>COO)<sub>2</sub>

- [Hint: The solution of lead acetate is sweet in taste, when HCl is added to its solution, it forms PbCl<sub>2</sub> which is soluble in hot water.
  - Lead acetate on heating gives acetone and lead oxide (yellow residue).

$$Pb(CH_3COO)_2 \longrightarrow CH_3COCH_3 + PbO + CO_2$$
]

- 16. Which of the following bonds is the weakest?
  - (a) Si-Si
- (b) Si--O
- (c) Si-Cl
- (d) Si—H
- 17. Which metal does not form nitrate when heated with conc. HNO<sub>3</sub>?
  - (a) Zn

(b) Mg

(c) Sn

(d) Pb

[Hint:  $Sn + 4HNO_3 \longrightarrow H_2SnO_3 + 4NO_2 + H_2O$ ]

- **18.** Germanium (II) compounds are powerful reducing agents whereas lead (IV) compounds are strong oxidising agents. It is due to:
  - (a) Pb is more electronegative than Ge.
  - (b) the ionisation energy of Pb is less than that of Ge.
  - (c) the ionic radii of Pb<sup>2+</sup> and Pb<sup>4+</sup> are less than those of Ge<sup>2+</sup> and Ge<sup>4+</sup>.
  - (d) more pronounced inert pair effect in Pb than in Ge.

[Hint: Inert pair effect increases in IVth group as the atomic number increases, *i.e.*, the stability of divalent state increases from Ge<sup>2+</sup> to Pb<sup>2+</sup>.]

#### 1. (a) 2. (b) 3. (c) 4. (d) 5. (b) **6.** (a) 7. (b) 8. (c) 9. (d) 10. (d) **11.** (a) 12. (b) 18. (d) 13. (c) 14. (d) 15. (c) 16. (a) 17: (c)

# **Assertion-Reason Type Questions**

In each of the following questions two statements are given as **Assertion** (A) and **Reason** (R). Examine the statements and answer the questions according to the instructions given below:

Mark (a) if both (A) and (R) are correct and (R) is the correct explanation of (A).

Mark (b) if both (A) and (R) are correct but (R) is not the correct explanation of (A).

Mark (c) if (A) is correct but (R) is wrong.

Mark (d) if (A) is wrong but (R) is correct.

Mark (e) if both (A) but (R) are wrong.

- 1. (A) Graphite is a good conductor of heat and electricity.
  - (R) Free electrons are spread out in the structure of graphite.
- 2. (A) Carbon dioxide is a poisonous gas.
  - (R) Carbon dioxide combines with haemoglobin of blood to form carboxyhaemoglobin which is not capable of absorbing oxygen.
- 3. (A) + 4 oxidation state of Pb is less stable than +2 state.
  - (R) PbI<sub>4</sub> is not a stable compound.

- **4.** (A) Carbon forms a large number of compounds.
  - (R) Carbon is found in abundance in nature.
- 5. (A) Both CO<sub>2</sub> and SiO<sub>2</sub> have same structure.
  - (R) CO<sub>2</sub> is a gas while SiO<sub>2</sub> is a crystalline compound.
- 6. (A) Carborundum is used as an abrasive.
  - (R) Its structure is similar to diamond.
- 7. (A) Maximum covalency of carbon is four.
  - (R) Carbon has no d-orbitals in valence shell.
- 8. (A) Lead leaves a black mark on paper.
  - (R) Lead is used for making lead pencils.
- **9.** (A)  $SiF_6^{2-}$  is known but  $SiCl_6^{2-}$  is not.
  - (R) Size of fluorine is small and its lone pair of electrons interacts with d-orbitals of silicon strongly.
- **10.** (A) Silicones are hydrophobic in nature.
  - (R) Si—O—Si linkages are moisture sensitive.
- 11. (A) CO<sub>2</sub> is linear.
  - (R) It is not in sp hybridized state.

[E.A.M.C.E.T. (Med.) 2007]

- 12. (A) Pb<sup>4+</sup> compounds are stronger oxidising agents than Sn<sup>4+</sup> compounds.
  - (R) The higher oxidation states for the group 14 are more stable for the heavier members of the group due to inert pair effect. [I.I.T. 2008]
- 13. (A) Graphite is soft while diamond is very hard.
  - (R) Graphite has three dimensional structure while diamond has planar. [B.H.U. 2008]
- 14. (A) Silica is soluble in HF.
  - (R)  $SiO_2 + 4HF \longrightarrow SiF_4 + 2H_2O$  $SiF_4 + 2HF \longrightarrow H_2SiF_6$

[B.H.U. 2008]
